3.23.P-Th316 Behavioural Response of Terrestrial Crustaceans to Agricultural Microplastics

Primo Zidar[1], Andraz Dolar[1], Salla Kristiina Selonen[2], Cornelis A.M. van Gestel[3] and ***Anita Jemec Kokalj**[1], (1)University of Ljubljana, Biotechnical Faculty, Department of Biology, Slovenia, (2)Finnish Environment Institute (SYKE), Finland, (3)Vrije Universiteit Amsterdam, Netherlands*

Agriculture is one of the most important sources of microplastics (MPs) in soil. Recent studies have shown that the effects of MPs on the survival and reproduction of terrestrial invertebrates are not severe at environmentally relevant concentrations. However, it is unclear whether this also holds for their behaviour. The avoidance behaviour of organisms is considered an environmentally relevant endpoint, as their habitat function is reduced when they avoid contaminated substrates. On the other hand, preference for a contaminated environment increases their exposure to pollutants.

We investigated the behavioural response of terrestrial crustacean woodlice *Porcellio scaber* to MPs derived from two agricultural plastics: black polypropylene ribbon fabric for direct cover to suppress weed growth, and white mulch fleece for frost protection. We performed a 48-hour soil selection test and a 3-hour video recording test. In the 48-hour soil selection test, the animals chose between control and MP-polluted soils, which were housed in two identical test containers connected by a tunnel. The animals were exposed individually and in groups of ten, and their behaviour was assessed as the percentage of animals on the control versus MP-contaminated soil. In the second exposure scenario, individual animals were recorded for 3 hours in transparent pots divided into two equally sized chambers by a barrier with a passage in the centre. The proportion of time on control compared to MP-polluted soil and the activity of the animals on each soil type (locomotion time, animal speed and total path length) were tracked. In both scenarios, the following pairs of exposure concentrations were tested: 0-0, 0 0.05%, 0 0.5% and 0 5% (w/w) MP for 48-hour exposure with additional 0-1% MP for video tracking. In most treatments, the woodlice did not discriminate between the control and the MP-contaminated soils. However, a clear preference for the soil spiked with 5% MPs from the black direct cover was found in the individual exposure. Video recordings of individual isopods confirmed the preference of soil with 5% of this MP, they spent a longer time, and their speed of locomotion decreased while time of locomotion increased on that soil. When exposed to the mulching fabric fleece MPs no soil discrimination was noticed. In conclusion, our results show that some agricultural MPs can influence the behaviour of woodlice.

3.23.P-Th317 Soil Litter Feeders Impacted by Low Concentrations of Microplastics. The Case of Earthworms, Ants and Slugs in the MINAGRIS PROJECT

Elizabeth Racicot and ***Esperanza Huerta Lwanga**, Wageningen University, Netherlands*

Plastic pollution is one of the international problems that is facing our modern society. Macro, meso and microplastics are found in different types of terrestrial environments, from agricultural soils to parks, or conservation areas. In the EU MINAGRIS project, we try to assess and understand the interaction between plastic particles with different stressors at different soil conditions. Therefore in WP4, one of the tasks was consecrated to the assessment of the impact of microplastics on soil fauna. The main objective of this task was to assess mortality, growth rate and behavior of different soil invertebrates. At laboratory, with control conditions of temperature and moisture, experiments were performed with 3 main types of soil organisms: earthworms (anecic, epigeic and endogeic), ants and slugs; 3 types of soils were used (sandy, sandy loam and clay soils) and 3 types of plastics (starch based, PBAT and polyethylene) were implemented with very low microplastic concentration doses (0.01% and 0.1%). Finally the main results reveal that biodegradable plastics together with pesticides might impact anecic earthworm growth rate significantly at 7 days, compared with other type of plastics. At the long term (60 days), anecic earthworms seem also be impacted with fossil-based biodegradable plastics (PBAT). Ants' behavior are perturbed with the presence of plastic particles, separating the plastic particles from the rest of the food materials. Slugs, like litter feeders lose weight with leaves mixed with low concentrations of microplastics. No significant differences were observed between endogeic earthworms with low concentration of microplastics. Preliminary results indicated that low concentrations of microplastics also impact soil fauna. More data analysis is needed for connecting the impact of low concentration of microplastics on soil ecosystem services provided by soil fauna.

3.23.P-Th319 Microplastics Derived from Agricultural Mulch Films Indirectly Affect Terrestrial Organisms and Microbial Activity Due to Altered Soil Properties

***Špela Železnikar*[1]*, Andraz Dolar[2], Anita Jemec Kokalj[2], Marina Pintar[1], Vesna Zupanc[1], Tjasa Danevcic[3], Ines Mandic-Mulec[3], Tina Petrisic[2] and Damjana Drobne[2], (1)University of Ljubljana, Biotechnical Faculty, Department of Agronomy, Slovenia, (2)University of Ljubljana, Biotechnical Faculty, Department of Biology, Slovenia, (3)University of Ljubljana, Biotechnical Faculty, Department of Microbiology, Slovenia*

Microplastics (MPs) in soil bind minerals and organic matter, integrating into the soil matrix. This incorporation can alter soil physical properties, such as bulk density, aggregate stability, and water-holding capacity. Our previous results showed alterations in soil physical parameters due to the presence of MPs derived from agricultural mulch films. Given that altered soil properties could have impacts on soil biota, our present research investigates if selected MPs affect terrestrial organisms and soil microbial activity. We exposed terrestrial crustacean *Porcellionides pruinosus* (Crustacea, Isopoda) to soil with three types of MPs (LDPE, PBAT, starch-based PBAT) at 1%, w/w concentration in sandy loam soil for 14 days. Pots used in the experiment were filled with dried and sieved with sandy-loam soil and mixed with MP. Pots were placed in randomized order in specially designed pools with gravel and jute at the bottom to facilitate wetting and buried in soil. After wetting organisms were introduced to the pots for a 14-day exposure period.

After the experiment, we analysed the survival of the test organisms, the level of selected immune parameters (total haemocyte count, differential haemocyte count, haemocyte viability and phenoloxidase-like activity), the activities of two stress-related enzymes (AChE: acetilholinesterase and GST: glutathione S-transferase) and the metabolic activity (electron transfer system activity, ETS). In addition, the microbial activity i.e. CO2 production in the soil samples taken from the control and the soil treated with MPs was analysed.

The survival of the test animals was not affected by the exposure to three different types of microplastics in the soil compared to the control group. We also did not observe any changes in enzyme activities for all tested MPs. However, we observed a significant decrease in the total haemocyte and phenoloxidase-like activity in *P. pruinosus*, after exposure to 1% STARCH in soil. These results coincide with increased microbial activity in the soil with added PABT MPs and especially Starch based MPs. We speculate that the observed alterations at the immune system level of a *P. pruinosus* are due to the indirect effects of MP exposure. This implies that selected terrestrial organisms could be employed to measure the indirect effects of plastic pollution, which is of significant importance for properly assessing the impact of plastics on the environment.

3.23.P-Th320 Sublethal Effects of Polypropylene Agricultural Microplastics on *Eisenia Andrei*
*Salla Kristiina Selonen[1], **Vili Saartama**[1] and Jari Haimi[2], (1)SYKE, Finland, (2)University of Jyväskylä, Finland*
We examined the avoidance behavior of the earthworm *Eisenia fetida* when exposed to agricultural plastics, specifically two types P8 (polypropylene [PP] ribbon fabric for direct cover) and P9 (PP mulching fabric), under controlled conditions. With the rapid increase in plastic use since the 1950s, over 300 million tons of plastics are produced annually. Plastics, composed of long-chain organic polymers, degrade slowly in the environment into microplastics (<5 mm), posing risks to ecosystems. In agriculture, plastics are extensively used for mulching, packaging, and irrigation, leading to their accumulation in soils. Microplastics in agricultural soils can persist for centuries, raising concerns about their ecological impacts.
The experiment was conducted using ISO 17512-1:2008(E) standard. Soils mixed with microplastics at concentrations of 0.05%, 0.5%, and 5% were placed in aluminum trays, with clean soil on the opposite side. Worms were introduced at the center and allowed to choose between the sides. After 48 hours, the distribution of worms was counted to assess avoidance behavior.
Results showed that at concentrations (0.05 0.5%) of P8, no significant avoidance was observed. However, at 5%, over 90% of worms preferred the clean soil. For P9, avoidance was evident even at 0.5%, with over 75% of worms choosing clean soil, and at 5%, over 90% displayed avoidance. These findings indicate that earthworms are more sensitive to certain types of plastics and respond strongly to higher concentrations of microplastics.
The avoidance behavior of earthworms has significant ecological implications. Earthworms play critical roles in maintaining soil health by enhancing organic matter decomposition, nutrient cycling, and soil structure. Their displacement from contaminated soils could disrupt these ecosystem services, potentially degrading soil quality. While average microplastics concentrations in agricultural soils are typically lower than the highest tested levels, some hotspots may reach or exceed such concentrations.
The study underscores the risks posed by the increasing use of agricultural plastics. The variability in earthworm responses to different plastic types suggests that the diversity of plastics used in agriculture could result in varying impacts on soil organisms. As the issue is cumulative, it highlights the need for further research and sustainable practices to mitigate the long-term effects of microplastics on agricultural ecosystems.

3.23.P-Th321 First Assessment of the Impact of Plastics on Soil Communities: A Case Study in France
*Melanie Davranche[1], Anne-Catherine Pierson-Wickmann[1], Stephane A.P. Derocles[2], David Renault[2], Clarisse Cadot[2] and **Angeline Juif**[2], (1)UMR CNRS 6118 GEOSCIENCES Rennes, Universite de Rennes, France, (2)UMR CNRS 6553 ECOBIO [Ecosyst mes, biodiversite, evolution], Universite de Rennes, France*
Plastics presence and degradation in soils constitutes a growing environmental concern, with significant implications for soil health and biodiversity. Despite extensive research on plastic pollution in marine and freshwater environments, there is an urgent need to improve our understanding of the impacts of plastic debris in terrestrial habitats, where microplastics and nanoplastics can be found in greater quantities than in aquatic ecosystems. Agricultural soils are of particular concern, as they are end-receivers of several sources of plastics, such as compost from household waste or sewage sludge. Furthermore, these soils which cover about 25% of Europe's soil surfaces are of crucial importance for global food production, and provide support for key ecological processes such as carbon storage and nutrient cycling.
The present work was performed in an agricultural field which received compost from household wastes; and the composition of communities of ground beetles, spiders and plants was examined.
The study site is located in France and comprised two adjacent plots in fallow: one plot was contaminated with household waste compost enriched in plastic particles, while the second plot free of compost serves as control. We used pitfall traps to assess the activity density of ground beetles and spiders. We also used

vegetation quadrats to assess plant cover. Diversity indices were then calculated on the data of species collected.
Species richness and Shannon's diversity were significantly higher in the contaminated plot compared to the control for the communities of spiders, ground beetles and plants. Also, Pielou's evenness was significantly higher in the contaminated plot compared to the control for the communities of plants. These results suggest that plastics in the soil could affect - directly or indirectly - the composition of spiders, ground beetles and plants communities, and the dominance of certain plant species. Additionally, we examined the functional diversity of the spider communities, and the presence of plastics did not affect spiders' community weight means for size or hunting strategy.
Our study provides rare and novel field data on soil plastic contamination and its impact on aboveground communities, as it is the first study of this kind to our knowledge. It sheds new light on the impact of plastic waste on soil ecosystems, and it could be a starting point for a deeper understanding of the response of communities to plastic pollution.

3.23.P-Th322 Degradation Behaviour of a Seed Coating in an OECD TG 307 Simulation Test and Quantification with Pyrolysis-GC/MS and FFF-MALS
Julia Marie Peters[1]*, Dieter Hennecke*[2]*, Andreas Schaffer*[3]*, Annika Jahnke*[4] *and Michael Huben*[2]*, (1)Fraunhofer Institute for Molecular Biology and Applied Ecology (IME), Germany, (2)Ecological Chemistry, Fraunhofer Institute for Molecular Biology and Applied Ecology (IME), Germany, (3)Institute for Environmental Research (IFER), RWTH Aachen University, Germany, (4)Department of Ecological Chemistry, Helmholtz Centre for Environmental Research (UFZ), Germany*
The fate of polymers is in the focus of the new restriction (Commission Regulation (EU) 2023/2055) issued by the European Commission on microplastics intentionally added to products used for specific purposes. The criteria for restriction are based on the biodegradability of polymers, which is determined according to OECD test guidelines (TG), for example TG 301 and TG 307. Only synthetic polymers are considered in the restriction. Therefore, producers strive to shift to natural polymers, which are considered to be biodegradable by default, and synthetic polymers which show proof of fast biodegradation (i.e. ?60% mineralisation within 28 days, measured in TG 301). The degradation rate and formed degradation products of respective polymers are often unknown. While natural polymers are considered degradable by default this does not mean that they would pass those degradation tests. Also, in our project an OECD TG 301 test has shown that combining different natural polymers in a seed coating resulted in less than 60% mineralisation in 28 days. In order to address the biodegradability of the seed coating a simulation test (OECD TG 307) was chosen as it would be foreseen in the restriction. For this purpose, the main polymer sodium alginate was radiolabelled with 14C-Bromethanol and the seed coating was produced with the 14C-radiolabelled material. The 14C-radiolabel allows to follow degradation processes in the complex soil matrix and to determine mineralization (CO2 formation) even at environmental relevant polymer concentrations. Further, a density separation was developed to quantify the degradation of the polymeric seed coating as well as measure a shift in the molar mass. During specific time intervals the seed coating is separated and analysed with pyrolysis-gas chromatography and mass spectrometry (GC/MS) and field-flow fractionation coupled to a multi-angle light scattering detector (FFF-MALS) and radio-detection. As the seed coating degraded using oxidative extraction methods, a density separation was used. Often zinc chloride solution is utilized for microplastic density separation but we observed degradation of the seed coating using this salt. Instead, sodium iodide was chosen for density solution reaching densities up to 1.9 g/cm3. A separation recovery of 87.8 ±5.3 % was achieved with this method. Details of the OECD TG 307 test, analysis of the polymer concentration with pyrolysis-GC/MS, and the molar mass shift with FFF-MALS will be presented.

3.23.P-Th323 Microplastic Generation and Changes in Functional Chemistry Under the Combined Effects of UV and Thermal Oxidation with Abrasion
Andrea Arredondo Navarro[1]*, Justin Scott*[2]*, Xuewen Wang*[2]*, Dulce Gallardo-Owens*[2]*, Gwen Tippling*[2]*, Matteo Minghetti*[3]*, Eliane El Hayek*[4]*, Jose M. Cerrato*[4] *and* ***Jorge Gonzalez-Estrella***[2]*, (1)Oklahoma State University, United States, (2)Oklahoma State University, United States, (3)Integrative Biology, Oklahoma State University, United States, (4)University of New Mexico, United States*
This study compares the generation of microplastics (MPs) from plastics oxidized by thermal and ultraviolet (UV) radiation processes. Our group has found that open-pit waste burning in underserved areas contributes to MPs generation showing signs of thermal and UV oxidation. However, the mechanisms behind the MP generation under these two oxidation processes are not fully understood. The plastics selected in this study include low density polyethylene (LDPE), polypropylene (PP), and polystyrene (PS), and were all obtained as consumer products. To understand changes in functional

chemistry, MP generation and reactivity in aqueous media, thermally, ultraviolet (UV), and non-oxidized plastics were subjected to mechanical abrasion conditions that promote the fragmentation of plastic pieces into MPs. We used Attenuated Total Reflectance-Fourier Transform Infrared (ATR-FTIR) spectroscopy to analyze the functional group and structural changes in the plastics before and after oxidation and before and after abrasion. Microplastic generation was quantified in terms of particle count using fluorescence microscopy, and in terms of weight with pyrolysis gas chromatography/mass spectrometry (Py-GC-MS). Results show that UV and thermal oxidation increase carbonyl (C=O) and ester (C-O) functional groups, evidenced by higher carbonyl index (CI) values. Abrasion further modifies the chemical structure, introducing reactive oxidative sites due to polymer chain scission, as reflected by distinct changes in ATR-FTIR spectra. MP generation was highest in UV-treated plastics subjected to abrasion, with LDPE and PP showing significant weight loss and fragmentation. In contrast, PS exhibited resistance to abrasion post-oxidation, likely due to alterations in its glass transition temperature (Tg). These findings highlight the combined impact of oxidation and mechanical abrasion on plastic degradation. The chemical changes observed may influence the environmental behavior, toxicity, and interactions of MPs, particularly in ecosystems affected by open burning and unmanaged plastic waste.

Disclaimer/Disclosure: This study was funded by the National Institute on Minority Health and Health Disparities (Award Number P50MD015706), the National Science Foundation (Award Number CAREER 2338225). Justin Scott was supported by the National Institute of Environmental Health Sciences (Award Number: 1R15ES034901-01).

3.23.P-Th324 Optimizing Microplastic Monitoring Techniques Using an Experimental Mass Based Approach

***Haley Johnson*[1]*, Andrew Gray[1], Vamsi Ganti[2] and Leah Thornton Hampton[3], (1)University of California, Riverside, United States, (2)University of California, Santa Barbara, United States, (3)Southern California Coastal Water Research Project, United States*

Microplastics are a diverse suite of ubiquitous contaminants ranging from 1 micron to 5 millimeters that include a wide array of morphological features. Developing a standard operating procedure to collect microplastics during stormflow conditions is essential to harmonize data across regions and waterways. There is currently no standard protocol for collection and analysis of microplastics, making comparisons between studies difficult to assess. This study aims to develop a standard for microplastic collection in river stormflow for the state of California using a flume and environmental river samples. Multiple sampling techniques, from simple surface grab to sophisticated suspended sediment net sampling, were compared using four polymer types with different densities in an experimental flume using a mass based analysis approach. Various depths, velocities, and sampling orientations were tested and analyzed to compare sampler performance under several hydrologic conditions. We hypothesize that depth integrated isokinetic approaches will result in the most representative sample across the flow field, as surface and mid depth samples will not capture all transport modes. In addition to the experimental work, we used these same sampling methods in Los Angeles County rivers to compare with environmental data in urban systems. This standard will assist with consistent data across studies and allow for impactful comparisons globally, generate a better understanding of microplastic fate and transport, and produce more accurate flux models from coastal watersheds to the marine environment. Our recommendations will be used by state municipalities and researchers to monitor microplastics across California.

3.23.P-Th325 Improving Controlled Separation of HDPE and PP via Electron Beam Technology for Detection of Microplastics

***Oliver Kretschmar*[1]*, Lucas Kurzweg[2], Uwe Gohs[1], Marc-Peter Schmidt[1] and Kathrin Harre[3], (1)University of Applied Sciences Dresden (HTW Dresden), Germany, (2)Chemical Engineering, University of Applied Sciences Dresden (HTW Dresden), Dresden, Germany, (3)Agriculture/Environment/Chemistry, University of Applied Sciences Dresden (HTW Dresden), Dresden, Germany*

Although microplastic pollution is a global environmental issue, analysis remains a challenge. While most established methods, such as Raman microscopy and TED-GC-MS, are very time-consuming and costly, differential scanning calorimetry (DSC), after prior enrichment by electrostatic separation, requires less time and investment and is therefore considered a routine-capable method. Application of electrostatic separation and DSC enables Microplastic-Analysis in particular matrices. A DSC measurement investigates the phase transitions in semicrystalline polymers as they are heated or cooled. During melting or crystallization, a polymer-specific signal is generated, allowing the identification and quantification of

an unknown polymer sample. However, the signals of some critical polymer pairings, such as HDPE and PP, overlap when both are present simultaneously, making their parallel identification and quantification challenging.
To address this issue, the effect of electron beam treatment on the physicochemical properties of these polymers and their controlled fractionation in electrostatic separation was investigated. The results demonstrated that a controlled fractionation of HDPE and PP in a corona roller separator is possible after electron beam pretreatment. The absorbed primary charges from the initial electron beam treatment induce distinct charging properties which persist for at least two days (the maximum duration studied), that influence the behavior of polymer particles during electrostatic separation. Under optimal irradiation and storage conditions, a controlled separation of HDPE and PP particles is feasible, enabling the quantification of polymers using DSC. Challenges remain in accounting for the influence of electron beam treatment on the DSC signal, scaling up the particle mass in the separation process. Additionally, further investigation is needed to determine whether the effects of electron beam treatment are applicable to other critical polymer pairings, such as PET/PVC and PET/PA6.
The findings provide valuable insights into the differential enrichment of HDPE and PP and are relevant not only to the analysis of microplastics but also to the optimization of plastic recycling, particularly regarding the pretreatment of plastic waste with electron beam radiation.

3.23.P-Th326 Abundance and Characteristics of Anthropogenic Litter Along the Tanzanian Shores of the African Great Lakes: Volunteer Involvement, Outreach and Stakeholder Engagement
Bahati Mayoma[1], Mamlo Abdallah[2], Hellena Silas[3], Zagalo Emanuel[3], Edith Lukanga[4], Kitogo Lawrence[4], Adventina Edson[4], Deo Simbila[4], Arthur Mugema[4], Paul Matonya[5], Fanuel Kasenen[6], Christina Sorensen[7], Conrad Sparks[8] and ***Farhan R. Khan**[9]*, *(1)University of Dar es Salaam, "Tanzania, United Republic of", (2)Environmental Conservation Community of Tanzania, "Tanzania, United Republic of", (3)ARENA, "Tanzania, United Republic of", (4)EMEDO, "Tanzania, United Republic of", (5)Sustainable Ocean Alliance, "Tanzania, United Republic of", (6)Mwanza City Council, "Tanzania, United Republic of", (7)Norwegian Institute for Water Research (NIVA), Norway, (8)CPUT, South Africa, (9)NORCE, Norway*
Environmental pollution due to mismanaged anthropogenic litter is one of the most pressing issues facing the world today. To reduce existing environmental burdens of litter, clean-up events have increased in popularity. Here, we report on the results of the Clean Shores, Great Lakes project, in which we conducted 69 volunteer-based clean-ups along the Tanzanian shorelines of the African Great Lakes (Victoria, Tanganyika, and Nyasa [also known as Lake Malawi]). A total of 5483 volunteers engaged with the project across all clean-up sites, collecting 431,328 pieces (25981 kgs) of anthropogenic litter. Expressing the data as normalized to area (items m-2) or effort (items individual-1 hour-1) revealed that the interpretation of a polluted site varies with units. Litter abundance varied from 0.06 to 13.89 items m-2 and 5.2-706 items individual-1 hour-1. Plastics were the major litter type constituting 75% of all litter (mean = 74.2 ± 12.5 % across all sites), while clothing (10.9 ± 9.5 %) and fishing gear (3.7 ± 5.2%) were also prevalent. Two items constituted > 40 % of all collected litter, namely plastic beverage bottles (average 23.7 ± 17.1 %, range 0-72.9 %) and plastic bags (average 19.7 ± 13.2 %, range 1-50.3 %). Prioritizing intervention measures on these two items could reduce litter leakage significantly. Further, a holistic approach was undertaken through voluntary engagement, citizen science involvement, stakeholder dissemination and school visits to increase public awareness. Clean-up data when disseminated to relevant policymakers and stakeholders can motivate activity for the environmental management of anthropogenic litter and plastic pollution.

Disclaimer/Disclosure: The Clean Shores, Great Lakes project was funded by Handelens Miljøfond (Grant number 12526).

3.23.P-Th327 Reducing Microplastic Emissions from Aquaculture Through Optimisation of Infrastructure and Cleaning Technologies
***Andy Booth**[1]*, *Stefania Piarulli[1], Heidi Moe Fore[1], Nina Bloecher[1], Alessio Gomiero[2], Torstein Kristensen[3], Astrid Lunde[4] and Hanne Hjelle Hatlebrekke[1], (1)SINTEF Ocean, Norway, (2)NORCE, Norway, (3)Scale Aquaculture AS, Norway, (4)Brynslokken AS, Norway* The aquaculture industry is dependent upon large amounts of plastic infrastructure, which can contribute to the direct release of microplastic (MP) into the marine environment. Net cleaning procedures can cause net abrasion, potentially leading to coating particles and polymer fibres being released. Here, we apply safer and sustainable by design principles to quantify the reduction of MP emissions by introducing feasible reduction measures through the selection of specific combinations of net polymers, coatings and cleaning technologies. A laboratory experiment simulating in situ mechanical abrasion was performed to quantify

and compare MP release from different nets. The tested net types included new Nylon, HDPE, Dyneema, and Entex net, used nylon net, as well as two coating types, standard and premium, used to extend net life. The collected particulate material was quantified and characterised using gravimetry, microscope imaging and pyrolysis GC-MS. Nylon nets release higher quantities of MP compared to HDPE, Dyneema and Entex, while coatings interacted differently with the various net materials. There was no change in MP release from coated Dyneema nets, but an increased particle release from the coated nylon nets. For nylon nets, used materials released more MP than new ones, with used nylon net samples from different depths exhibiting different particle release profiles. The results indicate reduced MP emissions from PE based nets compared to nylon. However, it is important to note that nylon nets can be chemically recycled, while this is not currently possible for PE nets (although testing for mechanical recycling is ongoing). In a field study, a partial aquaculture pen net comprised of used nylon net and coated new nylon net panels was constructed and deployed at sea. Each type of net material was subjected to 3 different washing techniques simulated approx. 10 months at sea: (i) a standard high pressure cleaner (Stealth Cleaner), (ii) a cavitation cleaner (Meox cleaner), and a brush-based grooming ROV (Watbots ROV). Water samples (min 200 L per replica) were pumped through a stack of large surface stainless steel filters with mesh sizes of 300 and 10 µm. The samples are currently being processed and analysed by imaging µFTIR to quantify and characterise the MP emissions from each combination of net type and cleaning technology. Preliminary results indicate a predominance of nylon MPs, but a broad range of other polymer types are also present.

3.23.P-Th328 Assessing the Microplastic Contribution from Sewage Sludge to Agricultural Soils with Regular Sludge Application

Thilakshani Atugoda[1]*, Ceri Lewis*[2]*, Richard Brazier*[1]*, Vinuela Ruth*[3] *and Bob Barnes*[4]*, (1)Department of Geography, University of Exeter, United Kingdom, (2)Department of Biosciences, Geoffrey Pope Building, University of Exeter, United Kingdom, (3)South West Water, United Kingdom, (4)Climate Change and Resource Efficiency, Chief Scientist's Group, Environment Agency, United Kingdom*

The transition to sustainable agriculture emphasises the adoption of organic alternatives, such as biosolids, in place of inorganic fertilisers that contribute to the circular economy. Biosolids are widely utilised in the United Kingdom as a fertiliser for replenishing organic matter in agricultural soils. However, their application has been identified as a potentially significant pathway for microplastic (MP) contamination in terrestrial environments. This study aims to evaluate the presence and concentration of microplastics in soil obtained from farmland soils in Southwest England, which have records of biosolid application history. Soil from agricultural land that has not had biosolid for a prolonged time, but has an otherwise similar land use history was used as controls for identifying non-sludge-derived microplastics. The collected soil samples were digested using Fenton's reagent, and a series of density separations using saturated ZnCl2 were carried out to extract microplastics from the soil matrix. The biosolid amended soil accounted for 80-95% of the MP fibres and 6-20% of the MP fragments recovered. The average concentration of microplastics was 4,465 particles per kilogram of dry weight of soil, although there was significant variability across different fields, with values ranging from 1,200 to 11,400 particles per kilogram of dry weight. This variation highlights the complexity of microplastic contamination in soils affected by biosolid application. Additionally, soil samples were analysed for other properties such as water-holding capacity, pH, organic matter, NH3, NO-3, NO-2, and PO43-. Organic matter was measured using the loss on ignition method, and nutrient analysis was performed using a Skalar Bluvision discrete analyser. The average organic matter, NH3, NO-2 and NO-3 content for biosolid applied fields were 10.38 ± 1.18 %, 1.11 ± 0.48 mg/kg, 0.05 ± 0.02 mg/kg, and 48.57 ± 22.30 mg/kg and for control fields were 11.83 ± 1.32 %, 1.45 ± 0.06 mg/kg, 0.08 ± 0.07 mg/kg, and 36.60 ± 15.47 mg/kg, respectively. The higher concentrations of fibres in soil primarily come from synthetic textiles in sewage, and their tendency to entangle in soil aggregates contributes to their persistence. Aside from biosolid application, soil properties varied across the fields due to factors such as soil type, complexity of the matrix, geographical distribution, and land use.

Disclaimer/Disclosure: The authors would like to acknowledge NERC ECORISC CDT and South West Water for providing funding and support.

3.23.P-Th329 Ageing Conditions Alter the Effects of Leachates from Tire Wear Particles on Soil

Shin Woong Kim[1], *Yanjie Zhu*[2], *Sofia Barili*[3], *Gulshat Abdullayeva*[4], *Yaqi Xu*[2], *Chang-Beom Park*[1] *and Matthias C. Rillig*[5], *(1)Center for Ecotoxicology and Environmental Future Research, Korea Institute of Toxicology, "Korea, Republic of", (2)Institute of Biology, Freie Universitat Berlin, China (Mainland), (3)Institute of Biology, Freie Universitat Berlin, Italy, (4)Institute of Biology, Freie Universitat Berlin, Turkmenistan, (5)Institute of Biology, Freie Universitat Berlin, Germany*

Tire wear particles (TWP) are one of the most abundant types of microplastics, and have emerged as a main contributor of microplastic pollution. Given the fact that tires are a complex mixture of rubber and chemical additives, previous research on assessing the effects of TWP has been mainly based on the leached fractions. Although physicochemical properties of TWP (e.g., chemical constituents or surface properties) and environmental conditions (e.g., UV, pH, temperature and salinity) are well known as main factor influencing the chemical leaching processes, there is a knowledge gap regarding different ageing conditions due to the lack of empirical data. In this study, we established a soil laboratory experiment using TWP leachates with three different ageing treatments (mechanical-, thermal-, and UV-ageing), and measured nine soil parameters (soil microbial activities and physicochemical properties) to investigate how ageing conditions influence the effects of TWP leachates on soil. We found that TWP leachates of different ageing treatments induced distinct effects compared to leachates from pristine TWP, and each ageing treatment showed different response patterns in different soil parameters. Compared to the non-aged treatment, the leachates of the mechanical-ageing treatments affected soil C/N ratio and ?-1,4-N-acetyl-glucosaminidase activity, while the leachates of thermal-ageing treatment influenced soil litter decomposition, water stable aggregates, and pH. Our study provides solid evidence that the ageing conditions can alter the effects of TWP leachates on soil. This has further refined our knowledge of the ecological impacts of TWP, and highlighted the necessity of considering ageing condition as a crucial factor investigating the environmental effects of TWP.

3.23.P-Th330 Is “Compostable” also “Eco-Friendly”? – The Fate and Effects of Compostable Plastic Bags After Composting

Julia Naima Moller, *Wageningen University and Research (WUR), Netherlands*

Compostable plastic products are commonly perceived as an environmentally friendly alternative to conventional plastics. However, European standard tests to certify a material as compostable do not reflect realistic conditions in municipal composting facilities. Studies have shown that high numbers of microplastics derived from compostable plastic products remain in the compost and may have a higher resistance to enzymatic degradation than previously assumed. The compost containing the residual biodegradable plastic fragments is then distributed to agricultural fields. It has also been shown that compostable plastic products can contain chemicals that leach from the product over time. Negative effects of these leachates have been reported for aquatic organisms, but studies concerning the effects on soil systems are lacking.

In this recently started project we aim to determine if residual microplastics derived from already composted compostable plastic bags will degrade under field conditions within two years. For this we will characterise and quantify the biodegradable plastic fragments in the compost from a Dutch municipal composting plant. The characterised compost will then be placed in mesocosms on a Dutch field and sampled at the beginning of the experiment and after 3, 6, 12, 18 and 24 months. These samples will be analysed via Fourier Transform Infrared (µ-FTIR) spectroscopy for a particle based monitoring as well as NMR (Nuclear Magnetic Resonance) spectroscopy for a mass-based monitoring, allowing comparisons of mass and particle reduction.

Further we will assess how the chemical leachate and fragments from compostable plastic products affect earthworm fitness, reproduction and development.

By May 2025 we will be able to present our methodologies, and the first results of the degradation process after 3 months and the results of the earthworm reproduction tests.

As the use of compostable plastic products is expected to increase significantly in the coming years, we consider it essential to close the knowledge gap on the fate and effects of compostable plastic particles after they have undergone the conventional composting process and end up in agricultural fields. This study would then be one step towards determining if compostable plastics are indeed environmentally friendly and in compliance with the European Green Deal, the Zero Pollution Action Plan and the European Soil Strategy.

Disclaimer/Disclosure: This project is funded by the Dutch Research Council (NWO) in the scope of the NWO Talent Program (project number: VI.Veni.232.175).

3.23.P-Th331 Towards Implementation of an Environmental Risk Assessment Framework for Microplastics in the Dutch Policy Context

Elmer Swart[1]*, Peter van Breemen*[1]*, Mirjam Schuijff*[1]*, Albert Koelmans*[2] *and Joris T.K. Quik*[1]*, (1)RIVM, Netherlands, (2)Wageningen University and Research (WUR), Netherlands*

Microplastics are ubiquitous in the environment, including in soils, and pose a hazard to organisms. Environmental risks of microplastics remain uncertain, especially for soil ecosystems. In part, this uncertainty relates to the availability of reliable and relevant data and the extent to which risk assessment approaches can deal with the complexity of microplastics pollution. Environmental risk assessments (ERA) are at the basis of policy on chemical pollution. It is therefore important that an ERA framework for microplastics meets policy makers' needs for policy on microplastics and that it is supported by the scientific community. In this study we take an ERA approach developed by researchers from the Wageningen University (the Netherlands) and, through a series of workshop and a questionnaire, assess whether the approach fits the needs of Dutch policy makers and whether it is supported by members of the scientific community. The original focus of the study lies with the soil system. However, the consulted experts and policy makers were from various backgrounds and so the study outcomes are likely relevant to multiple compartments/policy domains. Among Dutch policy makers from national government we identified a clear need for an ERA of microplastics, although underlying reasons varied and included, among others, the setting of environmental quality standards, creating support for microplastics policies and identifying hotspots of pollution. The policy makers stressed the importance for providing perspectives for policy actions. A questionnaire targeted at scientific experts on the topic of ERA of microplastics showed that generally, there was broad support for use of the approach developed by the researchers from Wageningen University for (soil) microplastics policies. However, there are different perspectives on attributes of ERA of microplastics, for example, on the importance of including chemical effects and the specific needs for further development of the approach. Additional scientific perspectives on the topic will be collected via an online workshop. The findings of this study will lead to a better understanding of perspectives on ERA, how it meets the needs of Dutch policy makers, and specifically what else needs development or studies. Based on the input collected we will formulate and present recommendations to further science-based environmental policy on microplastics.

Disclaimer/Disclosure: This study was funded by the Dutch Ministry of Infrastructure and Water Management.

3.23.P-Th332 Ecological Risk Assessment Framework for Microplastics in Agricultural Soils Amended with Biosolids

Asta Hooge Poulsen[1]*, Tony R. Walker*[2] *and Kristian Syberg*[3]*, (1)Roskilde University, Denmark, (2)Dalhousie University, Canada, (3)DSE, Roskilde University, Roskilde, Denmark*

This study conceptualizes a framework for ecological risk assessment of microplastics (MPs) in agricultural soils amended with biosolids. MPs in biosolids pose risks to soil biota, affecting soil health. The study highlights the complexity of assessing MP risks, considering not only MPs abundance, but also properties such as size, shape, and type. To develop this framework for ecological risk assessment of MPs in agricultural soils amended with biosolids, a literature review was conducted to systematically assess effects of different MPs properties on soil organisms. Earthworms, springtails, and the microbiome were considered as receptors. The study highlights the importance of understanding MPs fate in soil, since effects on soil biota can be time dependent. Furthermore, results show that organisms respond differently to similar MPs properties, increasing the complexity of assessing MPs risks in terrestrial ecosystems. This complexity also relates to MPs effects on soil properties, and indirect effects on soil biota. Further research is needed to address knowledge gaps for effects of specific MPs properties to better assess and manage ecological risks in agricultural systems.

3.23.P-Th333 Investigating Phytoremediation Potential via Retention Modules for Microplastic Contamination in Soils

***Pauline Seidel**, Xhoen Gjashta, Maurice Hauffe, Lucas Kurzweg, Tilmann Priebe, Sabrina Selinger, Lukas Birkigt, Arne Cierjacks and Kathrin Harre, HTWD, Germany*

Microplastics (MPs) enter the environment through manifold direct and diffuse pathways, posing risks to flora, fauna, humans and entire ecosystems. One of the major sinks for MPs are soils. The common research opinion is that MPs, once reached into the soil, cannot be extracted anymore. Therefore, we want to investigate the chances and limitations of phytoremediation further. So far, there are only a few studies on phytoremediation in terrestrial systems, mostly limited to laboratory experiments. Our goal is to develop wooden modules, designed to retain MPs in floodplains as their soils are known to be highly polluted with MPs possibly entering the ground- and drinking water.

As preliminary studies, we mapped MP contamination of the Elbe river floodplains along several transects down to 30 cm depth to identify small-scale MP hotspots. Additionally, we investigated the intake capacity of plant roots by a 3-month laboratory experiment with osiers [*Salix viminalis*], planted in sand which we spiked with inhouse-MP-reference-particles. Per planting pot, we used 0.75 mg of MP in 2 kg sand; either LDPE or PA with particle sizes of 500-600 µm or 650-1050 µm, respectively. As a proof of concept, we built wooden frames (30x30x10 cm), filled up with sand or loam. In each of these retention modules, we planted common osiers [*Salix viminalis*] or purple osiers [*Salix purpurea*] in four different plant cover densities (w/out, 16, 36, 46 cuttings). Half of the modules with 36 osier cuttings got additionally interspersed with reed canary grass [*Phalaris arundinacea*]. All of the modules are going to be flushed three times with 10 litres of water, containing 1 g inhouse-MP-reference-particles per 10 litres (0.5 g LDPE + 0.5 g PA; 500 600 µm). Thereby, we want to test the differences in MP retention capacity depending on different grain sizes, plant cover densities and plant morphologies. We extract MPs with sodium metatungstate (1.8 g/cm³) or sodium chloride (1.1 g/cm³) solutions and analyse MPs with differential scanning calorimetry (DSC).

The first results of this comprehensive study will be presented at the SETAC exclusively. At the same time, we want to use the poster presentation to discuss other methods besides phytoremediation to remove MPs from soils.

3.23.P-Th334 Understanding Plasticizers in German Soil

***Simon Zerulla** and Regine Nagorka, German Environment Agency, Department Water and Soil, Germany*

In the modern world plasticized PVC products can be found everywhere. Consequently, plasticizers are ubiquitous in the environment. Nowadays, the legacy plasticizers Di(2-ethylhexyl) phthalate (DEHP) and some short-chain phthalates are banned in the EU due to toxicological concerns. As a consequence, the industry underwent a shift in production towards high-molecular-weight phthalates and non-phthalates. However, there is a lack of data regarding environmental contamination, particularly in soil.

The objective of this research is to elucidate the prevalence of both, legacy and emerging plasticizers in German soil. This offers a more comprehensive understanding of the pollution than would be possible by focusing solely on phthalates, as has been the case in many previous publications. Furthermore, it will allow to monitor the potential environmental impact of substitute products, a field in which there are currently very few studies.

Samples were obtained from the German Environmental Specimen Bank (ESB), taken by its archive program since 2002 every four years from each of the three topsoil layers. The samples represent predominant ecosystems, with consideration of the varying intensity of anthropogenic influence and land use.

We present a modified approach for analyzing soil samples, which is adapted from our research group's previous work on plasticizers in different environmental samples. This is especially demanding since the purification and avoidance of contamination and high blank values represent a significant challenge due to the omnipresence of plasticizers, even in laboratory settings.

Based on the restriction and the resulting substitution of banned phthalates, it would be expected that their concentration in German soils has decreased in recent years. This could be found in previous studies by analyzing freshwater samples. However, this clear trend could not so far be confirmed in soil samples analyzed from 2002 up to 2018. Those phthalates, which have been banned in consumer products since 1999, still account for 40 to 90% of the total plasticizer contamination found in the soil samples.

Overall, the data obtained from this project may facilitate the formulation of conclusions regarding the deposition and distribution of plasticizers. Additionally, it may provide information on the efficacy of regulations, which appeared to be not fully sufficient.

3.23.P-Th335 Interactions between Microplastics, Heavy Metal Pollution and Antibiotic Resistant *Pseudomonas aeruginosa* in Sewage Sludge: Impacts on the Safety of Agricultural Soils

Bence Prikler, *Eurofins Analytical Services Hungary Ltd., Hungary*

Sewage sludge is a major by-product of wastewater treatment, with approximately 45 million dry tonnes produced annually worldwide from municipal wastewater treatment plants (WWTPs). Sludge from these WWTPs often contains microplastics (MPs), heavy metals, and pathogens, presenting environmental and health risks if applied as fertilizer. MPs in the sludge can act as carriers for heavy metals and encourage the colonization of antibiotic-resistant bacteria like Pseudomonas aeruginosa.

An analysis of sludge samples from eight WWTPs in Hungary, using two common analytical techniques Fourier-transform infrared spectroscopy and pyrolysis gas chromatography-mass spectrometry revealed an average MP concentration of 60.33 particles/g (dry weight) and 75.46 µg/g (dry weight) by mass. The most frequently identified polymers were polyethylene, polyester, and polypropylene, known for their high metal adsorption properties. Among the heavy metals, zinc was the most abundant, with an average concentration of 628.86 mg/kg, although all levels were within EU regulatory limits.

P. aeruginosa strains isolated from the sludge showed biofilm formation abilities, heavy metal tolerance, and antibiotic resistance, associated with specific genetic markers identified through whole-genome sequencing. These findings suggest that MPs from sludge may act as vectors for both heavy metals and antibiotic-resistant bacteria in soil, raising significant risks for agricultural and ecological health when sludge is used as fertilizer.

Disclaimer/Disclosure: This work has been supported by the project no. 2020 1.1.2 PIACI KFI 2021 00239 that has been implemented with the support provided by the Ministry of Innovation and Technology of Hungary from the National Research, Development, and Innovation Fund, financed under the PIACI KFI funding scheme, by the Ministry of Innovation and Technology within the framework of the Thematic Excellence Programme 2021, National Defense and Security sub-programme (TKP2021-NVA-22) and by the János Bolyai Research Grant of the Hungarian Academy of Sciences (BO/00236/20/4) (for E.K.). 3.23.P-Th336 Investigating the Impacts of Extended Leaching from Virgin and UV-Aged Conventional and Compostable Plastics on Freshwater Organisms: A Focus on Inorganic Additives

Stefano Carnati[1], *Gilberto Binda*[2], *Andrea Pozzi*[1], *Ula Putar*[3], *Janja Novak*[3], *Mark Starin*[3] *and Gabriela Kalcikova*[3], *(1)Department of Science and High Technology, University of Insubria, Italy, (2)Norwegian Institute for Water Research (NIVA), Norway, (3)Faculty of Chemistry and Chemical Technology, University of Ljubljana, Slovenia*

The mobility of chemicals associated with plastics, including additives and contaminants, raises serious ecological concerns for terrestrial ecosystems. Under specific conditions, particularly those enhanced by plastic aging, these chemicals can leach into the surrounding environment, leaving them increasingly exposed. Although the toxicity of individual hazardous chemicals is documented, the combined toxic effects of plastic leachates as a whole remain largely underexplored, particularly for freshwater organisms. We tackled these complexities by monitoring the leaching behavior and ecotoxicity over time of two types of virgin and UV-aged plastic fragment derived from shopping bags conventional low-density polyethylene (LDPE) and compostable polybutylene adipate terephthalate blended with thermoplastic starch (PBAT/TPS). The leaching proceeded for 11 weeks and physico-chemical parameters including pH, dissolved organic carbon, nitrogen and phosphorous species and metals were monitored as well as ecotoxicity testing with freshwater organisms *Lemna minor* and *Daphnia magna*.

Results indicate that leachates from both plastic types inhibited the growth of *Lemna minor*, whereas *Daphnia magna* was unaffected. The growth inhibition in *Lemna minor* may be related to pH changes in the medium induced by plastics. Notably, UV-aged plastics released more organic matter and metals, emphasizing the risks associated with plastic aging.

Overall, these findings highlight the importance of thoroughly examining plastic materials and their leachates to understand their ecological impacts. By expanding knowledge on plastic leachate toxicity in freshwater, this study underscores the urgent need for comprehensive data on the effects of plastic pollution across different ecosystems. Such information is crucial for advancing risk assessments and guiding safter plastic alternatives.

3.23.P-Th337 Seasonal Distribution of Small Microplastics and Microlitter Components < 100 µm in the Inlet of a Drinking Water Treatment Plant

Fabiana Corami[1], *Beatrice Rosso*[1], *Alessandro Pozzobon*[2], *Carlo Barbante*[3] *and Andrea Gambaro*[4], *(1)Institute of Polar Sciences, National Research Council (ISP-CNR), Italy, (2)ARPA Veneto, Italy, (3)DAIS, Uniiversity Ca' Foscari of Venice, Italy, (4)DAIS, University Ca' Foscari of Venice, Italy*

Microplastics and microlitter, particularly those particles < 100 µm (SMPs and MLCs, respectively), have been observed in seawater and freshwater. According to the One Health Approach and the recent decision of the EU for water for human consumption (Commission Delegated Decision (EU) 2024/1441), it is fundamental to investigate the occurrence and the transport pathways and evaluate the fate of microplastics in raw water to be treated in drinking water treatment plants (DWTPs) and intended for human consumption. This work was supported by ARPAV in the framework of the BSL 6 Project, funded by Veneto Region. An artificial channel that collects and transports the water of the Sile River, meant for human consumption to a DWTP located at Ca Solaro was monitored for a whole year. Raw water was sampled monthly in the inlet of the DWTP using a customized glass water sampler, cleaned and decontaminated before use. The collected water was then stored in decontaminated amber glass bottles and transported to the Institute of Polar Sciences of the National Research Council (CNR-ISP) laboratory, where they were stored at 4°C before the pretreatment and the analysis. A rigorous QA/QC was applied to minimize plastic contamination at any step. All the operations were performed in a clean room ISO 7, which is wholly made of stainless steel and glass, and the air filters do not present plastic polymers (plastic-free clean room). An oleoextraction, previously developed, was employed as pretreatment, and the oleoextracts were filtered on aluminum oxide filters (0.2 µm, 47 mm); a purification step was performed during the filtration to remove all the interferents for the analysis via vibrational spectroscopy. An iN10 Nicolet Micro-FTIR was employed for the identification of the particles and their simultaneous quantification (Particles Analysis). Differences in the abundance and distribution of plastic polymers, plastic additives, and other microlitter components were observed. Plastic additives can be related to the presence of plastic particles and be employed as proxies of plastic polymers. The size distribution showed that the particles were concentrated in the range 20-50 µm in length for most of the polymers and microlitter components observed, although there were some exceptions, such as the particles of polyamide 6 (or nylon, PA 6). These data are crucial for the development of corrective actions and for planning mitigation strategies for plastic pollution.

Disclaimer/Disclosure: This work was supported by ARPAV in the framework of the BSL 6 Project, funded by Veneto Region.

3.24.A Analysis and Monitoring of Per- and Polyfluoroalkyl Substances (PFAS): Challenges, Standardization and Innovative Analytical Approaches

3.24.A.T-01 Navigating the Complex Landscape of PFAS CRMs

Huiling Liu[1], *Anton Pavlov*[1], *Tamal Roy*[1], *Anggi Eka Putra*[1], *Eleni Siefke*[1], *Haakon Midttaune*[1], *David Liwara*[2] *and Ana Rita Leite Araujo*[2], *(1)Chiron, Norway, (2)The Free University of Amsterdam, Netherlands*

Per- and polyfluoroalkyl substances (PFAS) have emerged as a significant environmental concern due to their persistence and potential toxicity. Accurate and reliable analysis of PFAS necessitates the use of certified reference materials (CRMs). However, the diversity and complexity of PFAS compounds present unique challenges in developing suitable CRMs.

PFAS manufacturing processes often result in products containing a mixture of branched and linear isomers, as well as other organic impurities, water, solvent, and inorganic residues. This complex mixture can significantly impact the accuracy of PFAS quantification in environmental matrices. Contaminants can affect chromatographic and net purity, influencing analytical detector response and compromising the reliability of quantitative analysis. Additionally, different PFAS homologues and isomers may exhibit distinct environmental and toxicological properties. Therefore, reference material producers must provide a range of fully characterized reference standards and labelled internal standards.

This study focuses on the development of PFAS CRMs, including the synthesis, purification, and characterization of isomerically pure, primarily n-isomer PFAS compounds. This presentation will delve into the current state of PFAS CRM availability, limitations, and emerging approaches to address these challenges. By understanding the current landscape and future trends in PFAS CRMs, we can work

towards improving the accuracy and reliability of PFAS analysis.
Forty high-purity PFAS CRMs have been developed and validated to ensure accurate and reliable analysis. These CRMs will significantly contribute to the accurate monitoring of PFAS in environmental and biological samples.

Disclaimer/Disclosure:
We thank the EU Framework Program H2020-MSCA-ITN-2020 for the funding.

3.24.A.T-02 Quantification of Ultrashort- to Long-Chain Perfluorocarboxylic Acids in Water Samples via Static Headspace Gas Chromatography Coupled to Mass Spectrometry

*Peter Leube, **Christian Vogel** and Maren Riedel, Federal Institute for Materials Research and Testing (BAM), Germany*

Perfluorocarboxylic acids (PFCAs) are one of the most prominent and studied subgroups of per- and polyfluoroalkyl substances (PFASs), which have attracted great interest in environmental and toxicology research due to their intensive use in combination with their persistence, mobility and potential threat to ecosystems and human health.
The standard method to quantify PFCAs in water samples is reverse phase liquid chromatography or, for additional quantification of ultrashort-chain PFCAs (fluorinated carbon chain length of one or two carbon atoms) too, hydrophilic interaction liquid chromatography, in each case coupled with tandem mass spectrometry. However, there are a lot of laboratories using mass spectrometry coupled to headspace gas chromatography systems (HS-GC-MS), usually to quantify a wide range of volatile organic compounds. While PFCAs themselves are difficult to measure with HS-GC-MS in water samples, this challenge can be solved by derivatizing the acids to more volatile compounds, like esters. This approach could enable laboratories using HS-GC-MS to analyse and monitor PFCAs in environmental water samples.
By following this idea, we successfully developed a HS-GC-MS method to quantify PFCAs in ultrapure water. Trifluoric acid (TFA), perfluoropropionic acid (PFPrA), perfluorobutanoic acid (PFBA) and perfluorooctanoic acid (PFOA) served as exemplary analytes of PFCAs, which were derivatized with methanol and concentrated sulfuric acid to form methyl esters. The method was optimized by varying different preparation and measurement parameters, leading to limits of detection and quantification in the ppt-range for all four analytes. The method was then tested on various real water samples, including tap and bottled water, groundwater, landfill leachate, treated wastewater and impinger water from a sewage sludge incineration experiment. Furthermore, snow samples from different locations were analyzed too. TFA was the most frequently detected PFAA, with concentrations in the ppt and low ppb range. The detection and quantification of the remaining three PFCAs vary with the sample types and sampling location.
Our results show that HS-GC-MS is suitable, and enables laboratories with this technique to quantify PFCAs in water samples.

3.24.A.T-03 Advancing PFAS Identification: Pyrolysis-GC-HRMS Analysis of Side-Chain Fluorinated Polymers and Fluoropolymers in Consumer Products

***Racchana Ramamurthy**[1], Sebastian Sauve[2] and Jinxia Liu[3], (1)McGill University, Montreal, Canada, (2)University of Montreal, Canada, (3)McGill University, Canada*

Per- and polyfluoroalkyl substances (PFAS) have long been utilized in a wide range of consumer and industrial applications due to their unique properties. Non-polymeric PFASs with low molecular weights have been the predominant focus of research and regulatory bodies. However, polymeric PFAS comprise the bulk of PFAS products but have been little studied. Among these, side-chain fluorinated polymers (SCFPs) and fluoropolymers are extensively used due to their unique hydrophobic and oleophobic properties, yet their identification remains elusive due to their polymeric nature and lack of standardized analytical techniques.
Pyrolysis-GC coupled with high-resolution mass spectrometry (HRMS) is a novel technique that can identify bulk polymer types with minimal sample preparation. The pyrolysis step breaks down the fluoropolymer/SCFPs into its constituent monomers. The pyrolysis degradation products indirectly provide a structural elucidation of unknown polymeric PFAS compounds in the sample.
This study demonstrates the use of Py-GC-HRMS for the identification and differentiation of polymeric PFAS. Two fluorotelomer acrylate-based SCFPs (C6-SCFP and C8-SCFP) and seven fluoropolymers were evaluated as reference materials. Characteristic pyrolysis products were identified for each material, with indicator ions enabling reliable detection in consumer products. Pyrolysis at 700 °C revealed

distinctive retention times and mass spectra, allowing for the development of a comprehensive database of polymer-specific markers. These marker compounds were validated in environmental and consumer product matrices, enabling the differentiation of fluoropolymers and SCFPs. A database of retention times, accurate masses, and fragment ion patterns was established, enhancing the reliability of Py-GC-HRMS for PFAS detection.
The methodology was applied to 22 textile samples and 10 cosmetics samples, representing diverse applications of polymeric PFAS. In the textile samples, PFAS were identified in 17 cases, with SCFPs predominantly detected in high-fluorine-content materials like GORE-TEX coatings. The cosmetics analysis revealed the presence of polymeric PFAS in several formulations, indicating their widespread use in consumer products. The ability to identify and quantify these polymers underscores the sensitivity and specificity of Py-GC-HRMS, addressing a critical gap in PFAS analysis.

3.24.A.T-04 Fluorine Elemental Analysis in Complex Sample Matrices: Prospects and Challenges for PFAS Analytics

Alexander Kohrer, *Matthias Schmitt, Svenja Seiffert, Marco Biel, Pascal Stopper and Martin Wende, BASF SE, Germany*

The European Union aims to impose restrictions on the use of per- and polyfluoroalkyl substances (PFAS) across various products and processes. This ambitious proposal was put forward by Denmark, Germany, the Netherlands, Norway, and Sweden in January 2023. It is noteworthy for its unprecedented scope, encompassing over 10,000 substances. The attempt to regulate such a wide-ranging class of substances, which possess vastly different properties, presents new challenges for analytics. To effectively monitor PFAS in consumer and industrial products at trace-level concentrations, there is a need to develop suitable analytical techniques. Current methods predominantly target environmental samples, particularly aqueous matrices, and are limited to a narrow range of analytes. Sum parameters and fluorine elemental analysis are promising attempts to address some of the challenges in PFAS analytics.
This contribution aims to demonstrate the role of fluorine elemental analysis within an analytical workflow for PFAS assessment. However, performing elemental fluorine analysis of PFAS compounds presents challenges within existing workflows, particularly with respect to sample preparation and fluorine detection using atomic spectrometry. Herein, the authors will discuss the prospects and challenges of total fluorine determination as a screening tool for PFAS in complex sample matrices.
Therefore, fluorine-specific graphite furnace atomic absorption spectrometry (GF-AAS) is evaluated as a method for trace-level fluorine analytics and compared to existing technologies. To extend the diversity of sample matrices that can be analyzed, a broad range of digestion techniques, including microwave-assisted digestion, pyrohydrolytic combustion, and various peroxide fusion setups, were evaluated. By combining these sample preparation approaches with GF-AAS, a novel analytical strategy for fluorine elemental analysis is proposed.

3.24.A.T-05 PFAS Sequencing: A Series of Simple Chemical Transformations for Structure Elucidation of Unknown PFAS

Vladimir Nikiforov, *NILU, Norway*

Substances with perfluoroalkyl structural elements undergo oxidation in persulfate solution, so that perfluorinated part remains largely intact and non-perfluorinated parts get removed. The stable end-products are perfluorinated carboxylic acids (PFCA) with the same or 1-3 CF2-groups shorter chain length than in the substrate. A popular TOP assay is based on such oxidation.
We hypothesized that derivatization of a PFCA, followed by oxidation can also lead to shortening of a perfluorinated chain. The approach can serve three purposes: (i) synthesis of yet unknown shorter PFCAs from known longer ones, (ii) structure elucidation of unknown longer PFAS based on the structure of known shorter ones, (iii) conversion to derivatives with a molecular ion for sensitive measurement or structure elucidation.
There was a need in a particular PFAS, the perfluoromethoxyacetic acid (12-PFECA); we have designed and executed a series of transformations towards this target.
All reactions employed in this proof-of-concept study can be carried out on micro- or nanoscale with the standard equipment of a trace analysis lab.
Briefly, we converted acids to their methyl esters and further to the 2-aminoethylamides. The amides upon oxidation yielded shorter PFECAs, indeed. The required 12-PFECA was obtained from two precursors, 14- and 122-PFECAs, which allowed to establish its structure unequivocally. A variety of additional GC- and LC-amenable derivatives was prepared. These derivatives, unlike certain parent PFECAs, produce intense molecular ions. The newly synthesized PFECAs can be further transformed to even shorter ones, thus PFAS sequencing was successfully demonstrated.

3.24.B Analysis and Monitoring of Per- and Polyfluoroalkyl Substances (PFAS): Challenges, Standardization and Innovative Analytical Approaches

3.24.B.T-01 Environmental Fingerprints of Fluorotelomer-Based Substances by GC-Based Target, Suspect, and Non-Target Analyses Surrounding Fluorochemical-Related Industries in Korea

Sori Mok[1]*, Sunggyu Lee*[1]*, Younghun Choi*[2]*, Young Hee Kim*[3] *and Hyo-Bang Moon*[1]*, (1)Department of Marine Science and Convergence Technology, College of Science and Convergence Technology, Hanyang University, "Korea, Republic of", (2)Graduate School of FEED of Eco-Friendly Offshore Structure, Changwon National University, "Korea, Republic of", (3)Chemical Research Division, National Institute of Environmental Research (NIER), "Korea, Republic of"*

As a family of high-performance chemicals, per- and polyfluoroalkyl substances (PFASs) have been extensively used in textiles, packaging materials, and grease repellants. Neutral PFASs (n-PFASs), including fluorotelomer alcohols (FTOHs), perfluorooctane sulfonamides (FOSAs), and perfluorooctane sulfonamidoethanols (FOSEs), serve as key intermediates in the production of fluorinated polymers. These compounds, referred to as precursors, have the potential to transform into various PFASs through atmospheric oxidation and biotransformation processes. Despite increasing concerns to precursors, the environmental behavior of n-PFASs encompassing their emission, transport, and degradation remains poorly understood compared to the well-known regulated PFASs. Air, sediment, and industrial wastewater samples were collected from five fluorochemical-related industrial facilities of Korea (textile, paper mill, and semi-conductor manufacturing) in 2020. Thirteen neutral PFASs were determined in air and sediment samples using gas chromatography and tandem mass spectrometry (GC/MS/MS). Suspect and non-target analysis with a GC and time of flight mass spectrometry (GC/TOF-MS) was attempted to identify other fluorinated compounds. Suspect and non-target analyses identified and semi-quantified 11 novel and emerging fluorotelomer-based substances, including fluorotelomer iodides (FTIs) and fluorotelomer methacrylate (FTMAC). Elevated concentrations of n-PFASs were observed in air and sediment samples near industrial facilities, indicating that n-PFASs are primarily emitted into the atmosphere and subsequently subject to deposition or degradation during atmospheric transport. Matrix-dependent profiles were observed in the form of predominance of shorter- and longer-chained n-PFASs in air and sediment samples, respectively. These findings suggest that air and sediment act as mobile and secondary sources of various PFASs in the environment. Additionally, fluorinated polymer-producing and consuming facilities showed distinct emission patterns of n-PFASs, underscoring the need for tailored strategies to monitor and mitigate PFAS emissions across different industries. Our studies highlight the importance of a comprehensive approach with GC-based target, suspect, and non-target analyses to better understand the environmental fate of PFAS from potential sources and to characterize contamination profiles of PFAS in multiple environmental matrices.

Disclaimer/Disclosure: This work was supported by a grant from the National Institute of Environmental Research (NIER), funded by the Ministry of Environment (ME) of the Republic of Korea (NIER-2020-03-02-002).

3.24.B.T-02 Screening and Migration Potential of Per- and Polyfluoroalkyl Substances in End-of-Waste Plastics and Textiles

Giovanni Beggio[1]*, Ateh Ndiforngu*[1]*, Maria Cristina Lavagnolo*[1]*, Simone Marangoni*[2] *and Tiziano Bonato*[3]*, (1)Department of Civil, Environmental and Architectural Engineering, University of Padova, Italy, (2)Societ Estense Servizi Ambientali (S.E.S.A. S.p.A.), 35042, Este, Italy, (3)Department of Environmental Sciences, Informatics and Statistics (DAIS), Ca'Foscari University of Venice, Italy*

The End-of-Waste (EoW) procedure, as defined in the European Waste Framework Directive (2008/98/EC), aims to provide a legal framework for remarketing waste-derived materials. However, the establishment of EoW criteria for certain recycled goods remains under debate, largely due to the lack of scientific consensus on the risks these materials may pose to human health and ecosystems. A key concern is the potential accumulation of contaminants, such as per- and polyfluoroalkyl substances (PFASs), in recycled raw materials compared to virgin counterparts. This study focuses on recycled plastics and textiles classified as EoW in Italy, which currently lack PFASs monitoring requirements despite their widespread reintegration into the circular economy.
To address this gap, a testing framework was developed to investigate the occurrence and migration potential of PFASs in recycled plastics and textiles. More than 30 samples of plastic polymers (e.g., polypropylene, polyamide, polyoxymethylene, polycarbonate, and acrylonitrile-butadiene-styrene) and 10 samples of textiles (e.g., polyethylene and natural fiber mixtures) were sourced from post-consumer and post-industrial waste streams in Italy. These materials were cryomilled to fine powders and analyzed for over 40 PFAS compounds. Migration tests simulated potential human exposure routes, including food

intake (EU Regulation 10/2011), oral exposure (EU JRC guideline EUR 19899), and dermal exposure using artificial sweat and sebum. Experimental conditions were tailored to maximize release potential while avoiding cross-contamination.
Preliminary findings, to be discussed, aim to provide a comprehensive screening of PFAS levels in recycled materials and assess their migration potential under intended use scenarios. This research is expected to offer valuable data to inform future restrictions and refine EoW criteria, supporting a safer integration of recycled materials into the circular economy.

Disclaimer/Disclosure: This study was carried out within the MICS (Made in Italy Circular and Sustainable) Extended Partnership and received funding from Next-GenerationEU (Italian PNRR M4 C2, Invest 1.3 D.D. 1551.11-10-2022, PE00000004). The study was further funded under the National Recovery and Resilience Plan (NRRP), Mission 4 Component 2 Investment 1.4 - Call for tender No. 3138 of 16 December 2021, rectified by Decree No. 3175 of 18 December 2021 of the Italian Ministry of University and Research, funded by the European Union NextGenerationEU; Award Number: Project code CN_00000033 - SP. 7, Concession Decree No. 1034 of 17 June 2022 adopted by the Italian Ministry of University and Research, CUP- C93C22002810006, Project title National Biodiversity Future Center - NBFC

3.24.B.T-03 Semi-Quantitative Nontarget Screening – The Next Step to Characterize an AFFF Contaminated Site

Christian Zwiener, *Catharina Capitain and Melanie Schussler, Eberhard Karls University Tubingen, Environmental Analytical Chemistry, Department of Geosciences, Germany*

The analysis of PFAS in environmental samples is very challenging because of their diverse physical/chemical properties and the high number of individual PFAS compounds. Target analysis is not feasible for a comprehensive characterization as only a few PFAS can be quantified and hence the total PFAS burden is often drastically underestimated. Therefore, nontarget screening (NTS) approaches are highly attractive and provide promising results. On the other side NTS is per se not quantitative.
On an AFFF contaminated soil site due to a large fire event in 2008 we identified 124 PFAS and their transformation products from 42 subclasses at confidence levels for identification between 1 and 3. These included anionic, cationic, and zwitterionic substances with 3 to 14 perfluorinated carbon atoms. Since for a large part of the identified PFAS authentic analytical standards are missing, only 28 PFAS could be quantified based on standard calibration functions. The signal intensity of the analytes alone is completely unsuitable for quantitative estimation, as this depends significantly on the structure, functional groups, chromatography (solvent composition) and mass spectrometry conditions in the electrospray process and varies over several orders of magnitude for different analytes at comparable concentrations. We therefore developed and applied a semi-quantification method based on matrix-matched average calibration curves of suitable authentic standards taking four different functional and/or ionization groups into consideration: carboxylic acids, sulfonic acids, sulfonamides, and cationic PFAS. Matrix effects in the soil extracts on the ionization efficiency have been considered by a standard addition approach. The results reveal that semi-quantification of PFAS concentrations for specific compound classes can be achieved at a median prediction error of 2.2X, at a range between 1.3X and 5X. This showed that in the topsoil of the contamination cationic and zwitterionic PFAS dominate and that semi-quantified PFAS more than doubled the sum concentration of the quantified PFAS in soil (7.3 µg/g) and the total sum finally explains completely the extractable organic fluorine (EOF) of the contamination. In conclusion, these findings have considerable consequences for the assessment of mitigation measures and remediation approaches.

3.24.B.T-04 Assessing the Added Value of the TOP Assay and AOF in Water Management

***Elvio Amato*[1]** *and Dennis Vughs[2], (1)KWR Water Research Institute, Netherlands, (2)KWR Water Research Institute, Nieuwegein, Netherlands*

Per- and polyfluoroalkyl substances (PFAS) comprise several thousands of compounds; however, only a relatively small number of these compounds are routinely monitored. Alternative analytical methods, such as the total oxidizable precursors (TOP) assay and adsorbable organic fluorine (AOF), have been recently utilized to detect a wider range of PFAS; however, both methods have benefits and limitations.
In this study, the TOP assay and AOF were compared to conventional targeted analysis to evaluate their potential added value in water management. The comparison was based on the analysis of surface water and wastewater samples, and a mass balance analysis to determine the amount fluorine (potentially PFAS) detected by each method.
After TOP assay, 13 out of 33 samples showed an increase in ?PFCA > 50%, and 7 out of 33 and increase > 100%. For samples with relatively low contamination levels, the difference between ?PFCA before and

after oxidation resulted in negative values, likely due to analytical variability. Targeted precursors did not explain the increase in ?PFCA observed after oxidation, suggesting contributions from precursors excluded from the targeted analysis.
AOF detected the highest amount of fluorine in 15 out of 23 wastewater samples, with concentrations exceeding those measured by targeted analysis by factors ranging from approximately 2 to 100. This suggested that PFAS were potentially missed by targeted analyses, even when including the contribution of precursors detected by the TOP assay. In the remaining 8 samples, targeted analysis (including ultrashort-chain PFAS) measured the highest fluorine concentrations, likely due to poor retention of ultrashort chain PFAS by the sorbent used for the extraction of organic fluorine by the AOF method. In surface water samples, AOF concentrations were up to one order of magnitude higher than those estimated using targeted analysis in all samples except for one.
Overall, results indicated that a substantial portion of PFAS was missed by conventional targeted analysis. AOF detected the largest amounts of organic fluorine, but the gap between AOF and targeted analysis was never adequately explained by the presence of precursors. This suggested that the TOP assay maybe missing a considerable portion of organic fluorine (potentially be PFAS). Future research should focus on the identification of the organic fluorine detected by AOF and the precursors detected by the TOP assay.

3.24.P-Mo266 Monitoring PFASs and Alternatives in Seafood: Analytical Method Development and Effects of Cooking Processes

*Yeun Seo[1], Junghoan Kim[1], **Younglim Kho**[1], Eunhee Lee[2] and Hyeri Jeon[1], (1)Eulji University, "Korea, Republic of", (2)Far-East University, "Korea, Republic of"*

Per- and polyfluoroalkyl substances (PFASs) have been widely utilized in consumer goods such as food packaging and nonstick cookware coatings due to their unique physicochemical properties. However, their persistence in the environment and accumulation in food products, combined with known human toxicity, have led to increasing global restrictions on their use. In response, alternative compounds such as Gen-X (HFPO-DA) and F-53B (9Cl-PF3ONS) are being adopted. While these alternatives exhibit reduced bioaccumulation potential, emerging evidence suggests they may pose toxicological risks, highlighting the need for further monitoring and assessment.

In this study, we developed an analytical method using UPLC-MS/MS to simultaneously quantify 20 PFASs, 12 alternative compounds, and 3 metabolites in seafood. Three sample preparation techniques QuEChERS, SPE, and LLE were compared to optimize recovery efficiency and sensitivity. QuEChERS was selected for its superior absolute recovery rates (ranging from 5 133%) across most analyte groups. The developed method showed high selectivity, accuracy (72.5 114.4%), and precision (0.4 16.3%), with detection limits ranging from 0.003 to 0.157 ng/g.

The method was applied to seafood samples to assess PFASs and alternative compounds pre- and post-cooking. Raw seafood showed significant contamination with PFASs, with PFOA, br-PFOS, and L-PFOS as the most prevalent compounds. Cooking processes, such as boiling and baking, reduced PFAS concentrations to varying degrees depending on temperature, duration, and sample preparation, though not consistently across all compounds. For example, PFOS and PFBA concentrations increased 1.6 and 5 times, respectively, during baking, while boiling showed limited reduction, aligning with previous findings.

These results highlight the complexity of PFASs' behavior during cooking and underscore the need for further research to clarify the mechanisms driving concentration changes. This study provides foundational insights into PFASs and their alternatives in seafood, offering critical data to inform biomonitoring and regulatory strategies.

3.24.P-Mo284 enviPath-PFAS: A Publicly Available, Expert-Curated Database and Pathway Prediction System for Biotransformations of Precursors to Persistent Perfluorinated Alkyl Substances (PFASs)

***Stephanie Rich**[1], Christopher Higgins[2], Damian Helbling[3] and Kathrin Fenner[4], (1)University of Zurich, Switzerland, (2)Colorado School of Mines, Golden, United States, (3)Cornell University, United States, (4)University of Zurich, Swiss Federal Institute of Aquatic Science and Technology (Eawag), Switzerland*

Per- and polyfluoroalkyl substances (PFASs) are man-made industrial chemicals used in manufacturing processes and commercial products to provide resistance to heat, oil, grease, and water. Unique chemical properties of these substances make them highly persistent in the environment, especially for

perfluorinated compounds. As complex mixtures of PFASs are released into the environment, polyfluorinated precursors can transform into thousands of possible molecular structures and eventually into perfluorinated end products depending on the environmental conditions. It is important for environmental chemists to understand these complex transformation processes to identify intermediate and terminal chemical structures such that comprehensive assessments on PFAS contamination at different sites can be performed.
In this project, we address this need by collecting and disseminating PFAS transformation pathways reported in scientific literature through the publicly available biotransformation database and pathway prediction system, enviPath (envipath.org). We developed a PFAS-specific data package in enviPath that contains extensive information on biologically catalyzed PFAS transformation pathways in diverse environmental microbial communities such as in soil, sediment, surface water, and activated sludge. Each pathway in the database is annotated with experimental metadata and kinetic information (if available) that can be used to interpret the relationship between environmental conditions and observed PFAS biotransformations.
We additionally used data from our PFAS-specific package to retrain the rule-based pathway prediction models in enviPath that were previously developed using mostly non-fluorinated compounds. We show here the performance of our PFAS biotransformation pathway prediction algorithms with the likelihood that each of our studied polyfluorinated precursors will be transformed into a perfluorinated end product in a specific environment. Our database and pathway prediction system in enviPath provides scientists with one organized and easily accessible online location to conveniently characterize, predict, and understand environmental PFAS contamination. This information will be essential for future efforts to remediate PFAS contaminated sites as well as for determining the source of PFAS emissions into the environment.

3.24.P-Mo286 Detection, Quantification, and Treatment of Per- and Polyfluoroalkyl Substances (PFAS) in Groundwater (DFEAT-PFAS)

Christian Vogel[1]*, Avner Ronen*[2]*, Peter Leube*[3]*, Rachel Ben Efraim*[2]*, Oded Nir*[2]*, Mohit Chaudhary*[2]*, Mirjana Futterlieb*[4] *and Stefan Panglisch*[4]*, (1)Division 4.3, Bundesanstalt für Materialforschung und -prüfung (BAM), Germany, (2)Ben Gurion University of the Negev, Israel, (3)Bundesanstalt fur Materialforschung und -prufung (BAM), Germany, (4)University of Duisburg-Essen, Germany*

Per- and polyfluoroalkyl substances (PFAS) are a large group of chemicals used in the formulations of thousands of consumer goods. Because of the recent regulations and restrictions on the use of long chain (?C8) PFAS a significant shift in the industry towards short (C4-C7) and ultrashort (C1-C3) chain alternatives has been recognized in the last years. Due to the high polarity and water solubility of ultrashort PFAS, the potential for bioaccumulation is low. However, the high persistence of ultrashort-chain PFAS will result in environmental accumulation, especially in aquatic environments, leading to potential risks for aquatic organisms and increased human external exposure through drinking water. Ultrashort PFAS like trifluoroacetic acid (TFA) are low to moderately toxic to a range of organisms. In the project we are focusing on detecting and removing PFAS, especially ultrashort-chain PFAS from contaminated groundwater. Therefore, we suggest developing and optimizing short- and ultrashort-chain PFAS detection, quantification, and removal. We will design passive sampling devices, which can collect and monitor the temporal profile of PFAS species in groundwater. This will allow us to analyze PFAS contaminations in German and Israeli groundwater using state-of-the-art novel analytical techniques. In addition, contaminated groundwater will be treated via a two-stage process, designed to concentrate the relatively low PFAS concentrations by novel membrane processes including closed-circuit reverse osmosis (CCRO) and mixed matrix composite nanofiltration membranes (MMCM). Afterwards the rejected streams, containing higher concentrations of PFAS will be treated by coagulation and the remaining PFAS adsorbed onto carbonaceous nanomaterials (CNMs).

3.24.P Analysis and Monitoring of Per- and Polyfluoroalkyl Substances (PFAS): Challenges, Standardization and Innovative Analytical Approaches

3.24.P-Mo266 Monitoring PFASs and Alternatives in Seafood: Analytical Method Development and Effects of Cooking Processes

Yeun Seo[1]*, Junghoan Kim*[1]*, **Younglim Kho***[1]*, EUNHEE LEE*[2] *and Hyeri Jeon*[1]*, (1)Eulji University, "Korea, Republic of", (2)Far-East University, "Korea, Republic of"*

Per-and polyfluoroalkyl substances (PFASs) have been widely utilized in consumer goods such as food packaging and nonstick cookware coatings due to their unique physicochemical properties. However, their persistence in the environment and accumulation in food products, combined with known human toxicity, have led to increasing global restrictions on their use. This study provides foundational insights into PFASs and their alternatives in seafood, offering critical data to inform biomonitoring and regulatory strategies.

3.24.P-Mo267 Identification of Neutral Fluorotelomer Substances in Sediment Using Gas Chromatography-Atmospheric Pressure Chemical Ionization-Ion Mobility-Mass Spectrometry

Xiaodi Shi[1]*, Haakon Austad Langberg*[2]*, Anna Sobek*[3] *and Jonathan P. Benskin*[4]*, (1)Stockholm University, Stockholm, Sweden, (2)Norwegian Geotechnical Institute (NGI), Norway, (3)Environmental Science, Stockholm University, Sweden, (4)Stockholm University, Sweden*

Despite their large number and broad structural diversity, most research on per- and polyfluoroalkyl substances (PFAS) has focused on a limited suite of polar substances. PFAS that are neutral and (semi-)volatile, in comparison, have received relatively little attention, possibly due to a lack of suitable analytical methods. In the present work, we applied a newly developed method based on gas chromatography-atmospheric pressure chemical ionization-ion mobility-high resolution mass spectrometry for identification of neutral/semi-volatile PFAS in sediments from the Baltic, a Norwegian lake, and the high Arctic. Using a collision cross section (CCS)- and mass-based filtration (i.e., <100 Å2 + 20% mass) which takes advantage of the small molecular size of fluorinated substances, we prioritized 34 unknown features in Norwegian lake sediments for further inspection. After scrutiny of in-source fragments and acquisition of reference standards, a series of novel neutral fluorotelomer thiols, disulfides, and alkyl sulfones in sediment were identified at Confidence Level 1-2 for the first time along with their CCS values. The sum semi-quantified concentration of neutral fluorotelomer substances in the Norwegian lake sediment was 96.1 ng g-1 dwt (three times higher than the total concentration of fluorotelomer sulfonates reported previously), with 88.3% attributed to fluorotelomer disulfides. The occurrence of these compounds was further validated in a NIST standard reference marine sediment, as well as in surface sediment from the Baltic Sea and the high Arctic. Only 12:2 fluorotelomer thiol and 8:2/8:2 fluorotelomer disulfide were detected in the Baltic Sea sediment, while fluorotelomer methyl sulfones appeared in almost all samples. Notably, 8:2 fluorotelomer methyl sulfone was detected in one of the Arctic sediment samples, underscoring the widespread environmental distribution and persistence of these substances. This study not only introduces a promising techinque for screening neutral and (semi-)volatile PFAS, but reports the identities and CCS values of a group of widespread neutral fluorotelomer substances for further investigation of their sources and health effects.

3.24.P-Mo268 Exploring the Detection Capability of PFAS Using High-Resolution Mass Spectrometry

Juan Francisco Ayala Cabrera[1]*, Belen Gonzalez-Gaya*[1]*, Anne San Roman*[2]*, Amaia Irizar*[3]*, Eunate Abilleira*[4] *and Nestor Etxebarria*[1]*, (1)Plentzia Marine Station, University of the Basque Country, Spain, (2)Department of Analytical Chemistry, University of the Basque Country (UPV/EHU), Spain, (3)Department of Preventive Medicine and Public Health, University of the Basque Country, Spain, (4)Ministry of Health of the Basque Government, Public Health Laboratory, Spain*

Per- and polyfluoroalkyl substances (PFAS) consist of a large group of compounds covering a vast variety

of chemical structures from ionic to neutral PFAS. These compounds have been classified as contaminants of emerging concern due to their widespread distribution and hazardous effects. PFAS are usually analyzed by liquid chromatography coupled to high-resolution mass spectrometry (LC-HRMS) using electrospray ionization (ESI) for both targeted and non-targeted screening (NTS) approaches. However, there is still a need to upgrade of analytical strategies to achieve a wide-scope determination of PFAS (including both ionic and neutrals) and enhance the detection capability of LC-HRMS methodologies. Thus, this work aims to explore mobile phase additives and acquisition methodologies to extend and enhance the PFAS coverage combining atmospheric pressure ionization sources such as ESI, atmospheric pressure chemical ionization (APCI) and photoionization (APPI).
First of all, the influence of the organic modifier (acetonitrile or methanol) as well as different mobile phase additives to enhance specific ionization mechanisms (i.e., electron capture, adduct formation, deprotonation) were evaluated for each ionization source. For instance, the ionization of PFAS by ESI was evaluated using not only conventional additives such as ammonium acetate or ammonia, but also novel additives which have shown to significantly amplify analyte signal, such as ammonium fluoride. Under the most suitable mobile phase conditions for each ionization technique, different acquisition modes involving both full scan and tandem mass espectrometry experiments consisting of data-dependent (ddMS2), variable data-independent (vDIA) or all ion fragmentation (AIF) acquisition were compared. To do so, figures of merit for were determined for the validation of the multi-target workflow according to the C/2024/5414 guidelines of the European Comission whereas other parameters such as limits of identification, type I and type II errors were established for the validation of the non-targeted workflow.

Disclaimer/Disclosure: The authors thank European Commission through the project MS4PFAS (101108881) as well as the Basque Government through Consolidated Research Group Grant (IT1446-22). ASR thanks the Basque Government for the Predoctoral Grant and JFAC acknowledges the European Union(EU) for his Marie Curie postdoctoral fellowship. BGG acknowledges an IkerBasque Fellow tenure track.

3.24.P-Mo269 A Novel PFAS Workflow for Comprehensive Analysis and Fingerprinting of Contaminated Areas

***Jan Jordens*[1]*, Emeline Hanozin*[1]*, Aline Reis de Carvalho*[1]*, Griet Jacobs*[1]*, Griet Van Gestel*[2]*, Laetitia Six*[2] *and Stefan Voorspoels*[1]*, (1)VITO, Belgium, (2)OVAM, Belgium*

PFAS are a widespread environmental problem, with increasing sources of contamination and more regions being affected. This leads to a growing number of samples that need to be analyzed, but this is limited to a subset of known PFAS compounds using a targeted approach. We propose a new PFAS analysis workflow that enables a smart selection of samples for increasingly detailed analysis, demonstrated with an example of soil samples.
When mapping PFAS contamination at a site, soil or other matrices must be collected at multiple locations, depths, and potentially at different time points. This results in an expanding sample set, but not all are necessary for obtaining a comprehensive view of contamination. Soil (or other) samples are screened using ambient ionization (DART) by picking up the soil with a glass capillary and analyzing it directly by holding it in the DART source. Mass spectra are then processed with data treatment methods such as mass defect filtering and peak identification using an in-house database. This initial screening enables rapid classification of soil samples into high, medium, or low PFAS content groups and provides insight into the types of PFAS present, distinguishing between different contamination patterns.
Based on this screening, selected samples are extracted and analyzed with a targeted LC-MS/MS method to quantify up to 92 specific PFAS compounds. The DART results hereby guide the required sample dilution for accurate analysis. To obtain a broader understanding of PFAS contamination, two additional approaches are applied. First, samples are analyzed for total organic fluorine (EOF or AOF) to assess the overall PFAS content. Secondly, the TOP assay is used to indicate the presence of precursor compounds that can degrade into target PFAS.
By comparing the DART results with targeted quantification, EOF, and TOP assay data, the next steps in the analysis are determined. If necessary, samples can be selected for in-depth non-target analysis, which provides more detailed information about PFAS precursors, degradation products, and other PFAS compounds not included in the targeted list.
This workflow provides a detailed and flexible approach to PFAS analysis, allowing for an efficient yet comprehensive evaluation of contamination at a site. By making smart preliminary sample selections, it

enables the identification of key contamination patterns, correlations, and predictions, ultimately improving our understanding of PFAS dynamics.

3.24.P-Mo270 Enhancing Per- and Polyfluoroalkyl Substance (PFAS) Analysis Efficiency in Solid and Liquid Matrices Using Automated Online SPE and LC-MS/MS

Lilit Ispiryan[1]*, Tobias Uber*[2] *and Andreas Bruchmann*[2]*, (1)Applications Development, Trajan Scientific and Medical, Australia, (2)Trajan Scientific and Medical, Axel Semrau GmbH, Germany*

The environmental impact of per- and polyfluoroalkyl substances (PFAS) remains a pressing issue due to their persistence, bioaccumulation, and associated health risks. Efficient and accurate analysis of PFAS is crucial for regulatory development work and environmental protection. Given the widespread concern and focus on PFAS, precise measurement in environmental, biological, and food samples is essential for accurate exposure assessment, risk evaluation, and understanding their fate.

The gold standard for many PFAS analytes is liquid chromatography coupled to triple quadrupole mass spectrometry (LC-MS/MS). Sample preparation is essential to achieve ever-decreasing target limits of quantification (LOQs), but these techniques can be quite tedious and time-consuming. Automation of analytical workflows is key to enhancing efficiency and sustainable practices, eliminating human error, and reducing potential contamination during sample handling.

This study demonstrates a fully automated analytical approach for solid and liquid environmental matrices. The workflow comprises solid-liquid extraction, dispersive carbon clean-up and online SPE. A modular robotic sample handling system, is directly linked to the online SPE LC-MS/MS analytical system. The entire workflow is specifically designed and tailored for the analysis of PFAS, ensuring no background contribution from the analytical system. Liquid samples or extracts are automatically injected into a miniaturized online SPE system with an integrated cartridge handling system, directly coupled to the LC-MS/MS system. The methodology encompasses over 40 analytes, following analytical procedures described in US EPA method 1633 and complies with European/ German standard methods DIN 38407-42 DIN and EN 17892:2024.

The implementation of this fully automated analytical method for PFAS analysis in environmental samples significantly enhances laboratory efficiency and accuracy. By reducing human error and contamination risks, this approach ensures more reliable data for regulatory compliance and environmental protection. Our findings underscore the importance of automation in advancing analytical chemistry, promoting greener and more efficient practices in routine laboratories.

3.24.P-Mo271 Quantification and Identification of PFAS substances in Dilute Solutions by 19F-NMR Spectroscopy

Tassilo Gruen, Martina Augustini and ***David Schaffert****, BASF SE, Analytical and Material Science, Germany*

We herein present and outline a set of methodology to identify and quantify (poly)-fluorinated organic compounds down to very low limits of detection by 19F-NMR spectroscopy. 19F-NMR spectroscopy has recently emerged as a versatile tool for screening and identification of fluorinated compounds for pharmaceutical R&D and for environmental analytics.

Since the spectroscopic properties of 19F are very similar to that of 1H in many regards, 19F-NMR can be applied at most modern high-field NMR-systems in a routine without the need for a special technical setup. However, to achieve very high sensitivity in order to detect sub-ppm concentrations in dilute solutions, cryo probes are necessary. We report our method development for a 700 MHz Avance IIIHD spectrometer equipped with a 5 mm TCI-cryoprobe, showcasing limits of detection for C-F3 containing compounds of about 25 ppb for certain applications. Excellent spectral resolution allows the identification of a series of small organic molecules as a fingerprint of their 19F chemical shift, based on database evaluation. Further, the spectral resolution also allows for a targeted quantification of different F containing compounds even in mixtures and formulations.

We highlight the applicability of this approach in close collaboration with other analytical methods and outline a strategy to gain analytical insights into challenging sample matrices.

3.24.P-Mo272 PFOA Sensor

Ambika Selvaraj[1] *and Venkateshwaran Gopal*[2]*, (1)Faculty, Department of Civil Engineering, Indian Institute of Technology Hyderabad, Adjunct Faculty, Department of Climate Change, Indian Institute of Technology Hyderabad, Adjunct Faculty, Greenko School of Sustainability, Indian Institute of Technology, India, (2)Department of Civil Engineering, Indian Institute of Technology Hyderabad, India*

PFAS, or per- and polyfluoroalkyl substances, are man-made chemicals with a unique structure featuring a hydrophobic fluorinated carbon chain linked to a hydrophilic functional group. This structural peculiarity grants PFAS compounds both hydrophobic and oleophobic properties, making them valuable in various industrial and household applications. However, the robust C-F covalent bond in PFAS leads to their persistence in the environment, earning them the moniker "forever chemicals."

Among PFAS compounds, PFOA stands out globally due to its extensive use and remarkable environmental persistence, with an estimated half-life of around 40 years. This longevity allows PFOA to accumulate in organisms, posing significant health risks such as immunotoxicity and carcinogenicity. PFOA also remains a stable byproduct of many precursor perfluorinated compounds, necessitating the development of analytical techniques for its detection in water sources.

The prevalent methods for detecting PFOA primarily involve chromatography techniques like high-performance liquid chromatography (HPLC) and gas chromatography (GC). In 2009, the U.S. EPA introduced a liquid chromatography-mass spectrometry method (Method 537) for PFOA detection in drinking water. While these chromatography methods offer precision, they are often cost-prohibitive and require skilled operators due to their complexity and time-consuming procedures.

To address the drawbacks of chromatography, alternative detection methods have emerged, notably colorimetric and fluorescent techniques. Colorimetric sensors are user-friendly and cost-effective, suitable for rapid on-site testing, while fluorescent sensors offer heightened sensitivity and specificity, ideal for detailed analyses and detecting low concentrations of PFOA. Consequently, this study focuses on developing a swift fluorometric approach for PFOA determination.

This study found an innovative method pertains to fluorescence detection using C-12 nanoclusters to detect PFOA. By mixing aqueous C1 and C2 precursor solutions to create C-12 nanoclusters, a strong fluorescence intensity is achieved. The presence of PFOA can quench this fluorescence, offering an efficient and economical detection method for PFOA.

Disclaimer/Disclosure: Patent: 202441077834 dated 14/10/2024 in the name of INDIAN INSTITUTE OF TECHNOLOGY HYDERABAD (Status: Applied)

3.24.P-Mo273 Ultrashort Chain and Highly Polar PFAS Analysis: Development of Methodology for the Determination of Residues in Human and Environmental Samples *Stephen Brewin, Environmental Sciences, Labcorp, Indianapolis, United Kingdom*

Per- and polyfluoroalkyl substances (PFAS) are a class of synthetic organofluorine compounds that have become a concern due to their persistence in the environment following extensive use over the last few decades. Due to their high degree of chemical stability, as well as their widespread use, PFAS now are increasingly being detected in the environment and appear to persist for extended periods of time. Furthermore, exposure to these chemicals in everyday objects, such as packaging and cookware, as well as within certain areas of industry, has led to the apparent bioaccumulation in certain areas of the population. Because of the concerns over health and environmental issues associated with PFAS, there has been a need to be able to monitor the occurrence of these materials in a range of matrix types.
Ultrashort chain PFAS analytes are small and highly polar compounds, with very short carbon chain lengths. These have become of considerable concern, alongside their longer chain counterparts. As a result, there is an increasing need to be able to quantify these materials in a range of environmental and biological samples, in order to assess the exposure of the population to these chemicals.
There are numerous approaches to analysing a range of these chemicals in a number of different matrix types, and this area of analytical chemistry is constantly evolving as new PFAS chemicals are identified and added to the list of those where methods already exist.
The work described in this poster summarises a project to develop and validate an LC-MS/MS method for the analysis of a typical suite of ultrashort chain PFAS chemicals in environmental samples (surface water) as well as in body fluids (plasma). A simple and robust method was required, that could be easily applied to routine analysis at low concentrations, using commonly available equipment and approaches. There was also a requirement to be able to add additional short chain PFAS analytes to expand the method as the need arises.
The method development work for the analysis of PFAS chemicals in the tested matrices is still ongoing and is based on common laboratory approaches, with quantitation performed by LC-MS/MS. This poster will present the work performed to date.

3.24.P-Mo274 Who Doesn't Love Dilute and Shoot? Robust Methodologies for Analyzing PFAS in Varying Matrices

***Tom Hey**, PerkinElmer, Canada*

Over the past decade, awareness and concern about per- and polyfluoroalkyl substances (PFAS) has grown and led to more in-depth analysis of these compounds and the effects that they can have on human health.

Commonly extensive cleanup and/or concentration steps are employed to meet the detection limits defined in regulated methods. We have found due to the robustness of our QSight LCMSMS source we are able to avoid SPE and utilize a much more simple approach of dilute and shoot and still meet the detection limits needed for methods such as EPA 1633.

3.24.P-Mo275 Evaluation of DESI Mounted on Q-Tof and TQ Mass Spectrometers to Image PFAS Compounds in Different Matrices

*Emmanuelle Claude[1], Alexandra Lee[1], Mujeebatu h Kadiri-Asamoa[1], Stuart Adams[1], Emrys Jones[1], Joanne Ballantyne[1], **Michael Andrew McCullagh**[2] and Russell Mortishire-Smith[1], (1)Waters Corporation, United Kingdom, (2)Waters Corporation*

Per- and polyfluoroalkyl substances (PFAS) are a well-known group of chemicals that have a variety of commercial and consumer uses. They have been found to be highly persistent and can accumulate in humans, animals and the environment. Traditional analysis of PFAS has focused on determination with LC-MS/MS, often laborious SPE techniques are required before analysis of sold matrices, such as food, plants or animal tissue to assess exposure routes. Here we propose the use of desorption electrospray ionization (DESI) combined with a Q-Tof operating in full scan and using a high-performance tandem quadrupole mass spectrometer to perform mass spectrometry imaging (MSI) experiments.

A mixture of PFAS compounds (PFAC30PAR, Wellington Laboratories) containing among others PFHxS, PFOS, PFOA, PFNA, PFDA, FBSA, 6.2FTS, PFBS, FOSA, was used to evaluate the levels of detection between different systems such multi-reflecting Q-Tof (MRT), cyclic IMS Q-Tof and tandem quadrupole mass spectrometers. The mixture was diluted in 50:50 MeOH/H2O. Lentils were grown wet cotton balls containing different concentrations of PFAS mixture and let grown with natural light for 14 days.

Samples were analyzed using a multi-reflecting Q-Tof (MRT), a Cyclic IMS Q-Tof (in TOF and IMS modes) and a TQ in negative ionisation mode.

From the DESI MRM TQ data, 1-3 transitions were set for 26 of the most important PFAS compounds to evaluate the best MRM transition for further MSI experiments. Only PFTrDS compound was not detected at the highest level. 77% of the PFAS compounds that were targeted were detected at 1-10 ng/mL.

In full scan MS, also 77% were detected at 1-10 ng/mL or lower when analysed using the Cyclic IMS vs. 61% on the MRT and identified with a mass accuracy lower than 500 ppb.

Interestingly the PFAS compounds have a much faster arrival time by ion mobility separation compared to singly charged tissue or solvent background peaks, enhancing the overall S/N.

Further experiments using the targeted MRM DESI TQ was performed where radishes were incubated in a control solution and a PFAS mixture solution at 10 ng/mL. The most efficiently ionising PFAS, and coincidentally those regulated in Europe, such as PFOS (498.9>80.2), PFOA (412.9>169), PFNA (462.9>219) and PFHxS (398.9> 80.1), were detected from the PFAS incubated radish section. The localisation of PFOS was on the outer ring of the radish whereas the other three PFAS were distributed more evenly throughout the section.

3.24.P-Mo276 Harnessing the Power of Mass Spectrometry and Automation to Reduce Sample Size, Sample Preparation Time and Increase Laboratory Efficiency

*Kari Organtini[1], Stuart Adams[2], Ken Rosnack[1], Oliver Burt[2], **Claudia Rathmann**[3] and Ian Wan[4], (1)Waters Corporation, United States, (2)Waters Corporation, United Kingdom, (3)Waters Corporation, Germany, (4)Promochrom Technologies, Richmond, BC, Canada, Canada*

US EPA Method 1633 has become the foundational method for analysis of PFAS in non-potable water matrices, soils, biosolids and tissues in the United States. The method consists of sample preparation using weak anion exchange (WAX) solid phase extraction (SPE) with graphitized carbon black (GCB) clean up. This EPA method is a performance based method allowing for changes to be made as long as data quality equivalency is demonstrated. With this method becoming very much in demand, laboratory throughput and efficiency must be considered for maximum laboratory success. Automation and instrument sensitivity are investigated as avenues to decreasing required sample size and therefore increasing

laboratory efficiency.
A highly sensitive LC-MS/MS system was utilized for this analysis, allowing for reduction in sample volume size while still achieving equivalent results and method detection limits to the method. Sample volumes tested ranged from 500 mL (the recommended volume in EPA 1633) down to 50 mL using an automated solid phase extraction (SPE) system for sample preparation of water samples to eliminate the need for human interaction during the sample preparation process. To make the sample prep aration process fully automated, a stacked dual layer cartridge containing both WAX and GCB chemistries was utilized instead of having to perform the GCB step manually.
Equivalency was established by demonstrating that all quality control guidelines were achieved including retention time stability, ion ratio stability, ongoing calibration verification, and recovery. Equivalency of the automated SPE system and stacked dual layer cartridge is also demonstrated as a complete workflow. A method detection limit study will demonstrate equal or lower MDLs using the automated, reduced sample volume approach. Additionally, a wastewater certified reference material was processed in an equivalent reduced sample volume and was within all certified levels for the 40 PFAS covered by EPA 1633.

3.24.P-Mo277 Identification and Quantification of Ultra-Short Chain and Short Chain Per and Polyfluorinated Alkyl Substances (PFAS) Using Ion Ratios With Low Mass Product Ions in a Single LC-MS/MS Run

*Stuart Adams[1], David Gordon[1], Kate Whyatt[1], Kari Organtini[2], **Claudia Rathmann**[3] and Peter Hancock[1], (1)Waters Corporation, United Kingdom, (2)Waters Corporation, United States, (3)Waters Corporation, Germany*

As the environmental impact and health hazards of legacy long chain (?C8) PFAS emerged, they started to be substituted for short (C4-C7) and ultrashort chain (?3) PFAS in manufacturing. The belief was these would have less of an impact but initial evidence suggests that there are still concerns regarding their effects. The analysis of the carboxylate PFAS with chain lengths C3-C5 can be problematic in terms of positively identifying the analyte due to the lack of a second product ion with suitable intensity to use for ion ratio calculations to meet common identification criteria, especially PFBA. The use of m/z 19 is possible and this response can be significantly improved using a modified high performance tandem quadrupole mass spectrometer.
For a number of short and ultrashort chain PFAS, predominately carboxylates with a carbon chain length of 5 or less (PFPrA, PFBA, PFPeA), there is limited product ions to use for identification purposes. Often the confirmation fragment for PFPrA and PFPeA used is m/z69 but this is not an option for PFBA. Work has been carried out on a high performance negative ion tandem quadrupole mass spectrometer to show that the detection of a fluoride ion (m/z 19) was possible, with the ion ratios measured for PFPrA, PFBA and PFPeA were 0.023, 0.027 and 0.163. Initial work demonstrated that for PFPeA using 263>19 showed a significantly higher response verse the alternative transition 263>69.

3.24.P-Mo278 Ultra-Sensitive PFAS Analysis According to EU Regulations in Drinking Water

*Arnd Ingendoh[1], **Philippe Diederich**[2], Miguel Perez[3] and Zahuindanda Aventura[4], (1)Bruker Daltonics GmbH & Co. KG, Germany, (2)Bruker Daltonics GmbH & Co. KG, Germany, (3)Bruker Espanola S.A., Spain, (4)Bruker Inc., United States*

PFAS are highly present in the public and pose a threat to mankind and nature. Manufactured since the 1940s as water and grease repellents in consumer products, they are considered forever chemicals. With their persistent, bio-accumulative, toxic (PBT) properties and ubiquitous presence in the environment and organisms, there is mounting evidence that exposure to PFAS may generate adverse health effects. EU regulations exist for the routine monitoring of certain PFAS in water and food with legal limits in sub-ppt range for the individual compound. Reaching these limits in a routine and robust manner is a challenge even for triple quadrupole systems of highest performance. Presented is a method for the routine targeted analysis by a novel, fast, robust and highly sensitive triple quadrupole which covers and exceeds the current EU regulations for reliable and confident PFAs quantification in water and food.

A standard list of 40 PFAS was used for the performance evaluation. An Elute HT UHPLC was coupled to an EVOQ DART-TQ+ (both Bruker, Bremen, Germany). The total runtime of the method incl. equilibration was 13.2 min with a gradient of 2 mM ammonium acetate in water and methanol on a Bruker Intensity Solo 2.0 100x2.0 mm column and a Restek 50x2.0 mm delay column. The TQ was operated in both polarities with source parameters and MRM transitions optimized. The scan speed was automatically calculated per compound with a minimum number of 12 spectra per peak and a dynamic window of 0.6

min per analyte.

Mobile phase compositions were optimized, different gradients and flow rate tested, and the equilibration time at the beginning of the injection to avoid accumulation. Typical LOQ reached for all PFAS were in the range of 0.1-0.5 ppt. These limits are 10x lower than those required by the EU Drinking Water Directive (EU 2020/2184). Linearities had typical values for R2 ? 0.999. The system shows a high robustness with much reduced contamination and crosstalk for multiple injections. The method represents a robust, highly sensitive and fast analysis of PFAS according to and exceeding the current EU regulations.

3.24.P-Mo279 Expanding the Analytical Toolbox for Environmental Monitoring: Volatile PFAS Analysis in Surface Water Using Triple Quadrupole GC/MS

*Anastasia Alekseyevna Andrianova[1], **Michael Rothaupt**[2], Ralph Hindle[3], Kathy Hunt[3] and Joel Ferrer[1], (1)Agilent Technologies Inc., United States, (2)Agilent Technologies Inc., Switzerland, (3)Vogon Laboratories, Canada*

Poly- and perfluoroalkyl substances (PFAS) are persistent, bioaccumulative pollutants linked to adverse environmental and human health effects, including endocrine disruption, immunosuppression, and organ toxicity. While regulatory frameworks have evolved for many PFAS compounds detected using LC/MS, methods for volatile PFAS remain underdeveloped. These chemicals, capable of volatilization and atmospheric transport, represent a unique risk due to their mobility and potential for inhalation exposure. Monitoring volatile PFAS in surface waters is essential for identifying contamination pathways and mitigating environmental risks.

This study addresses the need for sensitive, reliable methods for analyzing volatile PFAS, such as fluorotelomer alcohols (FTOHs), perfluoroalkane sulfonamides (FASAs), fluorotelomer acrylates (FTACs), fluorotelomer acetates (FTATs), perfluoroalkyl iodides (PFIs), and related compounds, using advanced triple quadrupole GC/MS technology. Leveraging an innovative second-generation high-efficiency ion source, the method achieves trace-level detection. The approach also benefits from robust chromatographic separation and precision calibration, providing high sensitivity and excellent linearity across a wide concentration range.

Surface water samples were analyzed to evaluate both contamination levels and the broader applicability of the method. Preliminary results demonstrate high sensitivity with low detection limits enabling tools for understanding the prevalence and distribution of volatile PFAS.

This work emphasizes the value of complementary GC/MS techniques alongside established LC/MS protocols and highlights the potential of GC/MS to enhance environmental monitoring frameworks, bridging gaps in volatile PFAS detection and informing regulatory advancements.

3.24.P-Mo280 Analysis of Ultra-Short PFAS using the Latest LC/TQ

***Day Powell**[1] and Marcus James Chadha, (1)United Kingdom, (2)Agilent Technologies, Inc., United Kingdom*

A poster presentation will highlight the latest analysis of Ultra-Short PFAS using LC/TQ.

The poster will focus on meeting the challenges of analysing Ultra-Short PFAS in real water matrices, including bore hole water, river water and drinking water. The compounds analysed include; TFA (Trifluoroacetic Acid), PFPrA (Perfluoropropanoic Acid), PFBA (Perfluorobutanoic Acid), DFA (Difluoroacetic Acid), PFMeS (perfluoromethanesulphonic acid), PFEtS (perfluoroethanesulphonic acid) and PFPrS (perfluoropropanesulphonic acid).

There will be information on how to address the common challenges including how to: reduce background interferences, retain these polar compounds using HILIC columns, reaching the low limits of detection required using the Agilent 6495D LC/TQ, reducing and removing suppression and enhancement of real water samples. The method highlighted will demonstrate how these challenges have been overcome and highlight real sample data, showing recovery and bias performance.

3.24.P-Mo281 Automated Workflow for PFAS Quantitation in Seafood: Enhancing Precision, Efficiency, and Compliance

*Gwen Lim[1], Aimei Zou[2] and **Marcus James Chadha**[3], (1)Switzerland, (2)Singapore, (3)Agilent Technologies, Inc., United Kingdom*

Per- and polyfluoroalkyl substances (PFAS) are synthetic chemicals extensively used in various industrial and consumer products due to their resistance to heat, water, and oil. These properties contribute to their persistence in the environment, where they can accumulate in aquatic ecosystems and contaminate marine

life, leading to potential human exposure through seafood consumption. The US FDA, EFSA, EURL POPs, and AOAC have established guidelines and methods to monitor and control PFAS levels in seafood to protect public health.
A primary challenge in PFAS analysis is detecting trace levels in complex food matrices like seafood. Traditional methods involving QuEChERS extraction and solid-phase extraction (SPE) cleanup are labor-intensive and prone to errors, requiring skilled analysts to ensure accuracy and reliability. This study aims to address these challenges by developing a fully automated workflow for the quantitative analysis of PFAS in seafood using the Agilent PAL3 RTC-6495D triple quadrupole LC/MS system.
The automated workflow integrates solvent extraction, QuEChERS salting-out, and µSPE cartridge cleanup, performed by the PAL3 System, with data analysis conducted on the LC/TQ system in parallel mode. This method was evaluated for its performance against various regulatory requirements, focusing on linearity, sensitivity, accuracy, repeatability, and reproducibility.
Results demonstrated excellent linearity (R^2 ? 0.99), high sensitivity with MDLs and LOQs meeting stringent regulatory criteria. The method's repeatability and reproducibility were confirmed with RSDr and RSDR values well within acceptable limits, demonstrating superior accuracy and precision across multiple PFAS analytes. The automated system significantly reduced manual intervention, minimizing human error and enhancing the precision and reliability of the analysis.
In conclusion, the fully automated workflow developed on the Agilent PAL3 RTC-6495D LC/TQ system offers a reliable, efficient, and high-throughput solution for PFAS analysis in seafood. This approach not only meets but exceeds regulatory requirements, providing a robust tool for routine laboratory operations and advancing the field of environmental and food safety analysis.

3.24.P-Mo282 Comparing Data Dependent and Data Independent Workflows for Per- and Polyfluoroalkyl Substances Analysis of NIST Interlaboratory Study Samples
*Jeremy Koelmel[1], Michael Kummer[2], Stephan Baumann[3], **Shi-Fen Xu**[4], Olivier Chevallier[3] and Krystal Pollitt[1], (1)Yale School of Public Health, United States, (2)Innovative Omics, United States, (3)Agilent Technologies, United States, (4)Agilent Technologies, Finland*
FluoroMatch Modular and FluoroMatch Visualizer are open-source tools that simplify suspect and nontarget screening of PFAS compounds. FluoroMatch Modular processes data files that have been extracted using vendor software. It uses a systematic scoring framework to communicate confidence for every feature, alongside reporting confidence levels via the Schymanski schema. IonDecon is a recent enhancement to FluoroMatch. It deconvolutes Data Independent Acquisition (DIA) All Ions data files to incorporate only those fragments correlating with precursor ions. This produces a Data Dependent Acquisition (DDA) formatted output file. We received the samples through the NIST PFAS Interlaboratory Studies and wanted to use the data to evaluate the capabilities for FluoroMatch IonDecon to process DIA file types like All Ions fragmentation. They consisted of 3 methanolic solution with sample A containing a set of PFAS standard, sample B a methanolic dilution of two aqueous film-forming foam (AFFF) commercial solutions and sample C a methanolic extract of an AFFF-impacted soil amended with an analytical standard of a single PFAS in methanol, respectively. The sample was injected four times for iterative exclusion information-data dependent analysis (iterative MS/MS). The instrument was an ultra-high-performance liquid chromatography (UHPLC) system connected to a quadrupole time-of-flight mass spectrometer (Q-TOF MS). Blanks were acquired every other injection for blank filtering. PFAS were detected in negative electrospray ionization mode. Data was acquired from m/z 100-1500, with MS/MS collision energy set to 0 and 40 eV for both AutoMS/MS (DDA) and All Ions (DIA) acquisition. Once the MS and MS/MS data had been collected, FluoroMatch Modular was used to annotate peaks extracted by MassHunter Explorer. It generates a systematic scoring framework to communicate confidence for every feature. FluoroMatch Visualizer was developed using Power BI Desktop to provide users with customizable graphs, variables, and tables to help with data interpretation. For example, new columns can be added to tables containing information of interest, new plots, and new splicers and filters can be developed. We will compare and contrast the results when processed by these two modes to determine the advantages to each mode relative to sample complexity and matrix interference in identifying the most PFAS without generating significant false positive identifications.

3.24.P-Mo283 Evaluating TD-GC-MS/MS for Measuring PFAS in Air
***Chris Llewellyn** and Hannah Calder, Markes International Ltd., United Kingdom*
Per- and polyfluoroalkyl substances (PFAS) continue to dominate environmental and public health news. As we learn more about their ubiquitous presence in every aspect of life and work analytical chemists continue to adapt monitoring techniques to new matrices and new priority species. Whilst toxicological

data on many volatile PFAS is limited they are able to transform into compounds with known adverse health effects such as perfluorocarboxylic acids (PFCAs) making robust monitoring a priority.
Volatile PFAS is a broad term covering many species, from fluorotelomer alcohols (FTOHs) to freons; this can mean extra cost for labs when trying to target different compound classes. Each compound class can have different sources and reasons for requiring monitoring: understanding emissions, consumer product testing, atmospheric monitoring, indoor air quality, vapour intrusion, occupational health monitoring and ensuring PFAS destruction. These multitude of different sample types can also pose a barrier to broadening research or offering more services if a technique cannot easily be applied to other matrices. Beyond the practicalities of sampling, concentration ranges for PFAS in different sample types can vary hugely.
TD-GC-MS/MS offers a flexible approach to sampling different matrices and analysing multiple target species whilst negating the influence of background. With accessories for collecting samples from air, materials, and industrial sources the technique offers a powerful, practical solution to monitoring PFAS from multiple sample types.
In this presentation data will be presented on the performance of the technique overall including detection limits, robustness and repeatability. Analysis of real samples will show how multiple sources can be monitored.

3.24.P-Mo284 enviPath-PFAS: A Publicly Available, Expert-Curated Database and Pathway Prediction System for Biotransformations of Precursors to Persistent Perfluorinated Alkyl Substances (PFASs)
Stephanie Rich[1]*, Christopher Higgins*[2]*, Damian Helbling*[3] *and Kathrin Fenner*[4]*, (1)University of Zurich, Switzerland, (2)Colorado School of Mines, Golden, United States, (3)Cornell University, United States, (4)University of Zurich, Swiss Federal Institute of Aquatic Science and Technology (Eawag), Switzerland*
Per- and polyfluoroalkyl substances (PFASs) are man-made industrial chemicals used in manufacturing processes and commercial products to provide resistance to heat, oil, grease, and water. Unique chemical properties of these substances make them highly persistent in the environment, especially for perfluorinated compounds. As complex mixtures of PFASs are released into the environment, polyfluorinated precursors can transform into thousands of possible molecular structures and eventually into perfluorinated end products depending on the environmental conditions. It is important for environmental chemists to understand these complex transformation processes to identify intermediate and terminal chemical structures such that comprehensive assessments on PFAS contamination at different sites can be performed.
In this project, we address this need by collecting and disseminating PFAS transformation pathways reported in scientific literature through the publicly available biotransformation database and pathway prediction system, enviPath (envipath.org). We developed a PFAS-specific data package in enviPath that contains extensive information on biologically catalyzed PFAS transformation pathways in diverse environmental microbial communities such as in soil, sediment, surface water, and activated sludge. Each pathway in the database is annotated with experimental metadata and kinetic information (if available) that can be used to interpret the relationship between environmental conditions and observed PFAS biotransformations.
We additionally used data from our PFAS-specific package to retrain the rule-based pathway prediction models in enviPath that were previously developed using mostly non-fluorinated compounds. We show here the performance of our PFAS biotransformation pathway prediction algorithms with the likelihood that each of our studied polyfluorinated precursors will be transformed into a perfluorinated end product in a specific environment. Our database and pathway prediction system in enviPath provides scientists with one organized and easily accessible online location to conveniently characterize, predict, and understand environmental PFAS contamination. This information will be essential for future efforts to remediate PFAS contaminated sites as well as for determining the source of PFAS emissions into the environment.

3.24.P-Mo285 Per- and Polyfluoroalkyl Substances (PFAS) in Ski Waxes and Snow from Cross-Country Skiing in Germany - Comparative Study of Target Analysis and Sum Parameters
Christian Vogel[1]*, Philipp Roesch*[2]*, Philipp Wittwer*[2]*, Thomas Sommerfeld*[3]*, Maren Riedel*[3]*, Peter Leube*[3]*, Ute Kalbe*[3]*, Ute Schoknecht*[3] *and Franz-Georg Simon*[4]*, (1)Division 4.3, Bundesanstalt für Materialforschung und -prüfung (BAM), Germany, (2)Bundesanstalt für Materialforschung und -prüfung (BAM), Germany, (3)Bundesanstalt fur Materialforschung und -prufung (BAM), Germany, (4)Division 4.3 Contaminant Transfer and Environment Technologies, Bundesanstalt für Materialforschung und -prüfung (BAM), Germany*
Per- and polyfluoroalkyl substances (PFAS) can enter the environment in different ways. Possible sources

are PFAS containing consumer products. One common product that makes use of the material properties of PFAS is ski wax. Here, the PFAS ensure less frictional resistance, thus allowing for increased speed. However, people who wax their skis with these waxes could absorb PFAS in their body, which can lead to health problems in the long term. Moreover, PFAS applied in ski wax abrade onto snow during use, which contaminates the environment. In our study, we analyzed various currently available ski waxes (2020s) and ski waxes from the 1980s with PFAS target analysis and with the sum parameters extractable organically bound fluorine (EOF), hydrolysable organically bound fluorine (HOF) and total fluorine (TF). Moreover, snow samples from the long-distance cross-country ski trail Kammloipe in the Ore mountains in Germany where sampled and analyzed with PFAS target analysis and the adsorbable organically bound fluorine (AOF) sum parameter to document the entry of PFAS from ski waxes into the environment. In opposite to the ski waxes from the 1980s much more ski waxes from the 2020s contain high (total) fluorine values. The highly fluorinated ski waxes contain up to approx. 6% of fluorine. The EOF and HOF sum parameters of the ski waxes are strongly decreased in comparison to the TF values (max. approx. 1000 mg/kg = 0.1%). But even the PFAS-free labeled ski waxes have EOF/HOF values in the low mg/kg range. In the snow samples from different spots of the ski trail, both the AOF sum parameter and the PFAS target analysis identified PFAS. Moreover, on a PFAS hotspot also soil samples were analyzed, which indicates that PFAS from the ski waxes adsorb after snow melting into the soil. Thus, our results show that the use of ski waxes is a possible contribution to the environmental contamination of PFAS, which is hopefully drastically reduced with the ban on fluorinated waxes by the International Ski and Snowboard Federation (FIS).

3.24.P-Mo286 Detection, Quantification, and Treatment of Per- and Polyfluoroalkyl Substances (PFAS) in Groundwater (DFEAT-PFAS)
Christian Vogel[1], *Avner Ronen*[2], *Peter Leube*[3], *Rachel Ben Efraim*[2], *Oded Nir*[2], *Mohit Chaudhary*[2], *Mirjana Futterlieb*[4] *and Stefan Panglisch*[4], *(1)Division 4.3, Bundesanstalt für Materialforschung und -prüfung (BAM), Germany, (2)Ben Gurion University of the Negev, Israel, (3)Bundesanstalt fur Materialforschung und -prufung (BAM), Germany, (4)University of Duisburg-Essen, Germany*
Per- and polyfluoroalkyl substances (PFAS) are a large group of chemicals used in the formulations of thousands of consumer goods. Because of the recent regulations and restrictions on the use of long chain (?C8) PFAS a significant shift in the industry towards short (C4-C7) and ultrashort (C1-C3) chain alternatives has been recognized in the last years. Due to the high polarity and water solubility of ultrashort PFAS, the potential for bioaccumulation is low. However, the high persistence of ultrashort-chain PFAS will result in environmental accumulation, especially in aquatic environments, leading to potential risks for aquatic organisms and increased human external exposure through drinking water. Ultrashort PFAS like trifluoroacetic acid (TFA) are low to moderately toxic to a range of organisms. In the project we are focusing on detecting and removing PFAS, especially ultrashort-chain PFAS from contaminated groundwater. Therefore, we suggest developing and optimizing short- and ultrashort-chain PFAS detection, quantification, and removal. We will design passive sampling devices, which can collect and monitor the temporal profile of PFAS species in groundwater. This will allow us to analyze PFAS contaminations in German and Israeli groundwater using state-of-the-art novel analytical techniques. In addition, contaminated groundwater will be treated via a two-stage process, designed to concentrate the relatively low PFAS concentrations by novel membrane processes including closed-circuit reverse osmosis (CCRO) and mixed matrix composite nanofiltration membranes (MMCM). Afterwards the rejected streams, containing higher concentrations of PFAS will be treated by coagulation and the remaining PFAS adsorbed onto carbonaceous nanomaterials (CNMs).

3.24.P-Mo287 Investigating the Release and Fate of Poly- and Perfluoroalkyl Substances (PFAS) in Wastewater Treatment Works by Using Diffusive Gradient in Thin-Film (DGT) Passive Samplers
Rafael Georgiou[1], *Crispin Halsall*[2] *and Jonathan Barber*[3], *(1)Lancaster University, Lancaster, United Kingdom, (2)Lancaster University, United Kingdom, (3)Cefas, United Kingdom*
Poly- and Perfluoroalkyl Substances (PFAS) are a large group of persistent and bioaccumulative synthetic chemicals found in numerous consumer products due to their thermal and chemical stability, and water- and grease-resistant properties. Their extensive applicability, detection in many environmental media, toxicity as well as ubiquitous occurrence, has led to significant regulatory responses to manage PFAS pollution by replacing legacy PFAS with novel supposedly safer alternatives. Unsurprisingly, PFAS find their way into the environment throughout their life cycle from manufacture to waste disposal.

Undoubtedly, PFAS enter wastewater and runoff streams and eventually end up in rivers and estuaries. Wastewater treatment works (WWTWs) were widely reported to be a significant source of PFAS pollution in the wider environment. Many studies have demonstrated that wastewater effluents can introduce higher PFAS amounts in the environment than influents. However, this is not always the case and WWTWs were described as sinks or secondary sources of PFAS pollution. Moreover, PFAS sources vary spatiotemporally and hundreds of fluorinated chemicals influence WWTWs emission profiles and there are still uncertainties about how PFAS are distributed in different treatment processes. Higher effluent concentrations were suggested to occur because precursor transformations during aerobic digestion can lead to the formation of terminal PFAS. Nevertheless, more studies are required to investigate the fate of PFAS during different treatment processes.
Passive sampling methods, such as diffusive gradient in thin films (DGTs) are increasingly used in studies providing time-weighted average (TWA) concentrations of organic contaminants in a period of exposure. These tools enable more accurate measurements compared to grab sampling. Using DGT samplers provide high temporal and spatial resolution that may be achieved relatively cheaply. Organisations like the U.S. EPA and frameworks such as the EU's Water Framework Directive and the Stockholm Convention have been promoting passive sampling methods for further development in future applications, such as monitoring emerging contaminants like PFAS levels in different WWTW stages.
This study aimed to utilise DGTs to examine the occurrence and fate of legacy and novel PFAS in a UK WWTW.

3.24.P-Mo288 Analysis and Monitoring of Per- and Polyfluoroalkyl Substances (PFAS) Levels in Drinking Water: Method Validation and Application in a Real Case Study

*Anne San Roman[1], Amaia Irizar[2], **Belen Gonzalez-Gaya**[3], Juan Francisco Ayala Cabrera[3], Nestor Etxebarria[3] and Eunate Abilleira[4], (1)Institute of Health Research Biogipuzkoa, Spain, (2)Department of Preventive Medicine and Public Health, Faculty of Medicine and Nursery, University of the Basque Country (UPV/EHU), Spain, (3)Research Centre for Experimental Marine Biology and Biotechnology, University of the Basque Country (PiE-UPV/EHU), Spain, (4)Ministry of Health of the Basque Government, Public Health Laboratory, Donostia-San Sebastian, Spain*

Per- and polyfluoroalkyl substances (PFAS) are a family of industrially manufactured chemicals used worldwide in many applications, from cookware to water-repellent clothing, due to their properties. Consequently, PFAS are ubiquitously found in water resources, sediments, and sludge, with drinking water being one of the main routes of human exposure. Their C-F moiety is known as one of the strongest bonds in organic chemistry, giving PFAS their persistent behavior. As a result, some PFAS are not effectively removed in drinking water treatment plants (DWTPs) and may be present in drinking water systems. Chronic exposure to these compounds, even at trace levels, can negatively impact health, as they may act as endocrine disruptors. Accordingly, regulatory agencies have established limits for PFAS levels in tap water. In light of this, a fast and robust method is necessary for analyzing various PFAS families, with variable functional groups and analytical requirements. Therefore, a method was validated and applied to assess PFAS levels at three different water basins and in towns with individual water supply from an area with high industrial activity. Currently available analytical instrumentation, such as high-performance liquid chromatography coupled with high-resolution mass spectrometry, offers a broad scope for analyte identification, including both target and suspect analyses with high precision at trace levels. With this in mind, we validated and applied a solid-phase extraction method using Oasis HLB to measure various PFAS, including carboxylates, sulfonates, ethers, amides, and emerging species. The method's performance was tested through interlaboratory assays, yielding promising results that meet current regulatory requirements. Regarding the real case study method application, the results indicated detectable levels of PFAS at all sampling sites, as well as in DWTPs, underscoring the importance of regular studies of this nature. However, the detected concentrations were below the limits set by authorities, indicating a low risk of PFAS exposure through drinking water in the study area. Nevertheless, the estimated daily intake and hazard index calculated for some PFAS varied significantly from town to town, suggesting different exposure patterns. Similarly, it was observed that DWTPs did not adequately remove these compounds, and in some cases, levels increased after water treatment, indicating a need to review DWTP protocols.

Disclaimer/Disclosure: The authors thank European Comission through the project MS4PFAS (101108881) as well as the Basque Government through Consolidated Research Group Grant (IT1446-

22). ASR thanks the Basque Government for the Predoctoral Grant PRE_2024_2_0103 and JFAC acknowledges the European Union(EU) for his Marie Curie postdoctoral fellowship. BGG acknowledges an IkerBAsque tenure track.

3.24.P-Mo289 Declining Trends of PFASs in the Pearl River Estuary, China: Insights from Oyster-Based Biomonitoring (2015-2020)

Huizhen Li *and Jing You, Jinan University, China (Mainland)*

Due to the restrictions imposed by the Stockholm Convention on perfluorooctane sulfonic acid (PFOS) and perfluorooctanoic acid (PFOA), emerging per- and polyfluoroalkyl substances (PFASs) have been introduced globally as substitutes, while the shift patterns have been limitedly unknown. In this study, oysters were used as bio-monitors to investigate the concentration and compositional changes of PFASs in the Pearl River Estuary (PRE), China, over a period of six years from 2015 to 2020. Overall, the total concentration of PFASs in oysters from the PRE showed a sharp decrease from 2015 to 2020, indicating that these products are gradually being withdrawn from the market due to China s implementation of the Stockholm Convention. Specifically, significant reductions were observed in perfluorobutanoic acid, 1H,1H,2H, 2H-perfluorooctane sulfonic acid and 2,3,3,3-tetrafluoro-2-(heptafluoropropoxy)propanoic acid. These compounds were the dominant PFASs present in the oysters, with their concentrations decreasing from 12.5 ± 9.10 to 0.63 ± 0.25 ng/g dry wt., from 23.4 ± 35.9 to 0.11 ± 0.08 ng/g dry wt., and from 10.3 ± 3.31 ng/g dry wt. to not detected, respectively. Higher concentrations of emerging, than legacy, PFASs likely reflect their higher bioaccumulation potential and more introduction. Continued PFASs use will inevitably lead to increased environmental and human exposure if not controlled. Additionally, oysters exhibited higher PFASs loads during the wet season compared to the dry season, indicating that the unique climate and environmental factors in the PRE influenced the environmental behavior of PFASs. Our study underscores the utility of oysters as sentinels for evaluating PFASs regulation success and highlights the value of continued monitoring.

3.24.P-Mo290 Leaching of PFAS from Soil to Groundwater in the Netherlands: Potential Implications and Measures for Dutch Drinking Water

Louise M. van Mourik[1]*, Floris Naus*[1]*, Bas van der Grift*[2]*, Harm Wismans*[1]*, Johan van Leeuwen*[2] *and Arjen Wintersen*[1]*, (1)National Institute for Public Health and the Environment (RIVM), Netherlands, (2)KWR Water Research Insititute, Netherlands*

Approximately 60% of Dutch drinking water is sourced from groundwater. While it is well known that PFAS are ubiquitously present in media such as soil and water, less is known about their current spatial depth distribution and their time-dependent migration within and between these two media. Preliminary calculations suggest that a significant portion of the PFAS load resulting from historical and current deposition is present in the unsaturated zone of the subsurface. The mobile characteristics of PFAS raises the question when and to what extent this historical PFAS load might reach deeper groundwater and potentially lead to future contamination of Dutch drinking water reserves.

With this study we therefore aim to obtain insight of the distribution of PFAS loads in soil and groundwater over depth in drinking water protection areas in the Netherlands. We also aim to improve predictions of concentration variabilities in the topsoil, groundwater and raw drinking water, leaching from soil to groundwater and transport from groundwater to drinking water reserves. The third aim is to develop and evaluate realistic scenarios that take into account the costs and effectiveness of measures to reduce PFAS exposure in drinking water.

To achieve this, levels of at least 34 PFASs will be determined at various depths in soil and groundwater. Using these levels, the transport of PFAS through soil and groundwater will be modelled and its results will be extrapolated for different types of groundwater extractions. Finally, an estimation will be made of the influence of representative measures on the generic prediction of the PFAS concentration and its associated exposure. This knowledge enables governments and the drinking water sector to make better-informed decisions regarding potential measures.

3.24.P-Mo291 Monitoring of Per- and Polyfluoroalkyl Substances (PFAS) in German Wolves (*Canis lupus*)

Wibke Czekalla[1]*, Rene Lammer*[1]*, Gabor Arpad Czirjak*[2]*, Claudia A. Szentiks*[2]*,* ***Bernd Gockener***[1] *and Mark Bucking*[1]*, (1)Fraunhofer Institute for Molecular Biology and Applied Ecology (IME), Germany, (2)Leibniz Institute for Zoo and Wildlife Research (IZW), Germany*

Per- and polyfluoroalkyl substances (PFAS) are a group of organic chemicals of solely anthropogenic origin. Due to several desirable properties, they are used in many industrial and commercial applications. Because of their persistent nature, PFAS are also known as forever chemicals and once they enter the

environment they can accumulate in wildlife, especially in scavenger and predator species.
The detection of PFAS and their impact on wildlife as well as the detection of emerging emission sites still challenges researchers and government agencies. The presented study aimed to measure the PFAS burden in liver samples (n = 150) of adult wolves (*Canis lupus*) from four German federal states (Brandenburg, Saxony, Saxony-Anhalt and Lower Saxony) covering a time span of ten years (2013 to 2023) representing years of return and establishment of the species to growth of the population in these areas. To achieve this, a target method for the quantification of 30 PFAS via ultra-high-performance liquid chromatography coupled to high-resolution mass spectrometry (UHPLC-HRMS) was used.
PFAS levels above the limit of quantification (LOQ; LOQs between 0.05 and 10 µg/kg) were found in all liver samples. Total PFAS concentrations ranged from 2.1 to 363 µg/kg wet weight. The predominant substance was perfluorooctane sulfonic acid (PFOS) representing between 7% and 100% of the samples total PFAS burden, followed by medium-chain to long-chain perfluoroalkyl carboxylic acids (PFCAs from C7 to C13) and perfluoroalkyl sulfonic acids (PFSAs; C6, C7 and C10). Besides PFCAs and PFSAs, two additional PFAS (ADONA and 6:2 fluorotelomer sulfonic acid (6:2 FTS)) were detected in some samples. Over the course of ten years, no statistically relevant change in PFAS concentrations (assessed for PFOS, perfluorooctanoic acid (PFOA) and the sum of all PFAS) was observed. Furthermore, there was no difference in PFAS concentration between female and male wolves. A spatial comparison on the federal-state level showed large deviations within the four surveyed German states, but a closer look showed individual PFAS hotspots close to possible emission centers such as industrial parks and mining areas. Therefore, the results of this study show that the PFAS burden of adult wolves' liver might be indicative of the position of emerging and existing emission centers.

3.24.P-Mo292 The Role of Sea Spray Aerosols in the Atmospheric Transport of Perfluoroalkyl Acids to the Arctic

Bo Sha[1], *Matthew Salter*[2] *and Ian Cousins*[2], *(1)Environmental Science, Stockholm University, Sweden, (2)Stockholm University, Sweden*

Perfluoroalkyl acids (PFAAs) are highly persistent environmental pollutants that have become ubiquitously distributed after decades of production and use. However, some uncertainties remain regarding their long-range atmospheric transport to the Arctic. Notably, PFAAs in seawater can be effectively enriched in sea spray aerosols (SSA) and remobilized from the ocean to the atmosphere. SSA have already been shown to be an important contributor to PFAA concentrations in coastal Arctic air. A previous study from our group demonstrated significant correlations between PFAA concentrations in air samples collected at Andøya, Norway, and levels of SSA tracer ions. More recently, such correlations were also observed in ice core samples from northern Ellesmere Island, Nunavut, Canada, implying that SSA may serve as a relevant transport mechanism for PFAAs in the High Arctic.
To further improve our understanding of the role of SSA as a source of PFAAs in the Arctic, this present study collected aerosol samples from the Canadian High Arctic station of Alert, Nunavut, Canada. The station is located at the northeastern tip of the Ellesmere Island and approximately 4?km from water which is covered by sea ice for most of the year. The samples were analyzed for PFAAs and SSA tracer ions, including sodium (Na?) and magnesium ($Mg^{2?}$). Correlation analysis and air mass trajectory analysis were conducted to evaluate the contribution of SSA to atmospheric PFAA levels in the Arctic region.

3.24.P-Mo293 The INBO Fish Tissue Collection: A Historical Resource

Lies Teunen, *Emily Veltjen, Marieke Desender and Caroline Geeraerts, Research Institute for Nature and Forest, Belgium*

The Research Institute for Nature and Forest (INBO) is an independent research institute of the Flemish Government that collects valuable Natural Science objects which can be used for applied scientific biodiversity research. A selection of these objects is archived as the INBO collection for the purposes of validation and reuse. This collection is currently divided in eight subcollections according to specific research activity, workflows and research teams. The INBO Fish Tissue Collection is one of the INBO subcollections that contains frozen (-20°C) freshwater fish samples (mainly muscle tissue of European eel Anguilla anguilla) collected since 2000. For each specimen locality (X,Y coordinates and date), species, length and weight is documented. This collection contains, amongst other potential data, an enormous source of information on historical pollution. Therefore, it can be used as a screening tool for the Flemish water bodies or for temporal trend monitoring in follow-up of remediation or clean-up actions. This allows for the identification of pollution hotspots in the past and can serve as a baseline for more in depth investigation of potentially contaminated areas. Previously, the INBO Fish Tissue Collection has been successfully implemented to study PFAS in 'historical' eel samples. Subsequent time trend analysis shows decreasing trends in PFAS concentrations for multiple compounds. Furthermore, locations of high concern could be identified. In the coming years, there are plans to better integrate this collection with other data sources and ensure it adheres to the FAIR principles (Findable, Accessible, Interoperable and Reusable) by connecting it to the DiSSCo (Distributed System of Scientific Collections) (Flanders) infrastructure. The collection itself will be published on GrSciColl and the institutional website to increase visibility, while the specimen data will be published on DiSSCo. The main aim is to promote use of, and collaboration with, the INBO Fish Tissue Collection to accelerate progress in pollution research. We encourage researchers not to wait until the data is published to start a collaboration.

3.24.P-Mo294 Looking Back on PFAS Contamination in 'Historical' Eel Samples From Flanders, Belgium (2000-2008) and the Comparison to More Recent Results

***Lies Teunen**[1], Marieke Desender[1], Caroline Geeraerts[1], Geert Goemans[1], Maarten de Jonge[2], Jodie Buytaert[3], Lieven Bervoets[3], Thimo Groffen[3] and Claude Belpaire[1], (1)Research Institute for Nature and Forest, Belgium, (2)Flanders Environment Agency, Belgium, (3)University of Antwerp, Ecosphere, Belgium*

The technical progress in chemical analysis enables monitoring of the pollution load more accurately, including the group of per- and polyfluoroalkyl substances (PFAS). In order to evaluate time trends, a glimpse into the past can provide valuable information. The INBO Tissue Collection contains fish samples (mainly eel muscle), collected and preserved (-20°C) since 1994 and allows for this comparison. In the current study, eel muscle tissue samples, collected between 2000 and 2008, were selected from 28 sampling sites. In total, 42 PFAS components were analysed on these samples. In this way, the distribution and magnitude of historical contamination could be mapped, and the identification of potential hotspots in the past was made possible. The total sum of PFAS was 102 ± 74 ng/g ww and PFAS profiles were mainly dominated by PFOS, PFBS and 8:2 diPAP. A few hotspots were identified with elevated concentrations of PFOS (188 ng/g ww), PFBS (183 ng/g ww), 8:2 diPAP (209 ng/g ww) and a single high reading of 6:2 FTS (31 ng/g ww). The ecological and human health risks were estimated for the historical concentrations. At 75% of the sites, the environmental quality standard for PFOS in biota was exceeded (9.1 µg/kg ww). In addition, at 32% of the sites, an exceedance of the EFSA consumption standard was measured (sum of PFOS, PFOA, PFNA and PFHxS), corresponding to a weekly allowable amount of less than 8 g (long-term exposure). Time trend analyses revealed that nowadays average PFOS concentrations were reduced with 72%. In general also concentrations of other components such as PFBS, 6:2 FTS, PFOA and PFNA reduced. However, locations with high PFAS concentrations are still present. Besides, for some components having high historical concentrations, such as 8:2 diPAP, a time trend analysis was not feasible due to variable high detection limits. This emphasises the need to further investigate this component accurately in future monitoring, using more accurate analytical methods present to date. Overall, this study underlines the importance of performing analyses on such historical samples to identify and continue to monitor problem areas. The current study can therefore be seen as a first-line screening to identify areas that need further investigation to assess pollution issues. Finally, historical data also provides a better picture of the evolution of pollution and the efficiency of certain restrictions or treatments to reduce pollution pressure.

3.24.P-Mo295 PFAS Pollution in Fish and Water from the United Kingdom and Spain: Temporal Trends and Implications for Human Dietary Exposure

***Eva Junque**[1], Marta Llorca[2], Francesco Dondero[3], Marinella Farre[2] and Iseult Lynch[4], (1)University of Birmingham, Birmingham, United Kingdom, (2)IDAEA-CSIC, Spain, (3)Universit del Piemonte Orientale, Italy, (4)School of Geography, Earth and Environmental Sciences, University of Birmingham, United Kingdom*

Poly- and perfluoroalkyl substances (PFAS), widely used since the 1940s for their water- and oil-repellent properties, persist in the environment, accumulating in the food chain and raising health concerns. This study examines 46 PFAS in 238 fish samples from the UK and Spain, including muscle fillet and whole fish from 16 species. Complementary data on water from the UK Environment Agency (2000 2024) provide additional context. Analytical methods involved LC-HRMS for target and suspect PFAS screening.

Results show higher PFAS concentrations in Spanish fish, likely due to the semi-closed system of the Mediterranean Sea. Key findings include the presence of ultra-short-chain PFAS like TFA and TFSA in 25% of samples. While median dietary intakes of PFAS through fish consumption in the UK and Spain are below EFSA's thresholds, mean values exceed limits, highlighting health risks. Species differences suggest bioaccumulation, with fish like Coley, Sea Bass, Mackerel, and Hake posing higher risks.

Disclaimer/Disclosure: This project has received funding from the European Union's Horizon 2020 research and innovation programme via the SCENARIOS project (Grant Agreement No. 101037509), the Spanish Ministry of Science and Innovation via the IMAGE project (PID2020-116789RB-C41) and from the UK Environment Agency.

3.24.P-Mo296 Quantifying PFAS Release from Solar Panels During the Use Phase

Lars Skjolding, *Mikael Olsson, Simon Ozkan, Philipp Mayer and Anders Baun, Department of Environmental and Resource Engineering, Technical University of Denmark, Denmark*

Solar technology plays a pivotal role in the current green transition and produced >1250 TWh globally in 2022. While PFAS-free alternatives and technologies exist to ensure durability their use only made up approximately 20% of the market share in 2022. Solar panel producers widely claim PFAS free panels but apply analytical methods with detection limits ranging from 0.01-0.1 mg/kg, which is in stark contrast to current environmental quality standards (EQS) for e.g. surface waters in the sub µg/L range. Consequently, novel methods are needed for up-stream quantification of the potential release during the use phase with detection limits reflecting the current EQS.

The aim of this study was to develop a screening method utilizing wiping with a solvent for quantification of potential PFAS release during the use phase. The method was applied to eight different solar panels and the release was compared to the presence of PFAS in environmental background samples in the study area. The estimated releases were also used to calculate the contaminant mass discharge and resulting EQS for a case-study area.

All samples were measured for 20 PFAS (PFPeA, PFBS, PFHxA, PFPS, PFHpA, PFHxS, 6.2 FTS, PFOA, PFHpS, PFNA, PFOS, PFNS, PFDA, PFDS, PFUdA, PFOSA, PFDoA, PFDoDS, PFTrDA and PFTeDA). The quantification limit of the method was 0.1 ng/wipe with an average recovery of the extraction method for the tested PFAS of 91±8% using standard addition with mixed PFAS standard of 10 ng/wipe. Indoor backgrounds were below quantification limits for all PFAS analyzed. The outdoor backgrounds for natural deposition resulted in the first 2 wipes exceeding the quantification limit for all measured PFAS except PFOA and PFOSA with an average sum of the remaining PFAS of 2.3 ng/wipe. The third wipe of the outdoor environmental background resulted in none of the measured PFAS above the quantification limit. Among the tested PFAS, only PFHxA (perfluorohexanoic acid) was found above the quantification limit in 6 out of 8 solar panels. The release of PFHxA ranged from 4.3-83 ng/m2 solar panel, with a corresponding contaminant mass discharge of the case study area of 2.7 52 mg during the use phase of the solar panel. Assuming direct transport to the groundwater the resulting concentration for a total release within 1 year would be 800-1400 times lower than the current EQS of 100 ng/L.

Disclaimer/Disclosure: The work was funded by Better Energy and Kolding Municipality under the grant agreement "Method development, testing and quantification of PFAS release from solarpanels."

3.24.P-Mo297 Spatial and Seasonal Characterization of 17 PFAS in Two Different Estuarine Systems Along the Portuguese Coast

Vânia Amorim[1], *Antonio Silva Ferreira*[2], *Miguel A. Pardal*[3], *Catarina Cruzeiro*[4] *and Patricia Cardoso*[1], *(1)Interdisciplinary Centre for Marine and Environmental Research (CIIMAR/CIMAR), University of Porto, Portugal, (2)Centro de Biotecnologia e Qu mica Fina (CBQF), Laboratório Associado, Escola Superior de Biotecnologia, Universidade Católica Portuguesa, Portugal, (3)Centre for Functional Ecology (CFE), Department of Life Sciences, University of Coimbra, Portugal, (4)Faculdade de Engenharia da Universidade do Porto (FEUP), University of Porto, Portugal*

Per- and polyfluoroalkyl substances (PFAS) have been produced and used in industrial and commercial products for more than 6 decades. Attending to their chemical stability, bioaccumulation potential, high persistence in the environment and toxic effects are a topic of great concern. The main goal of this study was to do a spatial and seasonal characterisation of 17 different PFAS in estuarine waters and organisms (e.g. crustacean *Carcinus maenas*) in two Portuguese estuaries (Douro and Tagus), with a high industrial load). These two different estuaries had similar ?PFAS concentrations along the time. In general, for the Tagus estuary, winter (2.33-10.18 ng/L) and spring (4.49-8.28 ng/L) presented the highest ?PFAS concentrations compared to summer (1.93-4.17 ng/L) and autumn (0.06-1.15 ng/L), except for Trancão (Tagus) in summer with a total of 25.67 ng/L. PFOA and PFOS were the most relevant compounds in our sampling sites. For the Douro estuary, the ?PFAS concentration was similar between seasons, with values ranging from 0.98-18.68 ng/L, 3.77-25.07 ng/L, 0.90-7.51 ng/L and 4.82-12.83 ng/L observed in autumn, winter, spring and summer, respectively. The diversity of compounds found was higher in the Douro (n = 17) than in Tagus (n = 6), being the most relevant ones the PFOA, PFOS and PFBS. Regarding the biological matrices, preliminary results for the crustacean *Carcinus maenas*, for the Tagus estuary (e.g. Seixal) indicated higher PFAS levels in the autumn and summer comparatively to the remaining seasons.

A pattern can be observed between the seasons with regard to the prevalence of different PFAS. In summer, shorter-chain PFAS (PFHpA and PFOA) are the most common, while in winter, longer-chain PFAS (PFDoA, PFTrDA, PFTeDA, 9Cl PF3ONS and 11Cl-PF3OUdS) are most predominant. Despite the PFAS concentrations in surface waters were below the Environmental Quality Standards (PFOS = 36000 ng/L), it is relevant to continue to monitor the coastal areas and evaluate possible impacts in the trophic web.

Disclaimer/Disclosure: PG. Cardoso (IF/01506/2014) was supported by FCT investigator contract, subsidized by the European Social Fund and MCTES (Portuguese Ministry of Science, Technology and Higher Education), through the POPH (Human Potential Operational Program), Hugo Morais by a FCT PhD grant (SFRH/BD/139762/2018) and Vânia Amorim by a FCT PhD grant (2021.06462.BD). This research was also supported by national funds through FCT Foundation for Science and Technology within the scope of UIDB/04423/2020 and UIDP/04423/2020.

3.24.P-Mo298 Evaluating the Adsorption Performance of Activated Carbon for In-Situ Remediation at PFAS Contaminated Sites

Ariette Schierz[1]*, Jannes Beihsner*[1]*, Maria Balda*[2]*, Sampriti Chaudhuri*[1]*, Sophia Wesely*[1] *and Anett Georgi*[1]*, (1)Helmholtz Centre for Environmental Research (UFZ), Department of Technical Biogeochemistry, Germany, (2)Leipzig University of Applied Sciences (HTWK), Faculty of Civil Engineering, Germany*

Due to their extreme persistence, often combined with high aqueous mobility, per- and polyfluoroalkyl substances (PFAS) are challenging to remove from the environment. The in-situ application of (colloidal) activated carbon ((C)AC) aims at a barrier effect against the further spreading of PFAS in the aquifer. This requires high-performance activated carbon materials that ensure high retardation of PFAS at low loading on the aquifer sediment (0.1-1 wt%) and thus long lifetimes in the order of decades.
Here, we will discuss the development and testing of injectable CAC for in-situ sorption barriers. Our studies include a commercially available CAC, Intraplex® (Intrapore GmbH, Germany), and an AC at the research stage, Activated Carbon Spheres (ACS). ACS are produced by bottom-up synthesis from sucrose, a locally available, renewable raw material, using hydrothermal carbonization and subsequent activation with chemical agents or gas activation with water vapour (Balda et al. 2023). This route allows the production of high-purity spherical carbon particles with a mean diameter of around 1 µm and a microporous structure. The mean pore diameters as well as the surface chemistry of the ACS can be specifically adapted to the respective application by varying the activation parameters. In comparison, commercial CAC is typically produced by top-down synthesis using wet-grinding of granular AC produced from raw materials such as lignite or hard coal.
The study presents the optimisation of the ACS material for the adsorption of perfluorooctanoic acid (PFOA), a particularly relevant representative of the PFAS. The focus was on tailoring the pore system and the surface chemistry in order to achieve optimum adsorption performance and high ageing resistance of the material. These material properties are crucial for the application of the adsorbent in an in-situ sorption barrier. Furthermore, the retardation of various PFAS by immobilized ACS from column tests are presented. These results were used to predict the long-term performance and lifetime of in-situ barriers in contaminated aquifers.

3.24.P-Mo299 In-Depth Per- and Polyfluoroalkyl Substances (PFAS) Assessment in Marine Organisms from the Seine Estuary (France) using Suspect and Non-Target Approaches

Ninon Serre[1]*, Xenia Trier*[2]*, Junjie Zhang*[2]*, Randolph Singh*[3]*, Catherine Munschy*[1]*, Aurore Zalouk-Vergnoux*[4] *and Yann Aminot*[1]*, (1)French National Institute for Ocean Science and Technology (Ifremer), Atlantic Center, Chemical Contamination of Marine Ecosystems Unit (CCEM), France, (2)Department of Plant and Environmental Sciences, University of Copenhagen, Denmark, (3)Columbia University, Mailman School of Public Health, United States, (4)Nantes Universite, Institut des Substances et Organismes de la Mer, France*

Per- and polyfluoroalkyl substances (PFAS) are synthetic chemicals known for their unique properties, which have led to widespread environmental contamination, particularly in marine ecosystems. While some legacy PFAS have been regulated, emerging alternatives complicate contamination profiles. High-resolution mass spectrometry (HRMS), coupled with non-target and suspect screening, provides a broader perspective on PFAS contamination. However, these methods have primarily been applied to heavily contaminated sites and top predators, with limited use in lower trophic organisms. Yet, such studies are essential for detecting PFAS precursors that may undergo biotransformation at higher trophic levels.This study aims to explore the potential of non-target screening to provide a comprehensive overview of PFAS contamination, including precursors, across various trophic levels. Marine species, ranging from shellfish to fish, were collected from the Seine Estuary, English Channel, France, in 2021 and analyzed using both liquid and gas chromatography-HRMS. Composite solutions of electrochemical fluorination (ECF)-based aqueous film-forming foams (AFFFs) and telomerization (FT)-based AFFFs were used as reference materials to support detection and identification. Suspect and non-target screening was conducted using El-MAVEN and PF?Screen software. Over 50 PFAS from 21 classes were detected, including non-biotransformed precursors, some of which were identified for the first time in marine organisms, such as 6:2 fluorotelomer sulfonyl amido sulfonic acid (6:2 FTSO?AoS). Perfluoroalkyl compounds were predominantly characterized by 8 perfluorinated carbons and detected in ECF AFFFs, while polyfluoroalkyl compounds were primarily 6:2 fluorotelomer structures, which occur in FT AFFFs. Given that more than 60% of the identified PFAS are typical of AFFFs suggests that AFFFs are a major contamination pathway. Ongoing GC-HRMS analysis will complement the LC data by detecting neutral PFAS. This study provides a detailed overview of PFAS contamination in marine organisms from the Seine Estuary, revealing significant pollution with largely unregulated compounds. The combined analysis of low trophic level species and AFFF references proved effective for identifying non-biotransformed precursors. This work highlights the value of integrating LC- and GC-HRMS for comprehensive PFAS analysis and identifies key compounds for future regulatory and monitoring efforts.

3.24.P-Mo300 Assessment of PFAS Adsorption in PBAT Bio-Based Microplastics

Sonia Gaaied[1], *Leilei Zhang*[1], *Terenzio Bertuzzi*[2], *Daniel Milanese*[3], *Corrado Sciancalepore*[3], *Duccio Gallichi Nottiani*[3], *Luigi Lucini*[1] *and Nicoleta Suciu*[1], *(1)Department for Sustainable Food Process (DiSTAS), Universit Cattolica del Sacro Cuore, Italy, (2)Department of Animal Science, Food and Nutrition-DIANA, Universit Cattolica del Sacro Cuore, Italy, (3)Dipartimento di Ingegneria dei Sistemi e delle Tecnologie Industriali*

Per- and polyfluoroalkyl substances (PFAS) are a class of persistent organic pollutants that have raised significant environmental and health concerns due to their widespread contamination and resistance to degradation. Despite extensive research on their environmental presence, little is known about their interactions with bio-based microplastics which may act as vectors for PFAS transport and accumulation in terrestrial environments. Polybutylene adipate-co-terephtalate (PBAT), a biodegradable plastic, has gained attention as an environmentally friendly alternative to conventional petroleum-based plastics, especially when blended with inulin for use in packaging. This study investigates the adsorption of four PFAS (HFBA, PFOA, FOSA and PFOS) on pure and inulin-blended PBAT (100-200 µm) over 56 days. Following HPLC-MS-MS analysis, the results revealed distinct adsorption patterns for each PFAS over time. Regarding adsorption on pure PBAT, HFBA showed initial adsorption at 0.5 hours, but no further adsorption was observed until 8 hours. After that, it increased and peaked at 2 days before returning to 0% at 14 days. PFOA only exhibited adsorption at 14 days. In contrast, FOSA showed the highest adsorption, starting at 38.71% at 8 hours and reaching a maximum of 93.05% at 14 days. These findings showed that FOSA exhibits the most significant and sustained adsorption on pure PBAT or inulin-PBAT. While HFBA and PFOA show delayed and lower adsorption patterns. Overall, the study provides insights into the interactions of PFAS with PBAT bio-based microplastics and emphasises the potential of PBAT as a component of PFAS accumulation in the environment.

CUP: B43D210109900 06.

3.24.P-Mo301 Isolation of PFAS-Degrading Bacteria and Assessment of Microbial Diversity in Contaminated Soil in North Italy

Sonia Gaaied[1], *Filippo Vaccari*[1], *Gabriele Bellotti*[1], *Ghada Arbi*[1], *Antonio Masi*[2], *Ilaria Battisti*[2], *Anna Rita Trentin*[2], *Giancarlo Renella*[3], *Luigi Lucini*[1], *Nicoleta Suciu*[1] *and Edoardo Puglisi*[1], *(1)Department for Sustainable Food Process (DiSTAS), Universit Cattolica del Sacro Cuore, Italy, (2)Department of*

Agronomy, Food, Natural Resources, Animals and Environment (DAFNAE), University of Padua, Italy, (3)Department of Engineering and Architecture Parco Area delle Scienze, Italy
The increasing contamination of soil and groundwater with per- and polyfluoroalkyl substances (PFAS) presents significant environmental challenges due to their persistence, mobility, and their hazardous effects. The high C-F bond strength makes PFAS non-biodegradable in the environment, and despite some in vitro evidence, their biodegradation in the environment remains an ongoing challenge. The presented research aims to address this issue through two main objectives: (1) isolating and identifying promising PFAS-degrading microorganisms from contaminated sites, and (2) assessing the microbial diversity in PFAS in soils sampled in PFAS polluted areas of Northern Italy. The first objective involves the application of sequential enrichment approach targeting two PFAS compounds (PFOA and HFBA), followed by molecular and non-molecular microbiological techniques, to identify and characterize microbial strains with biodegradation potential. The second objective was the analysis of the microbiome of soil, water and plants sampled from heavily contaminated sites of the Veneto Region. High-throughput metabarcoding was employed to characterize microbial diversity, providing insight into the potential for PFAS bioremediation. Additionally, enzymatic activity expressed by the microbial communities were assessed to understand their role in the degradation of PFAS. This research will provide new insight into PFAS degradation and could contribute to the development of sustainable bioremediation strategies for PFAS contaminated environments.

Disclaimer/Disclosure: This research was funded by Piano Nazionale di Ripresa e Resilienza, Missione 4 Istruzione e ricerca Componente 2 Dalla ricerca all impresa, finanziato dall Unione europea NextGenerationEU; Investimento 1.5 - Avviso pubblico per la presentazione di Proposte di intervento per la creazione e il rafforzamento di "ecosistemi dell'innovazione", costruzione di "leader territoriali di R&S" Ecosistemi dell Innovazione. CUP: B43D210109900 06.

3.24.P-Mo302 Expanding the Search for PFAS in San Francisco Bay: Emerging Trends in Surface Water and Sediment

***Miguel Alexander Mendez**, Ezra L. Miller, Diana Lin and Rebecca Sutton, San Francisco Estuary Institute, Richmond, United States*
Per- and polyfluoroalkyl substances (PFAS) are a broad class of compounds that are used and found ubiquitously in consumer and industrial products. Their high persistence, bioaccumulation potential, and toxicity have increasingly raised concerns of their adverse impacts on human and ecological health. In the San Francisco Bay, a highly urbanized, enclosed estuary in California, USA, PFAS have been detected throughout the environment since monitoring began in 2006. However, early analyses generally only included 13 individual PFAS via targeted methods. Building on these previous efforts, this study examined Bay surface water and sediment with an expanded analyte list that includes 27 additional PFAS (using EPA Method 1633) as well as the total oxidizable precursors (TOP) assay, which indirectly quantifies oxidizable PFAS precursors by conversion to terminal perfluorinated carboxylates (PFCAs), to assess the level of unknown precursors not detected using traditional approaches.
Overall, individual PFAS were detected throughout the Bay, notably in sites in the southern portions of the Bay where previous high detections in the environment have been found. In particular, perfluorooctane sulfonic acid (PFOS) was predominantly found in sediment, with statistically significant declines in South Bay levels throughout four sampling efforts from 2012 to 2023. In contrast, results from the TOP assay suggested the presence of unidentified precursors in sites located throughout the Bay, not just in the southern region. Summed TOP assay concentrations were up to 8x and 20x greater in water and sediment samples, respectively, when compared to targeted analysis of the same sample. These findings indicate broad, non-targeted analyses are needed to fully understand the scope of PFAS contamination, and additional PFAS, especially known precursor compounds, should be included in risk evaluations.

3.24.P-Mo303 Estimation of Background Contamination with Per- and Polyfluorinated Substances (PFAS) in Various Environmental Matrices by Measuring Plants, Soil and Water Samples From Two National Parks in Austria

*Hannes Weinbauer[1], **Oliver Mann**[1], Romana Hornek-Gausterer[2], Werner Wruss[1] and Daniel Tomsik[1], (1)ESW Consulting Wruss ZT GmbH, Austria, (2)FH Technikum Wien, Austria*
Today we know that PFAS are found ubiquitously, due to their wide range of applications. Major sources for PFAS in the environment are the chemical industry, wastewater treatment plants (WWTP) and waste incineration facilities (WIP), firefighting foams and the agricultural application of biosolids as well as landfills and their leachates. The maximum tolerable amount of PFAS concentration in soil and water is becoming regulated in different regulations and the actual limit values will probably continue to decrease. The aim of this work was to evaluate given background contamination in different environmental

matrices, as limit values are always restricted by background concentrations. To investigate PFAS background levels in Austria several environmental samples, including water, sediment, soil and wild plants were collected in the national parks Donauauen and Neusiedlersee.
The analysis was done for the 20 PFAS regulated in the European Drinking Water Directive. Various perfluorocarboxylic acids (PFCAs), PFOS and the presence of precursors were detected in the water samples in the range of 0.2-14 ng/L at all sites. In the sediment samples PFAS could be hardly detected at concentrations above 25 ng/kg dry weight (dw). The soil samples dominantly contained PFCAs and PFOS at concentrations up to 100 ng/kg dw. Across all plant samples the short-chain PFBA showed the highest concentrations with a mean of around 1300 ng/kg dw and accounting for more than 75 % of the sum of 20 EU-PFAS. The long-chain PFOS showed a mean concentration of more than 60 ng/kg dw followed by PFHpA, PFNA and PFOA.
As expected, PFAS can be detected in every environmental matrix and accumulation is highest for short-chain PFAS, especially PFBA, in plant samples. The spot with the highest detected PFAS concentration in the water and plant samples was Strandbad Illmitz in the national park Neusiedlersee. The enhanced concentrations of PFAS at the lido clearly show the anthropogenic influence on PFAS input into the environment.
With reference to the current limit values in the Austrian regulations for drinking water (TWV 2024) and soil (BAWP 2023), the assessed background contamination in the corresponding matrices is significantly lower. Referring to the Austrian QZV Chemie for surface water, in which the good chemical status is defined, the annual average environmental quality standard for PFOS with 0.65 ng/l could even be exceeded in national parks.

3.24.P-Mo304 Validation of a Method for Assessing Per- and Polyfluoroalkyl Substances (PFAS) in Human Serum from South Florida (USA) Populations Using Online SPE-LC-MS/MS

Carolina Cuchimaque[1] *and Natalia Soares Quinete*[2], *(1)Florida International University, United States, (2)Florida International University, Miami, United States*

Per- and polyfluoroalkyl substances (PFAS) are man-made chemicals linked to health risks including cancer, and environmental persistence. Their widespread use raises concerns about human exposure, with drinking water being one of the most common routes. This study validates a method to measure PFAS in human serum using online Solid Phase Extraction combined with Liquid Chromatography-Tandem Mass Spectrometry (SPE-LC-MS/MS). The method is validated to analyze serum samples from individuals with liver cancer and matched non-cancer controls in South Florida, selected from Miami-Dade County zip codes based on liver cancer mortality counts.
The method validation involves optimizing SPE conditions, chromatographic separation, and mass spectrometry parameters to ensure sensitivity and reliability. It evaluates detection and quantification limits, sensitivity, accuracy, precision, and the effects of the serum matrix on analytical measurements. Stable isotope-labeled standards are used to mitigate matrix effects and enhance accuracy.
Serum samples for this study are provided in collaboration with a local South Florida Biospecimen Repository Facility. Cases and controls are selected based on zip code residency and matched for factors such as body mass index, age, gender, smoking history, ethnicity, and other relevant but limited health data. These samples align with previously analyzed drinking water data from the same areas conducted by our research group. This study provides insights into PFAS exposure patterns and concentrations in impacted communities. However, due to the limited cohort size, it is not intended to establish a direct correlation between PFAS exposure through drinking water and bioaccumulation in human serum. Future research investigating these correlations in further detail can benefit from these findings.

This study contributes to our understanding of PFAS in human serum by determining detection frequency and concentration ranges and examining patterns of bioaccumulation across different PFAS classes as well as short- and long-chain PFAS. These findings provide a foundation for addressing public health concerns related to PFAS exposure in South Florida populations and potential links to liver cancer.

3.24.P-Mo305 Assessment of PFAS Contamination in German Soils: Non-Target Identification, Total Oxidizable Precursor Assay and Microcosm Studies

Joel Fabregat-Palau[1], *Jonathan Zweigle*[2], *Dominik Renner*[1], *Christian Zwiener, and Peter Grathwohl*[1], *(1)University of Tuebingen, Germany, (2)University of Copenhagen, Denmark*

The Rastatt case highlights a significant instance of agricultural topsoil contamination with per- and polyfluoroalkyl substances (PFAS) in southwest Germany. This contamination originated from the

application of paper sludge in topsoil. In this study, 40 PFAS were monitored in eight topsoil samples from the Rastatt/Baden-Baden and Mannheim regions, following the EPA 1633 guidelines. In addition to targeted PFAS analysis, non-target screening was performed to identify PFAS precursors. The screening revealed phosphorus-containing PFAS precursors, including several homologues of FTMAPs and diPAPs, as well as diSAmPAP, which collectively accounted for over 80% of the total PFAS burden in the soil. Nonetheless, some overlooked precursors may still be present in some of the monitored locations.
The identification of specific PFAS intermediates, along with previous findings of perfluoroalkyl acids (PFAAs) in groundwater, suggests that biotransformation of precursors occurred in the topsoil, followed by the leaching of PFAAs into groundwater. To further investigate the factors influencing biodegradation and to estimate potential contamination time scales, the study combined chemical oxidation of precursors (TOP assay) with extractable organic fluorine (EOF) measurements to evaluate the PFAS reservoir in the soil.
Batch microcosm incubations were also conducted to monitor PFAA concentrations over time. The observed increase in PFAA concentrations was attributed to the breakdown of PFAS precursors. Based on these findings, PFAA generation rates were estimated. To better understand the variability in degradation rates across the eight different soils, the role of microbial biomass carbon and phospho(mono/di)esterase enzymatic activities was analyzed using principal component analysis (PCA). This approach explained the differences in observed rate constants.
The study also assessed contamination time scales, which indicated that the transformation of precursors and subsequent leaching of short-chain PFAS would likely persist for decades. The findings underscore the utility of combining non-target screening, TOP assay, and EOF approaches for environmental PFAS analysis. Moreover, the study provides a methodology to estimate contamination time scales in cases of mixed PFAS pollution. Our results also suggest that microbial biomass carbon and specific phospho(mono/di)esterase enzymes may play a role in PFAS biotransformation, warranting further investigation.

3.24.P-Mo306 Impacts of Sea Spray Aerosol Transport of Perfluoroalkyl Acids (PFAAs) on Coastal Regions

Theresa Doring[1]*, Bo Sha*[2]*, Matthew Salter*[3] *and Ian Cousins*[3]*, (1)Stockholm University, Sweden, (2)Environmental Science, Stockholm University, Sweden, (3)Stockholm University, Sweden*
Coastal contamination by perfluoroalkyl acids (PFAAs) has emerged as a pressing environmental and public health concern. In Denmark, elevated concentrations of PFAAs in environmental media such as groundwater, soil and vegetation have been detected on the northwest coast of Jutland despite the absence of obvious local sources. These concentrations decline sharply within a few kilometers inland, implying that the atmospheric transport of PFAAs via sea spray aerosols (SSA) from the Northern Sea may be a significant source. Previous laboratory and field studies have shown that PFAAs are strongly enriched in SSA, and large SSA particles (>10 ?m) are likely driving substantial dry deposition near coastal zones, where they pose risks to groundwater and drinking water supplies.
This project aims to unravel the processes governing inland PFAA transport and deposition from coastal areas, focusing on SSA-mediated mechanisms. We will conduct air sampling and atmospheric dry/wet deposition measurements along the Danish coast to investigate the direct evidence of SSA-driven PFAA contamination in these regions. By integrating field measurements and high-resolution numerical modeling, we will evaluate the impacts of SSA-mediated atmospheric transport of PFAA on their concentrations in coastal and inland areas.
The findings from this research will advance understanding of PFAA dispersion in coastal environments, improve predictions of contamination risks and inform regulatory and mitigation strategies. This work carries critical implications for safeguarding coastal drinking water resources and addressing the persistent global challenge of PFAS pollution.

3.24.P-Mo308 Determination of Persistent and Mobile Organic Compounds in the River–Groundwater Interface of the *Besòs* River Delta, Spain, Using a Wide Extraction Approach

Arianna Bautista[1]*, Maria Bjornsdotter*[2]*, Carmen Saez*[3]*, Anna Jurado*[3]*, Marta Llorca-Casamayor*[1]*, Estanislao Pujades*[3] *and* ***Marinella Farre***[1]*, (1)ON-HEALTH Group, Institute for Environmental Assessment and Water Research (IDAEA-CSIC), Spain, (2)ON-HEALTH Group, Institute for Environmental Assessment and Water Research (IDAEA-CSIC), Sweden, (3)Department of Geosciences, Institute of Environmental Assessment and Water Research (IDAEA-CSIC), Spain*
Climate change impacts the Mediterranean region, transforming it from region with a semi-arid climate to

a region with an arid climate. Under this situation, while groundwater is an essential hydric resource, its existence is in danger due to anthropogenic pressures. Persistent mobile organic compounds (PMOCs) have recently been recognised as an emerging problem; however, PMOCs in groundwater need to be better characterised. Here, we present a new analytical method to characterise the profile of PMOCs in groundwater based on two parallel solid-phase extraction (SPE), using weak anion exchange and weak cation exchange. Extracts were analysed by ultraperformance liquid chromatography (UPLC) using mix-mode chromatography for those compounds analysed under negative ionisation conditions and hydrophilic interaction liquid chromatography (HILIC) under positive conditions coupled to high-resolution mass-spectrometry (HRMS) using a Q-Exactive Orbitrap analyser. For the suspect screening of PMOCs in groundwater, the acquisition mode was in full scan (FS) by independent scan of all ion fragmentation. For the tentative identification, different online databases such as Environmental and Food Safety (EFS) HRAM Compound database, PFAS NIST database, ChemSpider for chemical structural information, MzCloud as a mass spectral database, and an in-house list with 1280 PMOC structures have been used. The performance of the method was assessed with 29 representative PMOCs which were selected based on the previous literature. The recovery rates have been between 63-110% for 90% of the target compounds and method limits of quantification (MLQ) between 0.3 and 10.5 ng/L.
The optimised approach was applied to assess PMOCs in the Besòs River aquifer, NE Spain, showing 148 tentatively identified structures at confidence levels 1-3. Among them, 66 suspects were tentatively identified at level 3, 54 at level 2, and 28 confirmed at level 1. Most of these compounds were polar and highly polar compounds which are difficult to retain with other extraction approaches. Major detected compounds were pharmaceuticals and personal care products (46), followed by perfluoroalkyl and polyfluoroalkyl substances (PFAS) (32), industrial additives (27), and pesticides (23), among other groups. Some compounds, such as ultrashort chain PFAS and fluorinated betaines, were detected for the first time in groundwaters in Spain.

3.24.P-Mo309 PFAS in the Air: Insights from the Belgian Frontline

Aline Reis de Carvalho, Griet Jacobs, Jelle Hofman, Jan Peters, Patrick Berghmans, Gert Otten and ***Stefan Voorspoels****, VITO, Belgium*

The PFAS crisis in Belgium, triggered by roadworks near a PFAS production plant, necessitated urgent analytical solutions. The Flemish Environmental Reference Laboratory at VITO rapidly developed advanced methods to meet this demand, going beyond state-of-the-art approaches to address diverse environmental matrices, including flue gases and ambient (outdoor) air. These efforts combined target analysis (LC-MS/MS) with non-target analysis (NTA) using high-resolution MS, expanding the detection scope to PFAS compounds, classes, and precursors.
In flue gases, a validated method (LUC/VI/003) quantified 28 PFAS compounds with measurement uncertainties below 50%. Sulfonic acids were captured early in the sampling train, while carboxylic acids and short-chain PFAS were found in downstream fractions. The method highlighted challenges, such as glassware contamination by long-chain PFAS, emphasizing the importance of rigorous cleaning protocols. For outdoor air, PFAS quantification was achieved using active (filters and PUF/XAD) and passive (deposition jars) sampling. Less volatile compounds (e.g., PFOA, PFOS) were retained in filters, while volatile compounds (e.g., MePFBSA) were captured in PUF/XAD. Initial findings revealed high levels of ultra-short-chain PFAS (e.g., TFA, PFPrA, PFPrS) in PUF/XAD, prompting ongoing validation of sampling and analytical methods. Method optimization underscored the critical role of matching mass-labeled internal standards for accurate quantification.
NTA of selected samples uncovered novel PFAS classes (e.g., H-substituted carboxylic acids) and expanded known ones (e.g., PFHpSA), with unknown compounds representing up to 50% of detected PFAS. These findings highlight NTA's value in uncovering previously unmonitored PFAS.
This work advances PFAS monitoring by providing robust methodologies tailored to diverse matrices. Sharing challenges and solutions encountered during method development fosters collaboration and enhances the scientific community s ability to respond to emerging environmental crises.

3.24.P-Mo310 Distribution and Characteristics of Per- and Polyfluoroalkyl Substances (PFASs) in Surface Waters of the Western Pacific Ocean

*Ruei-Feng Shiu[1], **MENG-DER FANG**[2], Hui-Ru Li[3] and Gwo-Ching Gong[1], (1)Institute of Marine Environment and Ecology & Center of Excellence for the Oceans, National Taiwan Ocean University, Taiwan (Greater China), (2)Green Energy and Environment Research Laboratories, Industrial Technology Research Institute, Taiwan (Greater China), (3)Institute of Marine Environment and Ecology, National Taiwan Ocean University, Taiwan (Greater China)*

Per- and polyfluoroalkyl substances (PFASs) are widespread in marine environments, posing potential ecological risks to aquatic organisms and humans. However, knowledge of their transport mechanisms and ultimate fate in open oceans remains limited. This study investigates the contamination status of PFASs in surface seawater across the western Pacific Ocean and adjacent marginal seas, including the Taiwan Strait, East China Sea, and the Kuroshio Current. Six of the eight target PFASs were detected, with total concentrations of eight PFASs (?8 PFASs) ranging from below detection limits to 5.09 ng/L. Elevated PFAS concentrations were observed in the East China Sea, with levels significantly decreasing from river mouths to offshore areas, indicating riverine input as a major source of anthropogenic pollutants. Notably, PFASs were also identified in the Kuroshio Current, suggesting contamination in its typically ultraoligotrophic and pristine waters. Across the study region, perfluorobutanesulfonic acid (PFBS), perfluorooctanoic acid (PFOA), and perfluorononanoic acid (PFNA) were the predominant PFASs. These findings provide critical insights into the distribution and behavior of PFASs in global open ocean environments.

3.24.P-Mo311 Advanced Modeling of PFAS Sorption in Soils Through Machine Learning

*Joel Fabregat-Palau[1], **Amirhossein Ershadi**[1], Michael Finkel[2], Miquel Vidal[3], Anna Rigol[3] and Peter Grathwohl[2], (1)Universty of Tuebingen, Germany, (2)University of Tuebingen, Germany, (3)University of Barcelona, Spain*

Emerging and novel per- and polyfluoroalkyl substances (PFASs) present a significant challenge due to their environmental persistence, unique physicochemical properties, and widespread use across industries. While efforts to phase out legacy PFASs progress, innovative tools are urgently needed to understand the behavior of newer compounds and inform risk management strategies. This study introduces PFASorptionML, a machine learning tool designed to predict the sorption behavior of PFASs in soils, offering insights into their environmental mobility and potential risks. Using a dataset encompassing 51 PFAS compounds across 455 soil and sediment samples, the model integrates compound-specific parameters, including molecular weight, hydrophobicity, and pKa, with soil properties like pH, organic carbon content, texture, and cation exchange capacity. For the first time, PFAS speciation is explicitly addressed in sorption predictions. The tool's sensitivity analysis reveals the dominant role of hydrophobic interactions in PFAS sorption, emphasizing the importance of compound structure in environmental behavior. Beyond accurate predictions, PFASorptionML enables the generation of high-resolution mobility maps by linking with soil data repositories, providing a valuable platform for environmental risk assessments and supporting the transition to safe and sustainable PFAS alternatives.

3.25 Emerging and Novel Per- and Polyfluoroalkyl Substances (PFASs): Latest Findings and Innovation Towards Safe and Sustainable Alternatives

3.25.T-01 Colloidal Side-Chain Fluorinated Polymer Nanoparticles are a Significant Source of PFAS Contamination in Textile Wastewater

***Lee Ferguson**[1], Patrick Faught[2], Marzieh Shojaei[1] and Abigail Joyce[1], (1)Duke University, United States, (2)Duke University, Durham, United States*

Side-chain fluorinated polymers (SCFP) based on per-and-polyfluorinated substances (PFAS) are used to create water-repellant and stain-resistant fabrics on textiles. The discovery of unexplained C4 C8 perfluorocarboxylic acids (PFCAs) at concentrations ranging from 50-1,000 ng/L in public drinking water supplies downstream from textile industry discharges in North Carolina initiated an investigation into the source of these PFAS. Analysis of raw industrial wastewaters in an upstream municipality revealed short-chain (C4-C7) PFCAs at levels insufficient to explain the extent of contamination. However, elevated concentrations of short-chain PFCAs were found in the corresponding wastewater treatment plant (WWTP) effluent relative to its influent, suggesting the presence of unknown PFAS precursors in raw wastewater. We employed the total oxidizable precursor (TOP) assay to assess PFAS precursor concentrations in textile wastewaters entering the WWTP. PFAS precursor concentrations near 10,000,000 ng/L were found in raw textile wastewaters after TOP assay, revealing the primary source of PFAS to the WWTP. A mass balance of WWTP influent and effluent revealed that over 90 percent of SCFP entering the WWTP was removed to sludge and eventual biosolids. TOP fingerprinting indicated that textile-associated precursors contained primarily 6:2 fluorotelomer-based PFAS functionality, but the application of high-resolution mass spectrometry (HR-MS) failed to yield the identity of these precursors. Ultrafiltration prior to TOP assay revealed that PFAS precursors in textile wastewater were colloidal in nature, as they passed through a 0.2 µm filter but were quantitatively retained by a 100 kDa ultrafiltration membrane. Size separation and characterization of these isolated colloidal fractions using asymmetric field-flow fractionation (AF4) revealed them to be consistent with SCFP nanoparticles used in fabric finishing. In addition to wastewaters, SCFP from WWTP biosolids were extracted by sonication in a surfactant solution and were characterized by ultrafiltration and the TOP assay. The presence of colloidal PFAS in wastewater and their potential to degrade to molecular PFAS during transport poses significant challenges for receiving waters, downstream drinking water, and areas where biosolids are applied.

3.25.T-02 Evaluating Sorptive Removal of Novel Fluorochemicals from Lithium-Ion Batteries Using Commercial Sorbents

***Faezeh Pazoki** and Jinxia Liu, McGill University, Canada*

The growing demand for lithium-ion batteries (LIBs), driven by electric vehicles and electronics, has raised concerns about their environmental impact, particularly the release of per- and polyfluoroalkyl substances (PFAS). These highly persistent and toxic compounds, used in LIB components such as electrolytes, binders, and separators, pose risks to water quality and ecological health. Although sorption technologies, including granular activated carbon (GAC), ion exchange resins (IXR), and clay-based sorbents like FluoroSorb-200, are commonly used for PFAS removal, their effectiveness for PFAS specific to LIBs has not been thoroughly evaluated. This study investigates the sorption behavior of seven lithium-based PFAS (LiBETI, LiTFSI, LiPF6, LiBF4, LiFSI, LiFTSI, and LiOTf) across deionized water, groundwater, and landfill leachates to assess sorbent performance under varying environmental conditions. Factors such as pH, ionic strength, and sorbent dosage were systematically studied to understand their influence on sorption efficiency.

Results demonstrated that all sorbents achieved high removal efficiencies (>95%) for larger PFAS, such as BETI, TFSI, FSI, and FTSI, in deionized water. For smaller PFAS, like BF4, PF6, and Triflate, IXR outperformed GAC and FluoroSorb, with BF4 removal limited to ~60%. In complex matrices such as landfill leachates, GAC exhibited poor performance across all PFAS, with removal efficiencies dropping below 20% due to fouling by organic matter and competing ions. FluoroSorb maintained stable removal in groundwater but experienced a 10 30% reduction in landfill leachates. IXR demonstrated the highest overall efficiency, though Triflate sorption decreased by ~40% in groundwater and landfill leachates, likely due to competing anions.

Characterization techniques, such as XRD, FTIR and SEM, were employed to elucidate the sorption mechanisms. Isotherm and kinetic models were applied to quantify the sorption capacity and rate. Furthermore, the long-term stability of the sorbent-PFAS complexes was assessed under various conditions.

The findings of this study will contribute to a better understanding of the sorption behavior of emerging PFAS onto commercial sorbents in complex matrices.

3.25.T-03 To Treat or Not to Treat: Comparing Health Impacts of PFAS Exposure to Health Impacts of PFAS Removal Technologies

***Sanne Julie Smith**, Mar Palmeros Parada and Emile Sylvestre, Delft University of Technology (TU Delft), Netherlands*

Associations between PFAS and adverse health effects have led to the global introduction of drinking water concentration limits in the low ng/L range. PFAS exposure has been shown to contribute considerably to disease burden, so interventions are clearly necessary to reduce exposure. However, to adequately quantify the health benefits of intensified drinking water treatment, the health effects of the treatment technologies should be considered as well. Therefore, the aim of this study was to estimate both types of human health impacts, i.e. the health gained by reduced PFAS exposure via drinking water and the health lost due to the drinking water treatment technologies, and quantify these in disability-adjusted life years (DALYs).

We performed a life cycle assessment to quantify the health lost (in DALYs) due to an increased regeneration frequency of granular activated carbon (GAC), which is used at a local drinking water producer to meet recent PFAS guidelines. To quantify the health gained by lower PFAS exposure, we first used the existing physiologically based pharmacokinetic model by EFSA to relate ?EFSA4 concentrations in drinking water to those in blood serum. Serum concentrations were then used in exposure response relationships from literature to relate them to an increase in disease occurrence, which was subsequently related to DALYs.

For all endpoints considered, we found that the gain in human health by removing PFAS from drinking water was in the same range as the loss of human health from the increased GAC regeneration. While the high uncertainty in PFAS health effects limits our ability to make a reliable comparison, it is likely that other interventions that limit PFAS exposure have a higher net benefit than drinking water treatment. For example, phasing out all non-essential uses of PFAS will lead to a decreased exposure via multiple routes, including diet. Altogether, PFAS limits in drinking water may need to be determined on a case-by-case basis, that considers the current concentration levels in addition to the secondary impact of the required treatment technologies. This study mainly serves to start a dialogue about this complex issue, which is particularly important as increasingly many PFAS are added to drinking water guidelines, most of which are even more challenging to remove than those currently included.

3.25.T-04 Unveiling PFAS in Cosmetics: Global Insights and Australian Market Analysis Using Non-Target and Suspect Screening Analysis

Sara Ghorbani Gorji*, Vivienne Noonan, Kevin Thomas and Sarit Kaserzon, Queensland Alliance for Environmental Health Sciences (QAEHS), The University of Queensland, Australia*

Per- and polyfluoroalkyl substances (PFAS) are synthetic chemicals valued for their unique physicochemical properties, making them integral to many consumer products. However, growing evidence of their toxicity, environmental persistence, and presence in cosmetics and personal care products (PCPs) has raised significant health and environmental concerns. Despite these risks, comprehensive data on PFAS prevalence in cosmetics remain sparse, leaving critical gaps in understanding consumer exposure.

The current study addresses these gaps through a twofold investigation. First, a scoping review assessed global studies of PFAS in cosmetics and PCPs. Second, the first-ever suspect screening and non-target analysis (NTA) using high-resolution mass spectrometry (HRMS) was conducted on cosmetic products available in Australian retail stores. The scoping review identified Polyfluoroalkyl phosphates (PAPs) as the most frequently detected PFAS, with an average concentration of 26.1 ppm, followed by perfluorooctane sulfonamides (FOSA, 4.02 ppm) and fluorotelomer sulfonamide surfactants (FTS/FTSA, 2.23 ppm). Sanitary pads, foundation products, and paper diapers were most commonly tested, while a single bronzer sample exhibited the highest concentration. Other products with notable PFAS levels included nightguards, whitening guards, and dental floss, highlighting diverse sources of exposure.

The Australian analysis revealed that most of the tested products, including those without listed fluorinated ingredients, were positive for PFAS. PAPs were the most frequently detected compounds, consistent with global findings. Foundation products demonstrated the highest detection rates, followed by lipstick, hair oil, bronzer, and masks.

This research underscores the critical need to understand PFAS contamination in cosmetics and its potential contribution to human exposure. By linking specific PFAS compounds to widely used products, this study provides valuable insights for public health advocacy, regulatory strategies, and consumer education. Addressing these gaps is essential to mitigate exposure risks, guide safer product formulations, and inform future policies. This presentation combines novel data on Australian cosmetics with a global perspective, highlighting the urgent need for regulatory and consumer-focused action on PFAS in PCPs.

3.25.P-Tu280 Rapid Screening and Targeted Analysis of PFAS in Feminine Hygiene Products

Alyssa Wicks[1]*, Sydney K. Brady*[2]*, Heather Whitehead*[1]*, Thomas Hedman*[1]*, Alison Zachritz*[3]*, Marta Venier*[2] *and Graham F. Peaslee*[1]*, (1)University of Notre Dame, United States, (2)Indiana University, United States, (3)University of Notre Dame, United States*

Per- and polyfluoroalkyl substances (PFAS) are a class of over 14,000 anthropogenic compounds that provide appealing physical properties such as water and oil repellency, and stain resistance. This in turn has led to the addition of PFAS to consumer products, including personal care products. While one study has investigated the use of PFAS in Chinese personal hygiene products, including feminine hygiene specific products, no such survey has been published for products sold in other markets. This work presents an investigation into the occurrence of PFAS in numerous types of feminine hygiene products, including sanitary pads, panty liners, incontinence underwear, menstrual cups, reusable pads, period underwear, and reusable incontinence underwear, purchased in North America and Europe.

First, particle-induced gamma-ray emission (PIGE) spectroscopy was used to screen all 78 feminine hygiene products for the presence of fluorine. PIGE is an ex-vacuo, nondestructive isotope analysis technique that screens products for their total fluorine concentrations as a surrogate for PFAS in just three minutes per sample. Then a subset of samples underwent targeted PFAS analysis of 31 analytes using liquid chromatography tandem mass spectrometry (LC-MS/MS) and an additional 12 analytes using gas chromatography-mass spectrometry (GC-MS).

Total fluorine screening identified intentional fluorination use (>110 ppm F) in at least one of the tested disposable pads, reusable pads, tampon applicators, disposable incontinence underwear, reusable incontinence underwear and plastic wrappers. Interestingly, all product categories contained at least one product without intentional fluorine concentrations. For the subset of products that underwent targeted analysis, total targeted PFAS concentrations ranged from 1.4-4500 ng/g, with a median 188 ng/g. Neutral PFAS, especially FTOHs and FTMAcrs, contributed the greatest percentage to the sum of targeted PFAS. While PFAS were observed in some feminine hygiene products, it does not appear to be an essential component of any of these products. This is supported by the total F results returning at least one product in most categories that did not contain intentional fluorination. Additionally, minimal differences observed in total F and targeted profiles of North American vs European products suggests that PFAS use in these products is widespread.

3.25.P-Tu283 High-Resolution Mass Spectrometry Screening of Per- and Polyfluoroalkyl Substances (PFAS) in Plastic Products

Xiaoyuan Guo[1]*, Guomao Zheng*[1] *and Chenglin Liu*[2]*, (1)Southern University of Science and Technology, China (Mainland), (2)YanTai University, China (Mainland)*

Per- and polyfluoroalkyl substances (PFAS) have been widely used in commercial and industrial applications, including plastics, due to their outstanding properties of chemical resistance and surface activity. Although the role of PFAS as surfactants in numerous consumer products is well known, the presence of PFAS in plastic products as additives has been seldom reported. Given the ubiquity of plastics, the use of PFAS in plastics should be of concern to avoid unexpected PFAS release. In this study, 106 plastic products representing 11 types of different plastics were chosen to examine the presence of PFAS using suspect screening and nontarget analysis by high-resolution mass spectrometry. A total of 24 PFAS from 8 classes were identified at confidence levels of 2 or above, including novel PFAS such as hydrogen-substituted perfluoroalkane carboxylates (H-PFCA), N-methyl perfluoroalkane sulfonamidoacetic acids (MeFASAA) and bis-perfluoroalkyl sulfonimides (bis-FASIs). Perfluorobutane sulfonic acid (PFBS) was the most prevalent, detected in all types of plastics and displayed relatively high detection frequencies (100% and 94%, respectively) in samples of polyamide (PA) and polycarbonate (PC). The result of subsequent quantitative analysis exhibited that the concentrations of PFBS in PC ranged from 0.2-6130 ng/g. The relatively high PFBS concentrations were mostly observed in plastic products with fire-resistant properties, implying the role of PFBS in achieving specific functions. In addition, 3H-perfluorobutane sulfonic acid (H-PFBS), a barely reported hydrogen-substituted perfluoroalkane sulfonate, was identified in samples associated with high PFBS concentration, which is regarded as the byproduct of PFBS manufacturing. A plastic-aging simulation by natural solarization and water immersion was performed to evaluate the potential of PFBS leaching from plastic products. The average leaching rate of PFBS after a 4-day simulation was 33%, indicating the great potential of PFBS to be transferred from plastic products to the environment. Overall, this study provides a crucial reference of PFAS presence in plastic products and suggests that plastics might constitute a potential source of PFAS release. Therefore, the proper use of PFAS in plastic manufacturing and stringent regulation for the disposal of wasted plastics should be emphasized.

3.25.P-Tu286 Fate and Effects of Perfluoroalkyl Substances and their Alternatives in the Marine Environment

Aasim Ali[1]*, Monica Sanden*[1]*, Stig Valdersnes*[1]*, Stepan Boitsov*[1]*, Bjorn Einar Grosvik*[1]*, Liv Softeland*[1]*, Roland Kallenborn*[2]*, Leiv Kristen Sydnes*[3]*, Christopher Higgins*[4]*, Nachiket P. Marathe*[5]*, Camilla Kirkeli*[6]*, Sylvia Frantzen*[5]*, Are Saele Bruvold*[5]*, Bente Nilsen*[1] *and Julia Storesund*[1]*, (1)IMR Norway, Norway, (2)NMBU-Norway, Norway, (3)UiB-Norway, Norway, (4)Civil and Environmental Engineering, Colorado School of Mines, United States, (5)Institute of Marine Research (IMR), Norway, (6)University of Bergen-Norway, Norway*

Per- and polyfluoroalkyl substances (PFAS) are a group of anthropogenic chemicals comprising thousands of related compounds. They are of significant environmental concern due to their persistence, potential for bioaccumulation, and toxicity. Consequently, the use of many PFAS compounds has been banned, leading to the emergence of fluorinated and non-fluorinated alternatives in various products, such as firefighting foams. However, the fate and effects of these alternatives remain poorly understood.

Our project, FEARLESS, aims to enhance our understanding of how marine organisms are impacted by PFAS and their alternatives. We focus on the transfer and transformation of PFAS and their precursors within marine food webs. FEARLESS emphasizes developing advanced analytical methods to quantify PFAS and their precursors and alternatives, assessing their toxicity and bioaccumulation in marine organisms under both laboratory and field conditions, and studying their distribution in waters influenced by firefighting foams and other point sources.

We have selected Norwegian waters influenced by runoff from onshore (Bergen Airport) and offshore

(Ekofisk and Eldfisk oil fields) point sources as our research platforms, with locations distant from known sources serving as reference sites.
This presentation will introduce the FEARLESS project and share preliminary results. Implications and consequences including the evaluation of regrettable replacement of previously banned hazardous PFASs will be discussed.

Disclaimer/Disclosure: Research council of Norway - Project Number: 335543 Fate and effects of perfluoroalkyl substances and their precursors and alternatives in Norwegian marine environments and seafood species (FEARLESS).

3.25.P Emerging and Novel Per- and Polyfluoroalkyl Substances (PFASs): Latest Findings and Innovation Towards Safe and Sustainable Alternatives

3.25.P-Tu278 A Green Transition? An Overview of Current Uses of Per- and Polyfluoroalkyl Substances in the Shift from Fossil Fuels to Green Energy

Amanda Rensmo[1]*, Juliane Gluge*[2]*, Carla A. Ng*[3]*, Martin Scheringer*[4]*, Zhanyun Wang*[5]*, Xenia Trier*[6]*, Rainer Lohmann*[7]*, Sharyle Patton*[8] *and Ian Cousins*[1]*, (1)Department of Environmental Science, Stockholm University, Sweden, (2)Institute of Biogeochemistry and Pollutant Dynamics (IBP), Department of Environmental Systems Science, ETH Zurich, Switzerland, (3)Department of Civil and Environmental Engineering, University of Pittsburgh, United States, (4)Department of Environmental Systems Science, ETH Zurich, Switzerland, (5)EMPA - Swiss Federal Laboratories for Materials Science and Technology, Switzerland, (6)Department of Plant and Environmental Sciences, Section for Environmental Chemistry and Physics, University of Copenhagen, Denmark, (7)Graduate School of Oceanography, University of Rhode Island, United States, (8)Health and Environment Program Commonweal, CA, United States*
Extensive research on climate change over the years all points in the same direction; systemic action is increasingly urgent. As a response, substantial efforts have been launched for a transition from fossil fuels to renewable alternatives, which includes the electrification of the energy, transportation and industry sectors, among other solutions. Solar panels, electric vehicles and heat pumps are some examples in this so-called green energy transition.
Still, the notion of green is without a conclusive definition. To contextualize, pollution and biodiversity loss, apart from climate change, have been shown to threaten the environment, ecosystems and human wellbeing, jointly known as the triple planetary crisis. The three dimensions (and the solutions to them) are interlinked, as can be exemplified through the use of per- and polyfluoroalkyl substances (PFAS). While they may provide important functions in the proposed green energy solutions to mitigate climate change (e.g. as binder in batteries), all PFAS in this immense chemical class are persistent, leading to significant, long-lasting pollution impacts. Thus, the question remains, can we make the current renewable energy transition a truly green energy transition? To address this matter, it is key to first understand if PFAS are essential in a green energy transition.
In this work, we present an overview of the uses of PFAS in several major energy technologies that commonly are rated as green. This includes, for instance, various battery chemistries, energy generation applications such as photovoltaics and wind turbines as well as fuel cells and electrolyzers of different types. Furthermore, we point to the need for transition to alternatives. The data were collected with an extensive literature review of both peer-reviewed literature as well as regulatory texts, surveying industrial and academic contributions to the field. In addition, interviews were conducted with both current industry parties which use PFAS and new actors providing alternative solutions.
Lastly, we emphasize the importance of highlighting the broader impacts, including PFAS pollution, associated with implementing green energy technologies to address climate change. This work contributes to this understudied field by providing knowledge and data that can be used to inform policy- and decision-making, such as improving recycling to mitigate potential emissions of PFAS or advancing alternative assessments of these technologies.

3.25.P-Tu279 Improved Prediction of Partitioning Properties for Data-Poor PFAS (Per- and Polyfluoroalkyl Substances)

Trevor N. Brown, *Jon A. Arnot and Alessandro Sangion, ARC Arnot Research and Consulting Inc. and University of Toronto, Canada*
The accurate prediction of partitioning properties of per- and polyfluoroalkyl substances (PFAS) is a current research need because these properties are required for hazard and risk assessment worldwide. However, there are limited experimental partitioning data for PFAS available, and many novel PFAS are data-poor with no measured properties. Data-drive property prediction tools such as quantitative structure-

property relationships (QSPRs) have poor predictive power for novel PFAS because of this lack of experimental data. Recently, new empirically calibrated partitioning property values for PFAS have become available in the form of poly-parameter linear free energy relationships (PPLFERs). Our open source QSPR package IFSQSAR has been updated with new data and PPLFER equations for fundamental partitioning properties including the octanol-water, octanol-air, and air-water partition ratios. IFSQSAR predictions can be accessed in the free to use EAS-E Suite online platform. The mechanistic basis of PPLFERs allows for an in-depth analysis of the unique partitioning properties of PFAS and the volume term was found to be particularly important. The updated IFSQSAR improved performance vs. experimental and empirical data for PFAS properties where available. A dataset of data-poor PFAS with partitioning properties calculated with quantum chemistry software was also used as an additional external check of predictive power. IFSQSAR showed good agreement with this external check compared to other QSPR packages that do not yet incorporate the new partitioning property data. The inclusion of the new PPLFER data and the mechanistic insights from this work could be used to help improve the predictive power of other QSPRs, and to prioritize future experimental work.

3.25.P-Tu280 Rapid Screening and Targeted Analysis of PFAS in Feminine Hygiene Products

***Alyssa Wicks**[1], Sydney K Brady[2], Heather Whitehead[1], Thomas Hedman[1], Alison Zachritz[3], Marta Venier[2] and Graham F. Peaslee[1], (1)University of Notre Dame, United States, (2)Indiana University, United States, (3)University of Notre Dame, Notre Dame, United States*

Per-and polyfluoroalkyl substances (PFAS) are a class of over 14,000 anthropogenic compounds that provide appealing physical properties such as water and oil repellency, and stain resistance. This in turn has led to the addition of PFAS to consumer products, including personal care products. While one study has investigated the use of PFAS in Chinese personal hygiene products, including feminine hygiene specific products, no such survey has been published for products sold in other markets. This work presents an investigation into the occurrence of PFAS in numerous types of feminine hygiene products, including sanitary pads, panty liners, incontinence underwear, menstrual cups, reusable pads, period underwear, and reusable incontinence underwear, purchased in North America and Europe.

First, particle-induced gamma-ray emission (PIGE) spectroscopy was used to screen all 78 feminine hygiene products for the presence of fluorine. PIGE is an ex-vacuo, nondestructive isotope analysis technique that screens products for their total fluorine concentrations as a surrogate for PFAS in just three minutes per sample. Then a subset of samples underwent targeted PFAS analysis of 31 analytes using liquid chromatography tandem mass spectrometry (LC-MS/MS) and an additional 12 analytes using gas chromatography-mass spectrometry (GC-MS).

Total fluorine screening identified intentional fluorination use (>110 ppm F) in at least one of the tested disposable pads, reusable pads, tampon applicators, disposable incontinence underwear, reusable incontinence underwear and plastic wrappers. Interestingly, all product categories contained at least one product without intentional fluorine concentrations. For the subset of products that underwent targeted analysis, total targeted PFAS concentrations ranged from 1.4 - 4500 ng/g, with a median 188 ng/g. Neutral PFAS, especially FTOHs and FTMAcrs, contributed the greatest percentage to the sum of targeted PFAS.

While PFAS were observed in some feminine hygiene products, it does not appear to be an essential component of any of these products. This is supported by the total F results returning at least one product in most categories that did not contain intentional fluorination. Additionally, minimal differences observed in total F and targeted profiles of North American vs European products suggests that PFAS use in these products is widespread.

3.25.P-Tu281 Comprehensive Characterization of Side-Chain Fluorinated Polymers in Consumer Products via Pyrolysis-GC-HRMS and NMR

***Racchana Ramamurthy**[1], Min Liu[1], Sebastian Sauve[2] and Jinxia Liu[3], (1)McGill University, Montreal, Canada, (2)University of Montreal, Canada, (3)McGill University, Canada*

Per- and polyfluoroalkyl substances (PFAS) are widely utilized in consumer and industrial applications due to their unique physicochemical properties. While research and regulatory efforts have predominantly focused on low molecular weight, non-polymeric PFAS, polymeric PFAS comprising the majority of PFAS products remain underexplored. Side-chain fluorinated polymers (SCFPs) are particularly

concerning as they degrade into environmentally persistent perfluoroalkyl acids.
SCFPs have been identified in Scotchgard impregnation sprays, with studies reporting their presence in sediments and biosolid-amended soils at concentrations up to thirty times higher than those of non-polymeric PFAS. Detecting SCFPs in environmental samples is challenging due to low extractability, the lack of chemical standards, and ionization difficulties under electrospray ionization.
This study investigates the chemical composition and polymer chemistry of 11 commercially available Scotchgard products spanning 1987 to 2022, including fabric and carpet cleaners and protectors. Pyrolysis-GC-HRMS, a novel technique requiring minimal sample preparation, was employed to characterize the bulk polymer types by analyzing pyrolysis products generated at 700 °C in single-shot mode. Pyrolysis products confirmed the presence of side-chains containing perfluorobutane or perfluorooctane sulfonamides. LC-HRMS analysis of non-polymeric PFAS indicated high amounts of PFHxS, PFOS and PFBS. One-dimensional 19F NMR revealed a transition in formulations post-2000 from C8-ECF to C4-ECF-based PFAS. Two-dimensional DOSY NMR further supported these observations, showing diffusion coefficients intermediate between non-polymeric and polymeric PFAS. DOSY NMR performed after hydrolysis experiments demonstrated that SCFPs degrade into non-polymeric PFAS, as evidenced by changes in diffusion coefficients post-hydrolysis. We use the information to piece together the chemical compositions of PFAS in these products for the first time. These findings underscore the environmental persistence and transformation potential of SCFPs in consumer products, highlighting the urgent need for further research into their environmental behavior, risks, and long-term impacts.

3.25.P-Tu282 Routine PFAS Testing of Surface Water Samples Using TOP Assay and ACQUITY™ QDa™ II Mass Detector

Henry Foody[1], Cristian Cojocariu[1], Vladimir Nikiforov[2], ***Michael Andrew McCullagh[3]*** *and David Gould[1], (1)Waters Corporation, United Kingdom, (2)NILU, Tromso, Norway, Norway, (3)Waters Corporation*

Per- and polyfluoroalkyl substances (PFAS) have increasingly become a major environmental and public health concern due to their toxic properties and tendency to bioaccumulate in living organisms, such as crops and wildlife. Global widespread use of PFAS over many decades has meant that these compounds have become common and persistent environmental pollutants. Contamination of rivers, groundwater, and drinking water sources with PFAS has been reported globally. Concern in the United Kingdom has been amplified recently by increasing reports of wastewater and sewage leaks into rivers and other water bodies; this discharge of untreated or partially treated wastewater into rivers can exacerbate trophic transfer and persistence throughout vital ecosystems and food chains. The resistance of PFAS to traditional environmental remediation techniques makes addressing their impacts particularly challenging. Traditional testing methods often fail to capture the full extent of PFAS pollution, primarily detecting legacy PFAS compounds and overlooking the myriads of precursor compounds and non-legacy PFAS compounds. The total oxidizable precursors (TOP) assay approach offers a means of bridging this gap; by oxidizing unknown PFAS precursors and intermediates and converting them into a limited set of well-characterized stable perfluoro-carboxylic and perfluoro-sulfonic acids, it allows for a more complete insight into complex environmental samples. By utilising an LC-MS approach with the ACQUITY QDa II Mass Detector, this method provides a cost-effective means of risk assessment for environmental samples. It complements traditional testing methodologies by enhancing the identification and assessment of both legacy PFAS compounds and perfluoroalkyl acid (PFAA) precursors in each sample.
In this work, eight surface water samples were collected downstream from wastewater treatment plants across the northwest of England. By comparing perfluoroalkyl carboxylic acids (PFCA) concentrations before and after oxidation, this method allows for the assessment of total PFAA precursor content in a given sample. All surface water samples tested showed a significant increase in total PFCA content post-amendment, with in-sample concentrations ranging from 67 to 2711 ng/L (ppt) - indicating a high degree of precursor contamination that traditional analytical methods may have overlooked.

3.25.P-Tu283 High-Resolution Mass Spectrometry Screening of Per- and Polyfluoroalkyl Substances (PFAS) in Plastic Products

Xiaoyuan Guo[1]*, Guomao Zheng[1] and Chenglin Liu[2], (1)Southern University of Science and Technology, China (Mainland), (2)YanTai University, China (Mainland)*

Per- and polyfluoroalkyl substances (PFAS) have been widely used in commercial and industrial applications, including plastics, due to their outstanding properties of chemical resistance and surface activity. Although the role of PFAS as surfactants in numerous consumer products is well known, the presence of PFAS in plastic products as additives has been seldom reported. Given the ubiquity of plastics, the use of PFAS in plastics should be of concern to avoid unexpected PFAS release. In this study, 106 plastic products representing 11 types of different plastics were chosen to examine the presence of PFAS using suspect screening and nontarget analysis by high-resolution mass spectrometry. A total of 24 PFAS from 8 classes were identified at confidence levels of 2 or above, including novel PFAS such as hydrogen-substituted perfluoroalkane carboxylates (H-PFCA), N-methyl perfluoroalkane sulfonamidoacetic acids (MeFASAA) and bis-perfluoroalkyl sulfonimides (bis-FASIs). Perfluorobutane sulfonic acid (PFBS) was the most prevalent, detected in all types of plastics and displayed relatively high detection frequencies (100% and 94%, respectively) in samples of polyamide (PA) and polycarbonate (PC). The result of subsequent quantitative analysis exhibited that the concentrations of PFBS in PC ranged from 0.2-6130 ng/g. The relatively high PFBS concentrations were mostly observed in plastic products with fire-resistant properties, implying the role of PFBS in achieving specific functions. In addition, 3H-perfluorobutane sulfonic acid (H-PFBS), a barely reported hydrogen-substituted perfluoroalkane sulfonate, was identified in samples associated with high PFBS concentration, which is regarded as the byproduct of PFBS manufacturing. A plastic-aging simulation by natural solarization and water immersion was performed to evaluate the potential of PFBS leaching from plastic products. The average leaching rate of PFBS after a 4-day simulation was 33%, indicating the great potential of PFBS to be transferred from plastic products to the environment. Overall, this study provides a crucial reference of PFAS presence in plastic products and suggests that plastics might constitute a potential source of PFAS release. Therefore, the proper use of PFAS in plastic manufacturing and stringent regulation for the disposal of wasted plastics should be emphasized.

3.25.P-Tu285 Simultaneous Detection of Legacy and Emerging PFAS: Gas/Particle Distribution and Partitioning in Seoul

*Mina Do[1], Syed Wasim Sardar[2] and **Jun-Tae Kim**[2], (1)Division of Energy & Environment Technology, KIST School, University of Science and Technology (UST), "Korea, Republic of", (2)Center for Climate and Carbon Cycle Research, Korea Institute of Science and Technology (KIST), "Korea, Republic of"*

Poly- and perfluoroalkyl substances (PFASs) are persistent pollutants widely detected across various environmental matrices, raising global concern due to their persistence and potential health risks. This study aims to quantify the concentrations of PFASs in the atmosphere of Seoul and assess their gas/particle partitioning behavior, with a focus on providing insights critical to air quality management and regulatory strategy development. The primary challenge addressed is determining the concentration profiles and distribution patterns of different PFAS compounds in Seoul s atmosphere, focusing on their partitioning between gas and particle phases.

To achieve this, atmospheric samples were collected from February 10 to March 16, 2024, at the Korea Institute of Science and Technology (KIST) in Seoul, using high-volume air sampling equipment. Particulate-phase PFASs were captured on quartz fiber filters, while gas-phase compounds were collected using polyurethane foam (PUF)/ activated carbon felt (ACF)/ PUF sandwiches. Sample analysis was conducted via high-performance liquid chromatography coupled with a triple quadrupole mass spectrometer (HPLC-MS/MS), which enabled the quantification of individual PFAS compounds. Results indicate that short-chain PFASs, including perfluorobutanoic acid (PFBA) and perfluorobutanesulfonic acid (PFBS), were the most prevalent, with a tendency to exist in the gas phase, suggesting higher volatility and potential for long-range atmospheric transport. Conversely, long-chain PFASs like perfluorooctanoic acid (PFOA) and perfluorooctanesulfonic acid (PFOS) were predominantly associated with particles, indicating a greater tendency to remain localized. The total concentration of PFASs ranged from 3.19 to 29.2 pg/m^3, with a median of 5.42 pg/m^3. These findings highlight distinct atmospheric behaviors based on PFAS chain length and contribute valuable data for urban air quality management. Ongoing monitoring is essential to fully assess the environmental impact of legacy and emerging PFASs.

3.25.P-Tu286 Fate and effects of perfluoroalkyl substances and their alternatives in the marine environment

***Aasim Ali**[1], Monica Sanden[1], Stig Valdersnes[1], Stepan Boitsov[1], Bjorn Einar Grosvik[1], Liv Softeland[1], Roland Kallenborn[2], Leiv Kristen Sydnes[3], Christopher Higgins[4], Nachiket P. Marathe[5], Camilla Kirkeli[6], Sylvia Frantzen[5], Are Saele Bruvold[5], Bente Nilsen[1] and Julia Storesund[1], (1)IMR Norway, Norway, (2)NMBU-Norway, Norway, (3)UiB- Norway, Norway, (4)Civil and Environmental Engineering, Colorado School of Mines, United States, (5)Institute of Marine Research (IMR), Norway, (6)University of Bergen- Norway, Norway*

Per- and polyfluoroalkyl substances (PFAS) are a group of anthropogenic chemicals comprising thousands of related compounds. They are of significant environmental concern due to their persistence, potential for bioaccumulation, and toxicity. Consequently, the use of many PFAS compounds has been banned, leading to the emergence of fluorinated and non-fluorinated alternatives in various products, such as firefighting foams. However, the fate and effects of these alternatives remain poorly understood.
Our project, FEARLESS, aims to enhance our understanding of how marine organisms are impacted by PFAS and their alternatives. We focus on the transfer and transformation of PFAS and their precursors within marine food webs. FEARLESS emphasizes developing advanced analytical methods to quantify PFAS and their precursors and alternatives, assessing their toxicity and bioaccumulation in marine organisms under both laboratory and field conditions, and studying their distribution in waters influenced by firefighting foams and other point sources.
We have selected Norwegian waters influenced by runoff from onshore (Bergen Airport) and offshore (Ekofisk and Eldfisk oil fields) point sources as our research platforms, with locations distant from known sources serving as reference sites.
This presentation will introduce the FEARLESS project and share preliminary results. Implications and consequences including the evaluation of regrettable replacement of previously banned hazardous PFASs will be discussed.

Disclaimer/Disclosure: Research council of Norway- Project Number: 335543 Fate and effects of perfluoroalkyl substances and their precursors and alternatives in Norwegian marine environments and seafood species (FEARLESS) .

3.25.P-Tu287 Per- and Polyfluoroalkyl Substances (PFAS) Levels in Urban Stormwater Runoff Demonstrate the Importance of Outdoor Sources

Kelly Moran[1]*, Katherine Peter*[2]*, Alicia Gilbreath*[3]*, Adam Wong*[3]*, Donald Yee*[3]*, Ezra L Miller*[1]*, Andrew Patterson*[4]*, Nicole Fitzgerald*[5]*, Richard Grace*[6]*, Christopher Higgins*[7]*, Edward P. Kolodziej*[2] *and Rebecca Sutton*[1]*, (1)San Francisco Estuary Institute, Richmond, United States, (2)University of Washington Tacoma, United States, (3)San Francisco Estuary Institute, United States, (4)Eurofins, United States, (5)Colorado School of Mines, United States, (6)SGS AXYS, United States, (7)Colorado School of Mines, Golden, United States*

On behalf of the Regional Monitoring Program (RMP) for Water Quality in San Francisco Bay (California, USA), we evaluated the occurrence of per- and polyfluoroalkyl substances (PFAS) in stormwater runoff. The RMP started monitoring PFAS in 2006, generating data that now rank the class as a high concern in San Francisco Bay due in part to fish tissue concentrations that exceed some human health risk thresholds. In urban to peri-urban watersheds such as those surrounding San Francisco Bay, stormwater runoff is a major pathway by which contaminants enter aquatic ecosystems. Like >85% of the USA population, the population in this region has separated outdoor (stormwater) and indoor (sewer) drainage systems. Time-averaged composite sampling of stormwater runoff focused on storms in highly developed watersheds, with complementary sampling in less-urban reference watersheds, for a total of more than 30 sample sets over five wet seasons. Samples were analyzed for the 40 PFAS listed in EPA Method 1633 via liquid chromatography coupled to tandem mass spectrometry, with subsets of samples subjected to more extensive targeted analysis of analytes such as polyfluoroalkyl phosphate diesters (diPAPs), and the total oxidizable precursors (TOP) assay to measure unknown precursors. In initial data, most frequent detections were of perfluorocarboxylic acids (PFCAs), perfluorosulfonic acids (PFSAs), and diPAPs. Measured concentrations rivaled those in effluents from the region s municipal wastewater treatment plants. In addition to firefighting foams and metal-plating mist suppressants, PFAS sources particularly relevant to outdoor urban environments include outdoor paints and coatings, roofing materials, textiles, solar panels, artificial turf, and automotive products. (The specific PFAS used in many of these products likely need to undergo transformation to form the intermediate and terminal products, like PFCAs and PFSAs, analyzed in this study.) Rainwater may contribute to PFAS in stormwater, though concentrations reported in rainwater elsewhere were in the lower range of concentrations detected in this study, and observed PFAS concentrations were generally significantly higher in highly developed watersheds relative to reference watersheds. PFAS sources, transformation, and transport processes will need more detailed studies to inform management of this complex pollutant class. Results emphasize the role of urban stormwater runoff in PFAS transport to surface waters.

3.25.P-Tu288 Emerging Patterns and Distributions of Select Per- and Polyfluoroalkyl Substances (PFAS) in Nebraska Drinking Water

Sarah Tucker[1]*, Daniel D. Snow*[2]*, Rachael Birn*[1]*, Elizabeth Cole*[1]*, Alex Egbuchiem*[1]*, Julia (He) Bai*[1]*, JoEllyn McMillan*[1]*, Kristina Kintziger*[1] *and Aaron Yoder*[1]*, (1)University of Nebraska Medical Center,*

United States, (2)University of Nebraska Lincoln, United States
Per- and polyfluoroalkyl substances (PFAS) have dispersed widely into the environment from industrial and consumer uses, threatening water quality across the globe. Multiple research groups have detected PFAS in tap and bottled water in the United States (US) and many other countries. Pattern and concentrations of PFAS are influenced by water source, location, environment, and many other factors. At present there is limited information on PFAS occurrence in private wells. The primary objective of this research is to sample and measure PFAS in residential private and public water sources located around known or suspected point sources in Nebraska to characterize the risk of PFAS exposure through drinking water. Water samples were collected from randomly selected, mostly rural residences around seven different sites in Nebraska. Samples were extracted and analyzed by liquid chromatography tandem mass spectrometry following US Environmental Protection Agency (USEPA) Method 1633. Participants were surveyed at the time of water sample collection to help evaluate factors which may contribute to exposure. Well water PFAS concentrations and survey variables will be used to generate a USEPA hazard index (HI) to identify households and risk factors contributing to elevated risk. Preliminary results reveal that at least one PFAS compound was present above the detection limit in 89% of the water samples (N = 84). The most frequently detected PFAS were PFOSA (83%), PFOA (52%), PFBS (43%), PFHxS (42%), and PFBA (23%). The distribution of PFAS compounds differed by location, and regulated concentrations were below the USEPA maximum contaminant levels (MCLs). Eighty percent of the samples were collected from private wells. Fifty-five percent of participants reported their water was being treated. The most common types of water treatment were water softener (47%) and reverse osmosis (30%). Preliminary results provide quantified levels of PFAS in several residential water samples, with emerging patterns and distributions of PFAS in rural Nebraska. The next steps in this project include geospatial analysis, social vulnerability and health outcome analysis, and HI assessment for better prediction of drinking water exposure routes.

3.25.P-Tu289 Wildlife Affected by PFAS from Remote Areas in Central Europe

Viktoria Mueller[1], *Fernanda P. Balbinot*[2], *Marcia F. Mesko*[2], *Joerg Feldmann*[3], *Marc Phreis*[3], *Robert Brodschneider*[3], *Andy Kindness*[4], *Till Schroeder*[3], *Raquel Gonzalez de Vega*[3], *Jan Borovicka*[5], *Jan Koschorreck*[6] *and Michael Buchebner*[7], *(1)The James Hutton Institute, Austria, (2)Universidade Federal de Pelotas, Brazil, (3)University of Graz, Austria, (4)The James Hutton Institute, United Kingdom, (5)Czech Academy of Sciences, Czech Republic, (6)Umweltbundesampt, Germany, (7)Nationalpark Kalkalpen, Austria*
With the wide use and large number per and polyfluoroalkyl substances (PFAS), paired with their physical and chemical properties originating from the high C-F bond energy makes them persistent in the environment. Despite regulatory measures phasing out several PFAS, their presence in the environment is still detectable due to their long half-life, and transformation of precursor compounds. Wildlife in particular are vulnerable to PFAS exposure through the uptake of contaminated food and water, leading to the bioaccumulation of PFAS in various tissues. This makes wildlife valuable sentinel animals for biomonitoring PFAS exposure to humans.
In this study we sampled livers, kidneys, and brains of animals from various diet and environments (national park, mountanious regions and urban areas to assess their PFAS burden by analysing extractable organofluorine (EOF) and total fluorine (TF) analyses alongside targeted quantification of over 31 PFAS compounds. The target analysis included legacy PFAS, emerging PFAS, and ultrashort-chain PFAS (chain length <C3), enabling the detailed characterisation of specific PFAS as well as sum parameters. This multi platform approach provides new insights into the PFAS exposure across a diverse ecological centext. The results show that diet, but most importantly habitat influences PFAS pattern and concentrations observed in the tissues, highlighting the interaction between environmental exposure pathways and uptake. The results also highlights the importance of biomonitoring PFAS.

Disclaimer/Disclosure: The authors thank umava National Park staff and the hunters for providing the samples. V.M. thanks the Macaulay Development Trust for her scholarship and T.S. thanks the EU for Erasmus scholarships FPB thanks Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq) and Fundação Coordenação de Aperfeiçoamento de Pessoal de Nível Superior (CAPES) for her scholarship.

3.25.P-Tu290 Tissue-Specific Biodistribution of Emerging Per- and Polyfluoroalkyl Substances (PFAS) for Biomagnification Estimation in a Process-Based Aquatic Trophic Model

***Jingxiang Rockson Liu*[1]**, *Luhua You[2], Wai Yee Jason Ku[2] and Karina Yew-Hoong Gin[1], (1)Department of Civil and Environmental Engineering, National University of Singapore, Singapore, (2)NUS Environmental Research Institute, National University of Singapore, Singapore*

This study investigates the tissue-specific distribution of emerging per- and poly-fluoroalkyl substances (PFAS), including GenX derivatives and fluorotelomers, in fish subjected to chronic environmental exposure in the tropical coastal waters surrounding Singapore. Understanding the biodistribution of these compounds is essential for assessing their bioaccumulative behaviours and potential toxicological impacts. While extensive research has been conducted on legacy perfluoroalkyl acids and has identified the liver as the primary accumulation site, tissue-specific distribution of the emerging GenX and fluorotelomers remains poorly understood. These compounds differ from legacy PFAS due to their higher molecular weight and tendency to undergo biotransformation. This study quantifies the concentrations of five GenX compounds and six fluorotelomers in various fish tissues, including liver, muscle, intestine, bone, skin, and tail, using targeted LC-MS/MS analysis. The tissue-specific distribution factors and body burdens are individually assessed and incorporated into a site-specific process-based aquatic trophodynamic model to evaluate the role of individual tissues in the overall bioaccumulation process. By comparing model outputs with empirical data, this study refines biomonitoring strategies by identifying tissues most suitable for estimating trophic transfer and ecological burdens of GenX and fluorotelomers in aquatic ecosystems.

3.25.P-Tu291 Preliminary Assessment of the Zebra Mussel (*Dreissena polymorpha*) as a Sentinel Organism to Monitor Legacy and Emerging PFAS in an Urban River: A case Study on the Seine River (France)

***Pierre Labadie*[1]**, *Antoine Fructuoso[2], Patrick Pardon[2], Marc Bonnard[3] and Helene Budzinski[1], (1)CNRS, Universite de Bordeaux, UMR 5805 EPOC, France, (2)University of Bordeaux, UMR 5805 EPOC, France, (3)Universite de Reims, UMRI-02 SEBIO, France*

Per- and polyfluoroalkyl substances (PFAS) are ubiquitous in aquatic environments. A recent shift toward emerging PFAS is calling for new data on their occurrence and fate. Understanding their bioaccumulation and its drivers is fundamental for risk assessment purposes. Sentinel organisms, such as zebra mussels, may be used to provide an integrated measure of pollutant bioavailability over time and thereby monitor water quality.

Here, we present preliminary data on the use of the zebra mussel as a sentinel organism to monitor legacy and emerging PFAS in a major urban river, the Seine River (France).

Individuals collected from a reference lake were transplanted for three weeks at five locations along the Seine River and some of its tributaries following an expected upstream-downstream gradient. Three campaigns were performed in autumn (2020, 2021 and 2023). Campaigns took place in autumn (2020, 2021, and 2023). At the downstream sites, sediment traps were deployed to collect suspended particulate matter (SPM), and bed sediments were also sampled. A total of 36 PFAS were monitored, including legacy compounds such as PFCAs and PFSAs but also more emerging chemicals rarely monitored in biota such as FTSAs, ethers or sulfonamidoalkyl betaines.

Among the 36 analysed PFAS, 17 were detected in sediments and SPM. PFOS, PFDoDA, and 6:2 FTAB were systematically found. 5:3 FTCA was detected in 4/5 sites, while 8:2 FTAB appeared sporadically at two downstream sites. Alternative PFAS like 6:2 and 8:2 Cl-PFESA or GenX were absent, while ADONA was found at two sites at very low concentrations. Molecular patterns were dominated by 6:2 FTAB, followed by 5:3 FTCA and L-PFOS. This highlights a notable contribution from emerging PFAS. In exposed zebra mussels, PFAS levels were significantly higher than in controls (i.e. up to 70 ng/g wet weight). Contrary to previous results obtained on fish from this river stretch, the molecular profile of PFAS in mussel tissues was generally very similar to that observed in abiotic samples. In particular, there was a notable contribution from relatively reactive PFAS, i.e. 10:2 FTSA or 6:2 FTAB, probably due to the limited capacity of zebra mussels to metabolise xenobiotics. This pattern seems therefore a fairly accurate reflection of the exposure environment, making zebra mussels reliable indicators of environmental exposure. Additional data are being collected to strengthen the use of zebra mussels in PFAS biomonitoring.

3.25.P-Tu292 Toxicological Effects of PFOS and PFBS on Rainbow Trout: In Vitro and In Vivo Approaches

Monica Hamann Sandgaard *and Joachim Sturve, University of Gothenburg, Sweden*

Per- and polyfluoroalkyl substances (PFAS), such as perfluorooctanesulfonic acid (PFOS) and perfluorobutanesulfonic acid (PFBS), are environmental contaminants of concern due to their persistence and potential toxic effects on aquatic life. This study aims to evaluate the effects of PFOS and PFBS on rainbow trout (*Oncorhynchus mykiss*) using in vitro (liver and gut cells) and in vivo (whole organism) experimental models. The objectives were to compare the biological impacts of these substances and assess the relevance of in vitro systems for predicting whole-organism responses. Rainbow trout liver and gut cells were exposed to two concentrations of PFOS and PFBS in vitro using a co-culture experimental setup. This was conducted using a co-culture experimental design, wherein liver cells were cultured in wells of 6-well plates, while gut cells were maintained in mesh inserts within the same wells. Additionally, experimental setups included liver cells cultured with an empty insert (i.e., no gut cells) and a setup with liver cells only, to facilitate comparative analysis. In parallel, juvenile rainbow trout were exposed to these compounds through their diet under controlled laboratory conditions. RNA was extracted from both in vitro liver and gut cells and from liver and gut tissues in vivo. Biomarker analysis focused on gene expression changes related to oxidative stress, lipid metabolism, thyroid hormone regulation, inflammation, and detoxification pathways. The research advances our understanding of PFOS and PFBS toxicity in aquatic organisms and highlights the complementary roles of in vitro and in vivo approaches in ecotoxicological studies.

Disclaimer/Disclosure: This research received financial support from VILLUM FONDEN under grant number VIL59842, in addition to funding from the CONTRAST project, which is financed by the European Union.

3.25.P-Tu293 Deriving Soil Threshold Values for PFASs – Navigating Toxicity, Exposure, and Practical Limits

***Elvira Rudin*[1]**, *Juliane Gluge[1], Basil Thalmann[2] and Martin Scheringer[1], (1)Institute of Biogeochemistry and Pollutant Dynamics (IBP), Department of Environmental Systems Science, ETH Zurich, Switzerland, (2)Institute of Natural Resource Sciences, ZHAW, Switzerland*

Per- and polyfluoroalkyl substances (PFASs) pose a major challenge for chemical soil protection. Due to their decades-long use in various applications and their persistence, PFASs are ubiquitous in the environment and in humans. Additionally, effects on human health and ecosystems have been observed at concentrations commonly found in foodstuff or the environment.

Various countries are now developing soil threshold values for PFASs, using different frameworks focusing on ecotoxicity, human health, or background contamination levels. In Switzerland, a new framework has recently been developed and proposed to derive soil threshold values for agricultural soils. This framework has been applied to PFASs and several challenges have been identified.

Firstly, the selection of substances to prioritize is complex due to the diversity of PFASs. There are several thousand PFASs with different behaviour, occurrence, and toxicity. Second, the lack of data complicates the derivation at several points. For many PFASs, there are knowledge gaps, which include unknown levels for background contamination in soil or foodstuff, insufficient knowledge on transfer to agricultural crops or animals, or not yet established tolerable weekly intake (TWI). Thirdly, aligning soil threshold values with already existing guideline values, such as maximum levels in foodstuff, drinking water guidelines, or TWI is an additional challenge. Finally, the practical application of soil threshold values for PFASs is complicated by the widespread presence of PFASs in the environment. High background levels make it difficult to establish thresholds that protect human and environmental health without rendering many agricultural areas non-compliant and therefore no longer usable for food production. This illustrates the difficulty of reconciling protective standards with feasibility and enforceability.

This study addresses the above challenges and identifies ways to overcome them to establish feasible, science-based soil threshold values for PFASs. It additionally identifies research gaps critical to regulation, demonstrating how targeted research can support the development of improved soil threshold values.

3.25.P-Tu294 Enhancing Removal Efficiency of Short-Chained PFAS Using a Two-Step Treatment Train: Flocculation and Sorption

***Ingvild Haneset Nygaard*[1]**, *Erlend Sormo[2], Sarah Hale[3], Aasgeir R. Almaas[1], Roland Kallenborn[1], Fedor Kryuchkov[1] and Haakon Austad Langberg[2], (1)Norwegian University of Life Sciences, Norway, (2)Norwegian Geotechnical Institute (NGI), Norway, (3)DVGW-Technologiezentrum Wasser, United Kingdom*

The presence of ultra-short and short-chain per- and polyfluoroalkyl substances (PFAS) present significant challenges in treating complex landfill leachates. Organic matter in soil and landfill leachate competes

with PFAS for sorption sites on carbonaceous sorbents, leading to reduced treatment efficiency and increased treatment costs. While activated carbon is commonly used, biochar may provide a sustainable alternative due to its lower environmental footprint and reduced cost as it is produced from waste materials. This study evaluates whether a two-step treatment train combining coagulation and flocculation with sorption can enhance the removal of ultra-short and short-chain PFAS from contaminated landfill leachate. The coagulants and flocculants have been shown to precipitate most of the long-chain PFAS, while shorter chained PFAS are less efficiently removed. We hypothesize that removal of negatively charged short-chain PFAS will be achieved by sorption of complexes, formed by flocculants and short-chain PFAS remaining in suspension, to the mesoporous biochar. We further hypothesize that this two-step approach, i.e., flocculation followed by sorption, will be a cost-efficient and more environmentally friendly approach to addressing the challenge of short-chain PFAS in complex landfill leachate.
Preliminary results show that 34-97% of targeted PFAS can be removed from landfill leachate via flocculation, with longer-chained PFAS being more efficiently removed than shorter ones. Follow up work is now investigating spiked samples with a coagulation and flocculation step followed by sorption using biochar. Key water parameters will be monitored throughout the process, with PFAS analyses conducted post-jar test and post-batch experiment.
We will examine the interaction of ultra-short, short- and long-chained PFAS with organic matter during treatment. The test will be optimized with spiked samples before testing with landfill leachate. Quality assurance and control measures include running parallels, method blanks, sample blanks, and other controls.
The effect of various factors on removal efficiency, including coagulant and flocculant materials and dosages, organic matter content, and PFAS profiles, will be presented. We anticipate this research will advance water treatment strategies for short-chained PFAS and provide deeper insights into their removal mechanisms when using coagulants and flocculants in combination with sorption using biochar.

3.25.P-Tu295 Soil Column Chromatography Coupled with Mass Spectrometry to Investigate the Sorption of Per- and Polyfluoroalkyl Substances (PFASs)

***Anh T. Ngoc Do*[1]**, *Nobuhide Fujitake[2] and Satoshi Endo[1], (1)National Institute for Environmental Studies (NIES), Japan, (2)Kobe University, Japan*

The transport of per- and polyfluoroalkyl substances (PFASs) in soil environment has attracted public concern because of their adverse effects. This study introduced a soil column chromatography (SCC) approach combined with liquid chromatography mass spectrometry (LC-MS) to characterize the soil sorption behavior of PFASs. Although SCC is an established approach, the PFAS of concern need MS detection because they are not measurable with a UV detector. This method is expected to overcome existing challenges and facilitate the acquisition of comprehensive data sets. To do so, the specific aims of the study are 1) to validate the SCC method for non-fluorinated neutral and anionic chemicals by HPLC-UV and PDA analysis; 2) to apply the SCC for LC-MS analysis and compare the LC-MS data to HPLC-PDA data and 3) to obtain the sorption coefficient (Koc, kg/L) for PFASs by using the measured retention times of PFASs. The results showed that a newly customized SCC device using a stainless-steel column with dimensions of 20 mm in length x 3 mm in internal diameter and silica ($SiO2$, 3 µm particle size) as a dilution material is optimal. A comparison of sorption data for the non-fluorinated neutral chemicals reveals that there is no significant difference between the HPLC-PDA and LC-MS systems, and those sorption data are consistent with the data reported in the literature. The obtained LC-MS data showed that no notable variation was observed between retention time of the test PFASs and the dead time of bromine as chosen tracer, indicating the weak sorption of the PFASs to the selected peat. This research shows the potential of coupling the SCC approach with MS to obtain soil sorption data for PFASs, which should contribute to risk assessment and chemical management practices.

3.25.P-Tu296 Liquid Chromatography Retention Factors as a Metric for Hydrophobic Sorption Properties of Anionic PFAS

Satoshi Endo *and Sadao Matsuzawa, National Institute for Environmental Studies (NIES), Japan*

Partitioning and adsorption from water to non-aqueous phases are important processes that determine the environmental behavior and biological effects of contaminants. For neutral compounds, it is common practice to use the octanol/water partition coefficient (Kow) as an indicator of solute hydrophobicity and predict the corresponding partition coefficients. However, many per- and polyfluoroalkyl substances (PFAS) exist as anions in water at environmental pH, rendering Kow irrelevant as a hydrophobicity metric. In this study, the retention times of 39 anionic PFAS and 20 non-fluorinated anionic surfactants were measured in reversed-phase liquid chromatography using an octadecyl (C18)-bonded silica column

and evaluated as a potential hydrophobicity indicator.
Anionic PFAS and analogous non-fluorinated surfactants were dissolved in methanol and injected (1 ?L) into a single quadrupole LC/MS equipped with a Kinetex EVO C18 column (5 µm, 2.1 mm i.d. × 30 mm) to measure retention times (tr). Isocratic elution was applied with methanol/water mixtures containing 10 mM ammonium acetate and 0.2 mM ammonia. The column dead time t0 was measured using glyceric acid as a tracer. The retention factor k was calculated as (tr - t0)/t0. The value of k at 0% methanol (k0) was extrapolated from k s measured at higher methanol fractions (up to 80%). For long-chain PFAS, k0 had to be extrapolated over long distances from measurements at high methanol concentrations. Nevertheless, by measuring a series of PFAS with different chain lengths and using a highly consistent log k increment by adding -CF2- unit to the molecule, it was possible to obtain consistent k0 values even for long-chain PFAS. The k0 values obtained were compared with the soil organic carbon/water, phospholipid membrane/water, and air/water interfacial partition coefficients, showing a high logarithmic correlation in all cases. Since the measurement of k0 is reproducible and accurate, it can be used to estimate various hydrophobicity-related partition coefficients of anionic PFAS.

Disclaimer/Disclosure: This work was supported by the Environment Research and Technology Development Fund 3-2102 (JPMEERF20213002) of the Environmental Restoration and Conservation Agency provided by the Ministry of Environment of Japan.

3.25.P-Tu297 Evaluating PFAS Adsorption with Potash Alum and Chitin-Modified Biochar

Kayla Collins*, Nigel Jackson, Niesha Jacobs, Ryann Hudson, Joshua Akinola and Eguono Wayne Omagamre, University of Maryland Eastern Shore, United States*

Per- and polyfluoroalkyl substances (PFAS) are persistent environmental pollutants that threaten water quality and ecosystem health. This study investigates the adsorption efficiency of potash alum-modified biochar and chitin-modified biochar for removing PFAS from contaminated water. Potash alum was innovatively generated from recycled soda cans, demonstrating a sustainable approach to upcycling waste materials. Preliminary assessments suggest that the alum-modified biochar exhibits a more crystalline structure, potentially enhancing adsorption efficiency. The goal of this project is to target short-chain PFAS removal, as these compounds are more mobile and pose unique challenges for conventional remediation techniques. The hypothesis driving this research is that introducing Al^{3}? onto the biochar surface may shift its binding mechanism from primarily hydrophobic interactions to enhanced electrostatic attraction, improving adsorption of short-chain PFAS. Similarly, chitin-modified biochar, with its inherent amine and hydroxyl functional groups, is hypothesized to strengthen adsorption via hydrogen bonding and electrostatic interactions with PFAS functional groups. Surface characterization is ongoing to evaluate the effects of potash alum and chitin treatments on biochar properties, including surface area, porosity, crystallinity, and functional groups. Adsorption experiments will assess the performance of modified and unmodified biochar using a mixture of 10 PFAS compounds, comprising both short-chain carboxylic acids (PFBA, PFPeA, PFHxA, PFHpA) and long-chain carboxylic acids and sulfonates (PFOA, PFNA, PFDA, L-PFBS, PFHxS, PFOS). Percent removal of PFAS will be measured to determine the effectiveness of the modifications in enhancing adsorption performance. This research highlights the dual environmental benefits of PFAS removal and waste recycling through innovative biochar modification strategies. By focusing on short-chain PFAS, which are typically more difficult to adsorb, this work aims to contribute to eco-friendly and sustainable solutions for PFAS remediation. Findings from adsorption studies and surface characterizations will be presented at the conference, showcasing the potential of alum- and chitin-modified biochar as promising tools for addressing PFAS contamination in water systems.

3.25.P-Tu298 Contributions on the Development, Implementation and Assessment of SSbD Alternatives to PFASs in the Packaging Industrial Sector

*Pau Camilleri, **María Rivero García**, Javier Alcodori and Arantxa Ballesteros Riaza, ITENE, Spain*

Comprising more than 4.700 chemicals, per and polyfluorinated alkyl substances (PFAS) are a group of man-made chemicals, widely used to provide water and oil repellency, that accumulate over time in humans and in the environment. Also known as forever chemicals, they are extraordinarily persistent in the environment and in our bodies, being toxic at extremely low levels (i.e. parts per quadrillion), posing significant risks to our health.
The EU's Chemicals Strategy for Sustainability puts PFAS policy in the spotlight. Nowadays, a number of PFAS are on the REACH Candidate List of substances of very high concern (SVHC), while several additional PFAS are on the list for evaluation. At the same time, the European Commission is committed to phasing out all PFAS, allowing their use only where they are proven to be irreplaceable and essential to society.

Regarding their use in surface treatments and coatings, PFAS are widely used to provide water and oil repellency for various applications as non-sticking utensil pan surfaces, water repellent and anti-soiling treatment for textile, food-contact anti-soiling coating on paper or cardboard packaging. Alternative PFAS-free products are currently available on the market, but not answering all market requirements in terms of long-term repellency properties (usually hydrophobic but not oleophobic) limiting their widespread use.
The BIO-SUSHY project aims at developing innovative coating solutions that will be designed to meet the policy ambition of the EU s chemical strategy for sustainability toward a toxic free environment. Under the scope of the project, bio-based thermoplastic powder coating formulations for the packaging industrial sector will be developed, following the Safe and Sustainable by Design (SSbD) methodology to ensure safety and environmental performance.
In this regard, an operating SSbD framework for strategic development of hazard-safe PFAS-free repellent bio-based hybrid coatings is being developed. BIO-SUSHY will contribute to the definition of the criteria in terms of safety and sustainability needed for the development of strategies applied to novel coatings. The consideration of safety and sustainability dimensions, the definition of their criteria applied to novel coatings, and the construction and demonstration of the SSbD Framework in which they are integrated, ultimately constitute guidance for the development of safer and more sustainable materials.

3.25.P-Tu299 Implementing the Safe and Sustainable by Design (SSbD) Criteria at an Early Innovation Stage to Develop Biobased PFAS Alternatives for Textiles

Steffen Schellenberger, *Mikael Jarn and Anna-Karin Hellstrom, RISE Research Institutes of Sweden, Sweden*

As a result of the ongoing regulation of per- and polyfluoroalkyl substances (PFAS), the textile industry is phasing out PFAS-based materials in its products. The lack of sufficient information about the human and environmental risks of alternatives has led to an uninformed substitution process. A key functional chemical, durable water repellents (DWRs) based on side-chain-fluorinated polymers, has often been replaced with silicone polymer DWRs. These are associated with the release of cyclic siloxanes, such as octamethylcyclotetrasiloxane (D4), which is classified as a substance of very high concern (SVHC). In other cases, alternatives marketed as PFAS-free or C0 chemistries have been used without providing information on their chemical hazards. The industry urgently needs better information about the hazards and environmental impacts to choose PFAS alternatives in textiles.
In the European project BIOSUSTEX, we are developing new biobased DWRs for cellulosic fabrics and aim to implement the Safe and Sustainable by Design (SSbD) framework suggested by the EU at an early innovation stage to guide these developments. At this low technology readiness level (TRL), a lack of information on toxicity, exposure risks, and inventory data for life cycle assessment (LCA) makes a sufficient SSbD assessment challenging so far. We present a preliminary methodology overview of how to incorporate new models based on in silico predictions and qualitative life cycle-based risk mapping approaches to assess the SSbD principles for PFAS alternatives in textiles during the design stage.

3.26.P Mercury in the Environment - Science to End Mercury Pollution

3.26.P-Tu300 Mercury in Seafood - A Persuasive Argument to Reduce Mercury Pollution from Small-scale Gold Mining Activities?

Amanda J. Reichelt-Brushett[1] *and Yusthinus Male*[2]*, (1)Southern Cross University, Australia, (2)University of Pattimura, Indonesia*

Seafood products are an important source of protein and are rich in essential minerals, vitamins, and polyunsaturated fatty acids such as omega-3. However, despite the numerous health benefits gained from seafood consumption, these products can contain harmful metals, including mercury. Small-scale gold mining commenced on Buru Island, Maluku Province, Eastern Indonesia in 2011 and has resulted in mercury contamination through the estuary and marine environment. Concern was raised by the Buru Island community and at nearby Ambon City about the mercury levels in their locally sourced seafood. We collected triplicate seafood samples from fish markets on Buru Island (12 species) and Ambon (15 species) and compared these with a reference data set from a fish market in Eastern Australia (19 species) and investigated total and methyl mercury concentrations in tissue and skin. Various Maximum Levels (MLs) permissible in seafood were exceeded in tissue and skin of individuals of several species from all market locations and were most strongly linked to trophic order, with the highest concentration recorded in muscle of the blacktip shark (4590 µg/Kg). Individuals with unusually elevated mercury had a high proportion in the form of methylmercury (44-99%). There was considerable variation between individuals of the same species. Consumption scenarios show how avoidance of some species can ensure diets remain below the provisional tolerable weekly intake (PTWI). Local health advisors promote the importance of dietary protein and in Maluku Province the marine environment is its major source.

Disclaimer/Disclosure: Some funding support for this study came from Southern Cross University and University of Pattimura.

3.26.P-Tu301 Mercury on the Rise in Aquatic Biota from Freshwater andMarine Ecosystems: A South African Perspective

***Johannes Hendrik Erasmus**, Wynand Malherbe, Nico Smit and Victor Wepener, Water Research Group, Unit for Environmental Sciences and Management, South Africa*

Mercury (Hg) contamination in various aquatic ecosystems is a major concern as global emissions are increasing. These Hg emissions enter aquatic ecosystems via various anthropogenic sources, including artisanal and small-scale gold mining, coal combustion power stations and non-ferrous metal production. All of these major sources of Hg are occurring in South Africa (SA), resulting in SA being one of the top ten contributors of Hg emissions globally. When Hg enters the environment, it does not only act as a local contaminant but can be transported by long-distance atmospheric deposition, where our data have shown that it is readily accumulated in biota and biomagnified in food webs. This study determined the current Hg contamination status of SA in freshwater and marine ecosystems by assessing various environmental matrices and the transfer of Hg in the environment. It is evident that Hg concentrations in SA have increased over the last decade, in both the freshwater and marine environment, and is present in biota from these systems. When applying the USEPA human health risk assessment to consumption of fish, it was found that Hg can pose non-carcinogenic health risks to human consumers. Even though SA is a party to the Minamata Convention, that aims to reduce the effects of Hg on environmental and human health, more than 80% of the power generation in SA still relies on coal combustion power stations. Increased artisanal and small-scale gold mining activities also contribute to elevated Hg concentrations, especially in aquatic ecosystems. This study highlights the need to continuously monitor Hg concentrations in both freshwater and marine ecosystems to assess the exposure and effects of Hg on environmental and human health.

3.26.P-Tu302 Innovative High-Throughput Method for Ultratrace Methylmercury Detection in Biological Samples: A Breakthrough in Biomonitoring for Public Health Risk Assessment

***Davide Spanu**, Damiano Monticelli and Sandro Recchia, University of Insubria, Italy*

Methylmercury (MeHg), a highly toxic neurotoxin, accumulates through the food chain, particularly via fish consumption, posing significant health risks. Current biomonitoring often measures total mercury (Hg), neglecting the selective detection of MeHg, which is critical for accurate exposure and risk assessment. This gap limits our understanding of MeHg's true impact on human health.
To address this challenge, we developed an innovative, rapid, and highly sensitive method for MeHg determination in fish tissue and human hair using Inductively Coupled Plasma Mass Spectrometry (ICP-MS) paired with a custom low-pressure column. Unlike traditional methods requiring High-Performance Liquid Chromatography (HPLC), this streamlined approach employs an anion exchange resin that blocks inorganic Hg species, allowing for the selective elution of MeHg. This reduces complexity while maintaining high accuracy and efficiency.
Our method features a 15-minute ultrasound-assisted extraction with an optimized HCl-HBr-thiourea mixture, delivering a low detection limit of 0.05 ?g/kg (in solid samples when using typical sample size of 100 mg) and minimizing matrix interference. Validation with certified reference materials, including fish muscle, liver, phytoplankton, and human hair, confirms its robustness across diverse biological samples. Application to marine trophic chains in Djibouti demonstrated a high trophic magnification factor (TMF = 13.5) for MeHg, emphasizing the severe risk posed by its biomagnification. Additionally, hair samples

from local populations showed a clear correlation between MeHg exposure and seafood consumption patterns, underscoring the method s potential for precise dietary exposure monitoring.
This newly developed technique provides a powerful tool for high-throughput, selective MeHg analysis, supporting comprehensive biomonitoring programs aimed at mitigating public health risks associated with MeHg exposure.

3.26.P-Tu303 A [203Hg]-Metacinnabar Radiotracer to Model the Behaviour and Impacts of Mercury in Decommissioned Subsea Oil and Gas Pipelines
Elisabeth Tondl*, Alexandra Boyd, Tom Cresswell and Francesca Gissi, ANSTO, Australia*
Globally, a large amount of offshore oil and gas infrastructure is reaching end of production life. Subject to local legislative framework, once decommissioned the infrastructure may be left in the ocean or fully removed. Environmental contaminants such as mercury have been found in subsea pipelines at concentrations of up to five orders of magnitude above default sediment quality guideline values. Decisions on leaving infrastructure in situ should consider the behaviour and impact of mercuric species if they are released into the marine ecosystem as the pipes corrode.
Metacinnabar (?-HgS, mercuric sulfide) is a nanoparticulate and poorly soluble form of mercury that has been found in subsea pipelines. Changes to the chemical speciation of the mercury mediated by organisms and sediment redox profiles may promote the formation of methylmercury, which is a neurotoxin that poses serious toxicological risks. The interaction of ?-HgS with seawater, sediments, and biota requires further investigation to ascertain risks posed by mercury if the pipelines are left in situ, then corrode and interact with the ecosystem.
Radiotracing is a technique that enables chemicals to be rapidly tracked and their concentrations to be quantified in model ecosystems under laboratory conditions to elucidate the behaviours of the contaminants. The mercury-203 (203Hg) nuclide is radioactive and can be used to synthesise ?-[203Hg]HgS for use as a model of ?-HgS in subsea pipelines. Literature methods for synthesis of radioactive ?-HgS have different formulations of the radioactive mercury reagent, and lack synthetic repeatability.
This presentation describes the development of a repeatable synthetic method for ? [203Hg]HgS, and presents results of seawater solubility experiments using the radiotracer ? [203Hg]HgS to inform assessment of the risks posed by leaving subsea pipelines that contain ?-HgS in situ.

3.26.P-Tu304 A Perspective on Mercury Methylation Promoted by Particulate Mercury Species in Aquatic Environments
Yong Cai[1]*, Guangliang Liu*[2]*, Yongguang Yin*[3]*, Yuping Xiang*[3]*, Yingying Guo*[3] *and Samuel Sunday Ogunsola*[1]*, (1)Florida International University, Miami, United States, (2)Florida International University, United States, (3)State Key Laboratory of Environmental Chemistry and Ecotoxicology, Research Center for Eco-Environmental Sciences, Chinese Academy of Sciences, China (Mainland)*
Mercury (Hg) is a global health concern due to the long-range intercontinental transport of elemental Hg in the atmosphere and microbial methylation of inorganic Hg to produce highly toxic and bioaccumulative methylmercury (MeHg) in aquatic environments. Mercury methylation is primarily governed by the activities of microbial communities and the availability of inorganic Hg for use by the methylators. Aquatic Hg can be present as dissolved Hg species and more prevalently as particulate Hg forms, including Hg-bearing minerals (e.g., metacinnabar, HgS) and Hg adsorbed on the surface of particles (e.g., iron minerals-bound Hg). Earlier studies have been focused on the bioavailability of dissolved Hg species for Hg-methylating microbes, but a series of our recent studies and others work have increasingly highlighted the role of particulate Hg species in promoting Hg methylation. By reviewing these recent studies, we hereby aim to provide a perspective on the new information regarding the Hg methylation processes involving particulate Hg species. First, some particulate Hg, e.g., HgS nanoparticles, could be directly available for bacterial uptake, serving as Hg substrate entering the cells and thus enhancing Hg methylation. Second, particle surface-adsorbed Hg could be taken up by Hg methylating bacteria co-adsorbed in the proximity through organic ligands released by the bacteria. Third, the close proximity of Hg species and Hg methylating bacteria on the particle surface could produce localized microenvironment with high microbial activity and readily available Hg, hence facilitating Hg methylation.

Disclaimer/Disclosure: This research was partially supported by NSF grant ECS1905239.

3.26.P-Tu305 Mercury in a Low Trophic Level Prey-Predator System: The Freshwater Gammarid *Gammarus pulex* and Juvenile Brown Trout *Salmo trutta*
Poul Bjerregaard*, Department of Biology, University of Southern Denmark, Denmark*

Kinetics for inorganic mercury and methyl mercury were investigated in the freshwater gammarid *Gammarus pulex*. Upon exposure to radioactively labelled inorganic mercury, a steady state concentration factor of approximately 900 was reached in four days. For methyl mercury a steady state concentration factor of approximately 4000 was reached in 7 days. Retention of inorganic mercury and methyl mercury taken up from water over 8 days could be described as bi-exponential decay, with no statistically significant difference between the two mercury forms; 15-25% of the body burden were eliminated within two weeks.
Gammarids fed with food enriched with labelled methyl mercury for 8 days did not eliminate any of the mercury over 10 days; this was also true for gammarids exposed to selenite in both food and water during the elimination period.
G. pulex is an important food item for brown trout.
Juvenile brown trout were collected from 13 different streams on the Island of Funen, Denmark; none of the streams have any known history of mercury contamination. Muscle samples for mercury analysis were dissected out below the dorsal fin of the juvenile trout. The samples were freeze dried and concentrations of total mercury were determined by means of a Milestone Direct Mercury Analyzer.
Average mercury concentrations in the brown trout from the 13 streams varied from 148 to 348 ng Hg/g dry weight with highly significant differences between some of the individual streams. Considering that none of the streams have any known history of mercury contamination this came as a surprise. In one stream, mercury concentrations were determined in 56 fish, and mercury concentrations correlated ($r = 0.53$; $p<0.001$) with the size (and probably age) of the fish.
From each of the two streams with the highest and lowest mercury concentrations, respectively, in the brown trout, fifteen *G. pulex* were collected for analysis of total mercury. The pattern for the brown trout was clearly reflected in the gammarids with average concentrations of 32 and 33 ng Hg/g in the low mercury levels streams and 63 and 76 ng Hg/g in the high level streams.
Mercury is biomagnified from gammarids to brown trout, and the results underline the necessity of elucidating the relative roles of methyl mercury and inorganic mercury in this process. This question is presently under investigation in our laboratory.

3.26.P-Tu306 Mercury Accumulation in Corbicula Clams: Insights into Freshwater Pollution in South Africa

*Chelsea Withfield, **Wynand Malherbe** and Johannes Hendrik Erasmus, Water Research Group, UESM, North-West University, South Africa*

South Africa is a significant global contributor to mercury (Hg) emissions, a critical concern due to its toxicity and severe health impacts on biota. Mercury enters freshwater systems primarily through anthropogenic activities, such as emissions from coal-fired power stations and artisanal gold mining. Bivalves are known to accumulate metals, including Hg, from their aquatic environments, making them potential bioindicators. The freshwater bivalve genus Corbicula is widespread and abundant in South Africa, offering potential for monitoring Hg pollution in freshwater ecosystems. This study sampled 35 sites across northeastern South Africa, detecting Corbicula clams at 15 locations. At each site, a minimum of five clams were collected along with water and sediment samples. Total Hg concentrations in these samples were analysed using a Flow Injection Mercury System. Mercury concentrations in sediment and water correlated with land-use activities, with sites closer to Hg sources showing elevated levels. Notably, environmental Hg concentrations in the Olifants and Inkomati Water Management Areas (WMAs) were higher than those reported 12 years ago. Mercury concentrations in Corbicula tissues exceeded those in corresponding sediment samples, with larger clams exhibiting higher Hg levels, possibly reflecting long-term exposure. A weak negative correlation between water and Corbicula Hg concentrations suggested that bioaccumulation is influenced more by sediment than water. This study underscores the potential of Corbicula clams as effective bioindicators, as Hg accumulation in their tissues offers a more comprehensive representation of bioavailable Hg in aquatic systems than sediment or water samples alone.

3.26.P-Tu307 Mercury in Offshore Oil and Gas Infrastructure; Informing Ecological Risk Assessments for Decommissioning

***Tom Cresswell**[1], Alexandra Boyd[1], Elisabeth Tondl[1], Marie Thomas[2] and Francesca Gissi[1], (1)ANSTO, Australia, (2)AIMS and The University of Queensland, Australia*

Over recent years, there has been an increased global focus on strategies to decommission ageing offshore oil and gas infrastructure. Two main decommissioning options exist: 1) full removal of subsurface and surface facilities for terrestrial waste management or 2) abandonment in situ of assets such as subsea pipelines, moorings, platform jackets. The latter option may provide substantial environmental benefits, including the provision of artificial reef-like structures, that may support commercial benefits through fisheries. However, non-hydrocarbon contaminants on the internal surfaces of production infrastructure,

including mercury, have long been overlooked for in situ abandonment cases.
This presentation provides an overview of recent research in Australia to characterise mercury contamination in subsea gas pipelines (i.e., determine mercury speciation and seawater solubility) and assessments of potential impacts to the marine environment if contaminated infrastructure is left in situ. Examples of using mercury radioisotope tracers to determine mercury bioaccumulation by marine organisms through simplified food webs will be discussed, as well as areas for future research into the long-term fate of mercury in the marine environment from this sector

Track 4. Ecological and Human Health Risk Assessment of Chemicals, Mixtures and Stressors and Risk Mitigation Strategies

4.01.P One Health: Contributions From Environmental Toxicology and Chemistry to This Global Initiative

4.01.P-We315 Metals and Metalloids in Sediment and Aquatic Organisms: Implications for Human Health in Ecuadorian Mangrove Forests

Karla Ajoy[1]*, Frank von Hippel*[1]*, Katiuska Paola Calle Delgado*[2]*, Genesis Portilla*[2]*, Omar Alvarado*[2] *and Carlos Cajamarca*[2]*, (1)University of Arizona, United States, (2)ESPOL, Ecuador*

Mangrove reserves in the Gulf of Guayaquil, Ecuador, are under threat from industrial, agricultural, and aquacultural activities that introduce pollutants into these coastal ecosystems. This study aims to evaluate the concentrations of toxic metals and metalloids in mangrove environments as indicators of overall pollution levels. We collected sediment, fish, and mussels from two reserves: Reserva de Producción Faunística Manglares El Salado (RPFMS) and Refugio de Vida Silvestre Manglares El Morro (REVISMEM). Dietary intake surveys were conducted with residents of Puerto Hondo to perform a human health risk assessment that analyzes the impact on local fishermen. Our analysis revealed that iron (Fe) and copper (Cu) concentrations in sediment samples exceeded USEPA standards. In fish samples, arsenic (As), lead (Pb), and mercury (Hg) levels surpassed USEPA standards, while chromium (Cr), manganese (Mn), and zinc (Zn) levels exceeded FAO guidelines. For mussel samples, only zinc (Zn) levels exceeded both FAO and WHO guidelines. To analyze the data, we normalized and logarithmically transformed the results to conduct a Principal Component Analysis (PCA), which identified the main influencing elements in the sediment, fish, and mussels. This project aims to enhance understanding of the ecological effects of pollutants on these diverse ecosystems, providing a scientific basis to prioritize conservation efforts and inform public policy decisions.

4.01.P-We316 Operational Invertebrate Behaviour Videotracking for Real-Time Wastewater Micropollutant Surveillance

George Ruck[1]*, Arnaud Chaumot*[2]*, Didier Neuzeret*[3]*, Olivier Geffard Pr*[1] *and Jean-Baptiste Aubin*[4]*, (1)INRAE, France, (2)INRAE, France, (3)ViewPoint, France, (4)INSA, France*

As water resources face increasing scarcity, contaminants of emerging concern (CECs) are becoming more prevalent in aquatic systems. Traditional monitoring approaches at wastewater treatment plants (WWTPs) rely heavily on periodic grab sampling and limited bioassays, which are insufficient to capture the complex and dynamic behavior of micropollutants and their temporal discharges. This gap limits our understanding of CEC transfer to and impact on aquatic ecosystems, posing significant challenges to environmental and public health under the One Health framework.

This study introduces an innovative, real-time biomonitoring approach using the multispecies device ToxMate, leveraging avoidance behavior in aquatic invertebrates as a biomarker to characterize micropollution in WWTP effluents. By integrating laboratory and on-site monitoring, we aim to bridge the divide between chemical analysis and ecological relevance.

Our findings involve 1/ Real-World Monitoring: Long-term biomonitoring at urban WWTPs reveals episodic contamination events in effluents, identified through bioactivity signal surges. These events highlight moments of unsuitability for water reuse, alert operators to undetected pollutants, and improve operational efficiency. This real-time monitoring provides critical insights into micropollutant transfer and ecological impact, with implications for optimizing wastewater reuse strategies and safeguarding aquatic ecosystems. 2/ Data-Driven Insights: Laboratory testing of over 40 micropollutants including pesticides, polycyclic aromatic hydrocarbons (PAHs), and pharmaceuticals produced a robust behavioral database through repeated sublethal exposure. Using functional data analysis (FDA), we modeled time series data to develop behavioral fingerprints, enabling multivariate classification techniques such as principal component analysis and supervised learning. This framework enhances the identification of unknown and persistent CECs in real-time alerting systems.

This work underscores the potential of aquatic species as sentinel indicators in wastewater monitoring and exemplifies the One Health vision by connecting environmental biomonitoring to broader public health and ecosystem sustainability objectives. The proposed approach demonstrates how effect-based biomonitoring can complement chemical analysis, improving both detection and mitigation of micropollutants in aquatic environments.

4.01.P-We317 The SPRINT Project - Sustainable Plant Protection Transition: A Global Health Approach

***Vera Silva**[1], Violette Geissen[1], Paula Harkes[1], Esperanza Huerta Lwanga[1], Paul T.J. Scheepers[2] and Martien Graumans[2], (1)WUR, Netherlands, (2)Radboud University, Netherlands*

SPRINT will develop and validate a Global Health Risk Assessment Toolbox to integrate assessments of the impacts of plant protection products (PPP) on ecosystem, plant, animal and human (EPAH) health, using three main attributes for health status: resilience, reproduction/productivity and manifestation of diseases. The goal is integrated risk assessment at the local, regional, national and European level, focusing on different PPP use patterns and detected residue mixtures in contrasting farming systems (conventional, integrated, organic). SPRINT consists of 9 interlinked work packages. The distribution and the impacts of PPP on EPAH health will be evaluated at 11 case study sites (CSS), ten located in diverse agricultural European landscapes, and one in Argentina (soy production for feed for EU market). PPP environmental pathways, and direct (food/feed ingestion) and indirect (air/dust inhalation and dermal uptake) animal and human exposure routes will be assessed to improve current fate, exposure, and toxicokinetic models (e.g. EFSA-FOCUS, BROWSE, BREAM). (Eco)toxicological assays will be performed based on CCS findings, using existing and improved procedures, including alternative testing criteria and new target organisms. Such assays will cover direct and indirect exposure to multiple PPP residues, realistic ranges of PPP concentrations, multi-species scenarios, and short- and long-term time horizons. Modelling of sustainability and cost-benefit analysis at the farm and macroeconomic level will be conducted to derive recommendations for sustainable transition pathways, and a research agenda on PPPs. SPRINT is based on a multi-actor approach with CCS platforms to engage stakeholders and identify respective needs, collaboration along relevant WPs, improving farmer and citizen awareness, joint development of novel management strategies for reduced reliance on PPP use, and creation of an enabling environment for adoption and change.

Disclaimer/Disclosure: The SPRINT Project is funded by the European Union s Horizon 2020 Programme for research & innovation under grant agreement no 862568.

4.01.P-We318 One Health Approach to Addressing Environmental Pollution: Learnings from the Environmental Pollution Programme in South Africa

***Isabella Gosetto**[1], Jason Weeks[1], Nick Rivers-Moore[2] and Jon S. McCosh[3], (1)Joint Nature Conservation Committee, United Kingdom, (2)University of KwaZulu-Natal (UKZN), Durban, South Africa, (3)Institute of Natural Resources, South Africa*

Environmental pollution, along with climate change and biodiversity loss, represents the triple planetary crisis with profound implications for human, animal, and environmental health. These interconnected challenges disproportionately impact vulnerable populations, particularly in low- and middle-income countries (LMICs), where pollution-related health risks are most acute. This motivated the UK s Department for Environment, Food and Rural Affairs (Defra) and the Joint Nature Conservation Committee (JNCC) to collaborate with partners in South Africa on an Environmental Pollution Programme, funded by Official Development Assistance (ODA). The programme embodies a One Health approach by recognising the interdependence of human, animal, and environmental health in tackling pollution. The presentation will reflect on lessons learned from the implementation of ten research projects in South Africa, developed through a collaborative effort involving local communities, scientists, practitioners, and government agencies. These projects span a range of innovative approaches, from nature-based solutions for the protection of springs, to community awareness campaigns on the impact of solid waste, to investigating pharmaceutical pollution risks in freshwater ecosystems. By engaging diverse actors and working at various scales, the programme has underscored the critical interlinkages between pollution and the health of humans, animals, plants, and the broader environment. The presentation will highlight the importance of community-driven solutions, the integration of scientific research with local knowledge, and the vital role of cross-sector collaboration in tackling the complex challenges of environmental pollution, climate change, and biodiversity loss. Insights gained from these projects are relevant for advancing the One Health agenda in LMICs and for informing strategies towards addressing the broader planetary health crisis.

Disclaimer/Disclosure: This project was funded with UK International Development from the UK government.

4.01.P-We319 Life Cycle Tests to Unravel Reproductive and Developmental Effects in *C. elegans*

***Fabio Campos**, Maria D. Pavlaki, Amadeu M.V.M. Soares and Susana Loureiro, Centre for Environmental and Marine Studies (CESAM) & Department of Biology, University of Aveiro, Portugal*

Chemical substances from various sources enter wastewater treatment plants and end up in the environment. Pesticides and pharmaceuticals are usually some of the most found chemical substance classes found in waterbodies and soil. The ubiquitous distribution of these substances raises worldwide concern regarding their potential deleterious effects on non-target organisms and humans. Adverse effects in reproduction output are some of the most concerning ones, where some effort is needed to accurately pinpoint process where the disruption occurs. In order to provide some insights, *Caenorhabditis elegans* figures out as an outstanding animal model to tackle this problem due to its well-known lifecycle and effectively suitable within a One Health approach.

In this study, three chemical substances, found worldwide in waterbodies, were selected: the neurotoxic insecticide cypermethrin, the herbicide MCPA, and the over-the-counter pharmaceutical diclofenac. Different life stages of *C. elegans* life cycle were assessed for each substance to unravel the effects in distinct reproductive stages/processes. The embryotoxicity/neonatal toxicity was evaluated by assessing the hatching rate of exposed *C. elegans* eggs; the developmental toxicity was evaluated by exposing individuals from L1 larvae to egg-laying adults and assessing the total reared offspring; the transgenerational effects (mother-to-progeny) were evaluated by measuring the hatching rate of unexposed eggs obtained from exposed adults. Our results show that all substances affect the reproductive output of *C. elegans* by exerting effects in one or more life stages/reproductive processes. Overall, and surprisingly, the herbicide MCPA was considered as the most toxic tested substance due to the significant observed embryogenic, developmental and transgenerational effects.

The present study's targeted approach provides supporting evidence on the unexpected reproductive effects of chemicals unrelated to their mode-of-action. The results obtained also highlight the potential of *C. elegans* to fill in some gaps in the development of Adverse Outcome Pathways contributing to a more realistic and reliable hazard prediction which can be extended to other organisms and, ultimately, humans, within the One Health approach.

4.01.P-We320 Ecotoxicological Effects of Copper and Pendimethalin at Three Different Temperatures on *Danio rerio* - The Impacts of Climate Changes in One Health World

***Micael Mendes Neves**[1], Ines Domingues[1], Fernando J.M. Goncalves[1] and Ana Marta Goncalves[2], (1)Centre for Environmental and Marine Studies (CESAM) & Department of Biology, University of Aveiro, Portugal, (2)Centre for Environmental and Marine Studies (CESAM) & Department of Biology, University of Aveiro, CFE Centre for Functional Ecology: Science for People & Planet, Marine Resources, Conservation and Technology, Department of Life Sciences, University of Coimbra, Portugal*

Nowadays, the effects of climatic change have been associated with extreme weather events which impact various activities and ecosystems. The exponential increase in world population and the growth in food consumption are placing unprecedented demands on agriculture and natural resources, leading to an intensive use of fertilizers and pesticides to meet food production requirements. Agriculture remains one of the major players in the degradation of aquatic systems. Copper is widely used in biological agriculture practices and is a component of several other pesticides. Copper belongs to the group of transitional essential metals, of vital importance for every organism at low concentrations, becoming toxic at high amounts. Pendimethalin is a widely used herbicide part of the dinitroaniline family. It is used to control annual grass and broadleaf weeds in various crops and residential lawns. These compounds may put at risk the One Health iniiative. Thus, this study aims to determine the combined toxic effect of a range of temperatures (15 °C, 20 °C and 25 °C) and two pesticides (Pendimethalin and Copper) on the embryonic development of Zebrafish (*Danio rerio*). Both compounds were tested using the Fish Embryo acute toxicity Test. At different temperatures, the behavioral impact of the compounds was tested at the end of the tests using a Zebrabox to assess locomotory activity. Embryos were individually exposed in flat-bottom 24-well plates. Low lethality did not allow to assess lethal concentrations. However, it was assessed the effect concentration for hatching (copper) and pericardial edema (pendimethalin). Locomotory activity was significantly impacted by all concentrations of copper at both temperatures. In the case of pendimethalin only the highest concentration impacted the locomotory activity of the exposed embryos. Assays deployed at 15ºC could not be completed for any of the compounds since embryos did not develop due to low temperature, dying after 48 hours. In conclusion, both compounds are toxic to *D. rerio* embryos; however copper is more toxic than pendimethalin. Moreover, our data point to lower toxicity with the increase of temperature for both compounds. In conclusion, both compounds are toxic to *D. rerio* embryos, with copper being more toxic than pendimethalin. Our data indicate that toxicity decreases with increasing temperature. From One Health perspective, it is crucial to study the effects of these contaminants on aquatic life.

4.01.P-We321 Alternative Assays for Routine Toxicity Assessment

Wouter Lanneau[1] *and Kirit Wadhia*[2]*, (1)Microbiotests Inc., Belgium, (2)NOV, United Kingdom*

A substantial number of aquatic toxicity tests exist and are deployed in particular framworks. However, for routine screening of environmental samples and potential chemical formulation investigations, these conventional assays are not practical and hinder expeditious progress. The development of alternative small-scale bioassays referred to as microbiotests has significantly advanced throughput strategies. The microbiotest technology has several advantages in comparison to the traditional tests based on laboratory cultures, especially its independence of the stock culturing burden.
The Daptoxkit is a prime example of a microbiotest that has been effective and has enabled implementation of projects worldwide otherwise not doable and has accelerated the advancement of research & development programs. Microbiotests offer new opportunities for effects monitoring of chemicals and environmental matrices (effluents, leachates, interstitial waters, etc). These can also contribute to increasing the cost efficiency and diagnostic potential of hazard assessment schemes. Use of Daphnia microbiotests is continuing to gather momentum for application in regulatory frameworks. Aquatic microbiotests like Daphtoxkit, invaluable for screening and ranking ecotoxic effects, their intrisic features can contribute to novel applications enabling rapid detection and enhanced throughput. Biological testing, and microbiotesting in particular, will indubitably increase significantly in environmental protection activities in the future. International recognition of biotesting, and more critically owing to limitations in regional testing infrastructure (lack of laboratories and culturing facilities), the implementation scope is globally significantly enhanced to facilitate environmental policies, regulations and guidelines. The imperative need for cost efficiency in environmental assessment continues to fuel the need for R & D concerning microbiotesting.

4.01.P-We322 Of Pigs and Men – Comparing PFAS Toxic Load Patterns in Wild Boar Liver and Human Blood Samples

Tobias Frische, *German Environment Agency (UBA), Section II 2.6 Soil Protection Measures, Germany*

Diffuse PFAS contamination of the environment across the globe has become increasingly evident in the very past years and due to the toxic potential of several well-studied PFAS compounds (e.g. PFOA, PFOS) gives rise to intense scientific attention and public concern. Hence, uptake by and accumulation of PFAS in biota from contaminated environmental media and subsequent food-chain transfer may cause severe long-term adverse effects on human and wildlife populations. Against this background, a comparative data analysis was conducted to explore similarities and differences in PFAS internal exposure and toxic load patterns between humans and wild boars (*Sus scrofa* L.) both being (by origin) omnivorous terrestrial mammalians with however clearly different potential PFAS exposure pathways. First, chemical patterns of the most dominating PFAS measured in human blood and wild boar liver tissue samples were generated from already published data. The analysis focused on samples that are assumed to reflect diffuse background PFAS contamination as well as on samples obtained from a large-scale PFAS hot spot area known for severe contamination of soil and groundwater. Additionally, PFOA equivalents were calculated as toxicological descriptors using the relative potency factor (RPF) approach: The respective content of each of the PFAS targets is scaled relative to the index compound PFOA with subsequent summation of the individual PFOA equivalents yielding a measure of the total toxic load, and the relative contribution (%) of individual PFAS compounds to the summed PFOA equivalents illustrating the toxic load pattern. Long-chain PFAS do accumulate in wild boar livers with following decreasing rank order in relative contribution to the overall toxic load (Frische et al., 2023): PFOS >> PFNA > PFDA > PFUnDA = PFDoDA = PFTrDA; toxic load patterns observed in wild boar liver samples collected in background PFAS contamination areas differ from sample cohorts nearer to the PFAS hot spot. The respective data analysis for human blood samples is still underway, the observed differences of chemical and toxic load patterns between wild boar and human samples will be discussed in the presentation.

4.01.P-We323 Effects of Bisphenols to Amphibians and Fish: An Integrative Approach

Márcio Barreto[1]*, Maria S. Costa*[1]*, Ines Vilarinho*[2]*, Brigite Marques*[2]*, Carla Quintaneiro*[1]*, Marta S. Monteiro*[1]*, Ines Domingues*[1]*, Miguel Oliveira*[1] *and* ***Isabel Lopes***[1]*, (1)Centre for Environmental and Marine Studies (CESAM) & Department of Biology, University of Aveiro, Portugal, (2)Department of Biology, University of Aveiro, Portugal*

Plastic contamination poses a major environmental issue, primarily due to improper disposal and landfill runoff, which have led to the ubiquitous presence of plastics in aquatic environments. Alongside plastics themselves, intentionally added substances like plasticizers and flame-retardants can leach into the surrounding environment as they are not covalently bound to the plastic matrix. Characterizing the hazards of these substances, especially plasticizers such as bisphenol A (BPA) analogues, is critical. These analogues may be as toxic or even more toxic than BPA, and their environmental presence is expected to increase due to the demand for "BPA-free" in commercialized products and BPA restrictions in food-contact materials. This study aimed at a comparative assessment of the toxicity of BPA and bisphenol AF (BPAF) for amphibian and fish models, namely for: *Xenopus laevis* cell lines, embryos and tadpoles, and for *Danio rerio* embryos and larvae. To attain this objective, 72-h cytotoxic assays were conducted with the X. laevis A6 cell line, where cell viability was assessed through the MTT viability assay. Embryos of *X. laevis* and *D. rerio* were exposed for 96-h and 120-h (respectively) to assess mortality, occurrence of malformations and heart rate. Additionally, tadpoles and zebrafish larvae were exposed to sublethal concentrations for 48-h to analyse key components for locomotor behaviour with an automated tracking system. Obtained results suggest that BPAF was more toxic to both *X. laevis* embryos and A6 cell line than BPA. Moreover, *D. rerio* embryos also exhibited a similar trend, where BPAF presented a lower 120h-EC50 (mortality and malformations) than BPA. Furthermore, BPAF also showed to highly affect heart rate compared to BPA for *D. rerio* embryos suggesting higher toxicity of this BPA analogue for this species life stage. These findings highlight the need for an extensive assessment on bisphenol analogues, like BPAF which exhibits higher toxicity compared to BPA. The increased use of BPA-free products in response to growing concerns to BPA s environmental impacts may inadvertently lead to a greater exposure to these potentially more harmful analogues. This study emphasizes the importance to rethink material safety standards and the need for a robust and comprehensive risk assessment of all bisphenol derivatives, given their widespread use and applications of these compounds, potentially harming both human and environmental health.

4.02 Addressing Regulatory Gaps in Polymer Risk Assessment: Advances in Testing, Novel Test Methods, and Environmental Impact Evaluations

4.02.T-01 Leveraging Increased Microbial Cell Concentrations to Assess the Biodegradability of Water Soluble and Water-Dispersible Polymers in Laboratory Tests
Glauco Battagliarin[1], *Kathleen McDonough*[2], *Jan Robinson*[3], *Andrea Brunswik-Titze*[4], *Vurtice C. Albright III*[5], *Marlies Bergheim* [6], *Jared Bozich*[7], *Mickael Cregut*[8], *Soumya Daturpalli*[9], *Christian Kastner*[6], *Andrea Jacobi*[10], *Georg Kreutzer*[11], *Arturo Mendoza*[12], *Jennifer Menzies*[13], *Silvia Michelucci*[14], *Yash Parulekar*[15], *Meera Raghuram*[16], *Nathalie Vallotton*[17] *and Nils Wedler*[18], *(1)Research Biopolymers, BASF SE, Germany, (2)Procter & Gamble, Mason, United States, (3)A.I.S.E., Brussels, Belgium, (4)Hydrotox GmbH, Germany, (5)The Dow Chemical Company, United States, (6)Henkel AG & Co, Germany, (7)IFF, United States, (8)SYENSQO, BAULKHAM , Australia, (9)BASF Se, Germany, (10)Evonik Operations GmbH, Germany, (11)RAPS, Givaudan, Switzerland, (12)Environmental, RAPS Analytical, Givaudan, Switzerland, (13)Procter & Gamble, United States, (14)Ecopol, Italy, (15)MonoSol, Merrillville, United States, (16)Lubrizol, United States, (17)Dow Europe GmbH, Switzerland, (18)Reckitt, Germany*
Water-soluble and water-dispersible polymers are essential ingredients in home and personal care formulations, offering unique benefits in terms of performance and sustainability. For polymeric materials, regulations world-wide are rapidly developing with greater focus on the assessment of their degradability in applications leading to environmental exposure. This shift emphasizes the need to identify and critically evaluate testing guidelines for assessing biodegradability of polymeric materials.
OECD test guidelines were developed to assess the biodegradability of discrete low molecular weight, water soluble substances, making it essential to validate, adapt or develop new protocols for polymers. In contrast to low molecular weight substances, and owing to their macromolecular nature, polymers require an extracellular enzymatic cleavage before the degradation products can be assimilated by microbes for metabolisation. This extra step may result in intrinsically longer times for degradation and a disproportionately larger number of polymers that fail to meet the passing thresholds associated with OECD screening tests. In addition, the presence and activity of extracellular enzymes and microbes producing them are critical for assessing polymer biodegradability in laboratory methods.
In this study, we investigate in an interlaboratory effort the potential of modifying screening biodegradation tests by increasing the concentration of inoculum (sludge) to assess the biodegradation of

water-soluble polymers. We explore various polymers relevant for home and personal care formulations with differing chemistries, molecular weights, and degrees of substitution, including polyethylene glycol, carboxymethyl cellulose, cationically modified guar gum, and polyvinyl alcohol. A direct comparison is made between standard OECD 301 B and F testing protocols and modified conditions with increased microbial abundance (both concentration and in totality via increased test volumes) to test chemical ratios. For both protocols, testing times have been extended to reach biodegradation plateau.
Our investigations highlight the potential of methods leveraging increased cell concentrations and extended test times for more accurate and reliable determinations of the biodegradability of water-soluble polymers. Furthermore, our findings highlight strengths and limitations of existing OECD 301 test methods to investigate water-soluble polymers.

4.02.T-02 Moving Biodegradation Testing of Water-Soluble Polymers Closer to Environmentally Realistic Scenarios

Aaron Kintzi[1], *Soumya Daturpalli*[2], *Glauco Battagliarin*[3] *and Michael Zumstein*[1], *(1)University of Vienna, Centre for Microbiology and Environmental Systems Science, Division of Environmental Geosciences, Austria, (2)BASF SE, United States, (3)BASF SE, Limburgerhof, Germany*
Water-soluble polymers (WSPs) are essential for the performance of many home and personal care products. Being disposed down-the-drain after use in many applications, biodegradability in wastewater systems is a desirable feature of sustainable WSPs. To support the development and regulation of biodegradable WSPs, scientifically valid and economically viable biodegradation test methods are essential. Existing biodegradation testing guidelines, such as the OECD 301 series, were developed for small molecules, warranting a critical assessment of their applicability to WSPs, which we aim to contribute to through this study.
In brief, we explored potential test modifications by evaluating the impact of individual and combined protocol variations of the OECD 301 guidelines on the biodegradation of WSPs by wastewater microbiomes. We incubated a selected set of WSPs (e.g., the polyamino acids polylysine and polyaspartic acid, polyethylene glycol, and polyvinyl alcohol) and low-molecular-weight reference substrates with wastewater microbiomes, quantified biodegradation with respirometric methods, and conducted complementary enzyme activity assays and microbial community analyses.
Key protocol variations involved (i) washing and aerating microbial inoculum before WSP addition, (ii) pre-incubating WSPs with filter-sterilized untreated wastewater, and (iii) examining the effects of WSP concentration. Most importantly, combined protocol variations showed substantially accelerated biodegradation of the tested poly(amino acids) compared to the standard protocol. As these variations did not significantly affect the biodegradation of low-molecular-weight reference compounds, our findings indicate that the observed effects are specific to polymers. Building on these results, we are currently working with complementary methods to further move laboratory-based WSP biodegradation testing towards realistic scenarios. Together, our contribution reveals promising biodegradation data for poly(amino acid)s and highlights challenges and opportunities for WSP biodegradation testing.

4.02.T-03 Phys-Chem Challenges in Regulatory: Water Solubility and Octanol/Water Partition Coefficient

Joachim Venzmer, *Evonik Operations GmbH, Research Interfacial Technology, Germany*
Some methods which were originally developed for low molecular weight, non-amphiphilic molecules are hardly applicable to surfactants and amphiphilic polymers. This results in highly questionable values, but if they are below some threshhold, they did not raise any alarm and were accepted without questioning their validity. As long as the results do not cause any negativ consequences, this could be ignored but what to do if this was not the case?
Even supposedly easy parameters such as solubility in water (OECD TG 105) are challenging: For surfactants, (A) there is no saturation concentration, and (B) above the so-called Critical Micelle Concentration (CMC), they form micelles of few nm in size. Unfortunately, there is a terrible misconception: Micelles have been described as not bioavailable, insoluble hydrophobic droplets of surfactants completely ignoring the rapid (timescale µs to ms) exchange between the monomers in the bulk phase and the molecules within the micelles. Therefore, the factual solubility of surfactants as aggregates is orders of magnitude higher than the CMC.
The octanol/water partition coefficient logKow is a measure of hydrophobicity/hydrophilicity which has also never been meant to be used for surface-active materials; it is used to predict the (eco)toxicological consequences. One accepted option is a calculated value based on CMC and the solubility in octanol. The latter is determined by OCED TG 105 and replacing water by octanol. Since the method is based on visual observation, the determination of the solubilities in octanol leads to results which are several orders of

magnitude overestimated: Coarse emulsions look crystal clear and are mistaken as solubility, because the difference in refractive index between octanol and the sample is often rather low. As a consequence, these values for logKow are much too high and do not reflect the properties of the substance tested. Phys-chem data such as solubility and logKow should be a measure of the properties of a substance tested. If, however, the methods to be used are hardly applicable to surface-active materials, there should be an agreement to which extent science should prevail over taking non-applicable technical guidelines literally.These three most pressing issues are currently being addressed by the CESIO Working Group Test Methods of Surfactants (TMS) and the Phys-Chem Workstream of the recently established ECETOC Polymer Analytics Task Force.

4.02.T-04 Anticipating the Implementation of Polymer REACh: Exploring the Technical Challenges for Polymers in OECD Test Guidelines for Solubility and (Eco-)Toxicity Tests

Simon Luderwald[1], Friederike Luenne[2], Denis Botin[2], Nora Hartner[2], Naveed Honarvar[1], ***Patrick Baudy-Groh***[3] *and Susanne Noreen Kolle[1], (1)BASF SE, Experimental Toxicology and Ecology, Germany, (2)BASF SE, Analytical and Material Science, Germany, (3)Experimental Toxicology and Ecology, BASF SE, Germany*

As part of the European Green Deal and the Chemical Strategy for Sustainability, it is anticipated that REACH registration will be expanded to include polymers, incorporating data requirements for analytical, ecotoxicological, and toxicological assessments, primarily based on established OECD test guidelines (TGs). These TGs have been validated for small molecules, and their technical applicability and predictive capabilities have not been thoroughly assessed across the entire spectrum of chemical substances, especially polymers were not included. Unlike small molecules, polymers are inherently characterized by e.g. distribution of chain lengths, different end-groups, and unique architectures. Therefore, the technical applicability of the existing TGs on polymers is potentially limited and involves the risk of generating unreliable data impacting risk assessments. In our study, we evaluated the technical applicability of several OECD TGs using a set of 17 different polymers. The determination of solubility and extractability was based on OECD TG 120 for polymers, however, the sample preparation procedures outlined are not universally applicable to all polymer types. Our assessment also included various test systems determining (eco-)toxicological effects: OECD TG 202 (Daphnia sp. acute immobilization test), OECD TG 487 (in vitro mammalian cell micronucleus test), and OECD TG 439 (in vitro skin irritation: reconstructed human epidermis test method).
The development of standardized methods for analytical, ecotoxicological, and toxicological evaluations is crucial, especially for complex materials like polymers. In this context, we highlight the challenges of applying existing OECD test guidelines to polymers and propose alternative approaches that may be more appropriate.

4.02.P-We324 Navigating the Limitations of SEC: Strategies for Improved Polymer Analysis in Regulatory Frameworks

Timo F. Beskers[1] and ***Jana Falkenhagen***[2]*, (1)BASF SE, Germany, (2)BAM Bundesanstalt fur Materialforschung und -prufung, Germany*

Polymers, composed of repeating units called monomers, exhibit a diverse range of properties, with molecular weight distribution (MWD) being particularly important for regulatory risk assessments. Size exclusion chromatography (SEC), or gel permeation chromatography (GPC), is the primary technique for MWD characterization, as detailed in OECD guidelines 118 and 119, along with DIN and ISO standards. However, SEC faces significant shortcomings that complicate the accurate determination of MWD and oligomer content. These limitations include the insolubility of certain polymers, crosslinking, and ultra-high molecular weight characteristics, which can exceed SEC's separation capabilities. The presence of salts or modifiers can further interfere with oligomer content determination, and the availability of appropriate SEC columns and calibration standards limits comparability across laboratories.
To enhance SEC's reliability and applicability within regulatory frameworks, innovative methods and strategies are essential. Proposed solutions involve new sample preparation techniques, advanced data interpretation methods, and the establishment of standardized methodologies to promote harmonization. This is especially crucial in light of the expected Polymer REACh (PREACh) legislation, which aims to regulate polymer registration and risk assessment within the European market.
Given the anticipated complexity of the registration process, which requires extensive data generation, proactive strategies are needed to address SEC's challenges. Currently, there are no viable alternatives for oligomer content determination, and the unique properties of polymers often necessitate tailored analytical approaches. Without new methodologies and guidelines, the polymer registration process could become burdensome and costly, jeopardizing important products and markets in the EU.
Key areas for improvement include extending existing norms to cover a broader range of solvents,

addressing high error margins in oligomer content determination, establishing harmonized approaches for dealing with side components, and providing clarity on measuring partially soluble polymers. In conclusion, addressing SEC's limitations through the development of comprehensive guidelines and harmonization is critical for ensuring accurate and efficient polymer analysis, ultimately facilitating smoother registration processes.

4.02.P-We330 Next-Generation Biodegradation Testing for the PLF Market: Re-envisaging Biodegradation Standards Tests

***Nick W. Johnson**[1], Sam B.H. Patterson[2], Trevor Hinchcliffe[2], Filipe Vilela[1] and Humphrey H.P. Yiu[1], (1)Heriot-Watt University, United Kingdom, (2)Impact Solutions, United Kingdom*

Polymers in liquid formulation (PLFs) represent a significant proportion of the polymer market ($125.2 billion) and are vital to a diverse range of industries including personal care, paints and agriculture. The addition of PLFs are required to alter the chemical and rheological properties of liquid formulation products to improve longevity, resistance to degradation, and overall product performance. However, due to a change in current EU REACH regulations, Article 138 (2), requiring the registration of polymeric substances, there is a requirement to replace existing PLFs with more sustainable, biodegradable alternatives in a market which is profoundly reliant on petrochemical feedstocks. However, the development of novel biodegradable polymers is hindered by existing biodegradation standard testing, which is time consuming, not fit-for-purpose and does not provide the data required by the industry. To address this concern, Impact Solutions are developing advanced solutions for biodegradation testing aimed at the PLF market. Initially, we are developing a colorimetric assay to assist industry in the preliminary development stage. This 96-well plate assay works in line with current OECD standard biodegradation testing and will provide a high-throughput in-house method to screen vast numbers of potential biodegradable polymers. Additionally, in a collaboration with Heriot-Watt University, we are looking to build on previous work on the enzymatic depolymerisation of polycaprolactone to conduct biodegradation studies on a fluidised bed reactor. By providing continuous data analysis, bespoke advanced datasets can be generated and customised to assess how the polymer is broken down in the environment. These datasets, which are currently not accessible using current standard tests, could be subsequently employed to provide vital information on the environmental fate and ecotoxicity of a polymer and potentially pave the way to generate biodegradation simulation models in line with models which are currently available to small molecules.

Disclaimer/Disclosure: N.W.J acknowledges UK Innovate for the award of an Knowledge Transfer Programme (KTP) (10113448) between Impact Solutions and Heriot-Watt University.

4.02.P-We335 Innovating on Polymer Fegradation: Making Two Ends Meet

***Nathalie Vallotton**[1], Ben Reiner[2], Ligeng Yin[3], Vurtice C. Albright III[4] and Lyndsay Leal[3], (1)Dow Chemical Company, Switzerland, (2)Core R&D, Dow Chemical Company, Collegeville, PA., United States, (3)Home and Personal Care R&D, Dow Chemical Company, United States, (4)The Dow Chemical Company, Midland MI, United States*

Polymers play a pivotal role in modern society by providing a multitude of technical functionalities in materials and products. They represent a vast and diverse aspect of the chemical space, often characterized by medium to very high molecular sizes and various functionalities. For polymers emitted down the drain, ultimate degradability becomes a favourable property. Yet, assessing the environmental fate of polymers poses scientific challenges, primarily due to their high molecular weight, which leads to low bioavailability impacting for example uptake in biodegradation studies.
In line with their emission routes, polymers used in Home and Personal Care products are evaluated for their biodegradation potential. However, the domain of applicability of standardized test guidelines, such as those from the OECD, does not include polymers. Therefore, the innovation of new materials faces two main challenges. The first is the need to accelerate the development of screening methods to inform product development, while the second is aligned to the need for the adaptation of standardized test methods to widen the applicability domain to polymers. In this presentation, we delve into methodologies for evaluating the biodegradation of polymers in aqueous systems during product development by use of screening and modified test methods.
At early stages of development, combining enzymatic assays with analytical techniques like 1H NMR spectroscopy enables the characterization of changes in structural features. Additionally, candidate polymers are evaluated using standard or modified OECD biodegradation screenings studies. Adaptions including the extension of the test durations, are valuable approaches in comparing the biodegradation polymers with similar structural properties.

4.02.P Addressing Regulatory Gaps in Polymer Risk Assessment: Advances in Testing, Novel Test Methods, and Environmental Impact Evaluations

4.02.P-We324 Navigating the Limitations of SEC: Strategies for Improved Polymer Analysis in Regulatory Frameworks

*Timo F. Beskers[1] and **Jana Falkenhagen**[2], (1)BASF SE, Germany, (2)BAM Bundesanstalt fur Materialforschung und -prufung, Germany*

Polymers, composed of repeating units called monomers, exhibit a diverse range of properties, with molecular weight distribution (MWD) being particularly important for regulatory risk assessments. Size exclusion chromatography (SEC), or gel permeation chromatography (GPC), is the primary technique for MWD characterization, as detailed in OECD guidelines 118 and 119, along with DIN and ISO standards. However, SEC faces significant shortcomings that complicate the accurate determination of MWD and oligomer content. These limitations include the insolubility of certain polymers, crosslinking, and ultra-high molecular weight characteristics, which can exceed SEC's separation capabilities. The presence of salts or modifiers can further interfere with oligomer content determination, and the availability of appropriate SEC columns and calibration standards limits comparability across laboratories.

To enhance SEC's reliability and applicability within regulatory frameworks, innovative methods and strategies are essential. Proposed solutions involve new sample preparation techniques, advanced data interpretation methods, and the establishment of standardized methodologies to promote harmonization. This is especially crucial in light of the expected Polymer REACh (PREACh) legislation, which aims to regulate polymer registration and risk assessment within the European market.

Given the anticipated complexity of the registration process, which requires extensive data generation, proactive strategies are needed to address SEC's challenges. Currently, there are no viable alternatives for oligomer content determination, and the unique properties of polymers often necessitate tailored analytical approaches. Without new methodologies and guidelines, the polymer registration process could become burdensome and costly, jeopardizing important products and markets in the EU.

Key areas for improvement include extending existing norms to cover a broader range of solvents, addressing high error margins in oligomer content determination, establishing harmonized approaches for dealing with side components, and providing clarity on measuring partially soluble polymers. In conclusion, addressing SEC's limitations through the development of comprehensive guidelines and harmonization is critical for ensuring accurate and efficient polymer analysis, ultimately facilitating smoother registration processes.

4.02.P-We325 Error Margins in the Determination of Molar Mass and Oligomer Content of Polymers

***Jana Falkenhagen**[1], Jan-Hendrik Arndt[2], Timo F. Beskers[3], Alexander Eifert[4], Sabine Gaul[5], Sabine Keune[6], Ron A.H. Peters[7], Sebastian Schmiedt[8] and Alexander von Tesmar[9], (1)BAM Bundesanstalt fur Materialforschung und -prufung, Germany, (2)Fraunhofer LBF, Germany, (3)BASF SE, Germany, (4)Wacker Chemie AG, Germany, (5)Clariant Innovation Center, Germany, (6)Evonik Operations GmbH, Germany, (7)Uni Amsterdam, Van 't Hoff Institute for Molecular Sciences, Netherlands, (8)Eurofins Agroscience Services EAG Laboratories GmbH, Germany, (9)Currenta GmbH & Co. OHG, Germany*

Size exclusion chromatography (SEC) is still the method of choice for determining the molar mass and molar mass distribution of macromolecules.

It is a liquid chromatographic technique that separates molecules based on their size, respectively their hydrodynamic volume using a porous stationary phase that allows smaller molecules to pass through the pores while excluding larger molecules. The chromatogram from the size separation can be calibrated using polymers of known molar mass resulting in a relative molar mass distribution curve. From this distribution curve molar mass averages and the oligomer content (percentage of peak area smaller than 1000 g/mol and 500 g/mol) of polymers can be derived.

The determination of oligomer content is important, because it is often used in regulatory contexts as a measure of small, mobile and potentially more toxic parts of the polymer. Polymer regulations are of increasing political and social importance. Regulations often set very narrow limits.

SEC has rather large error margins of 10-20% for the molar mass determination performed in different laboratories or on different instruments. These variances are well known to all experts and users and have been investigated in several round robin tests in the past. These resulted in DIN and ISO standards which, in our opinion, no longer meet today's requirements.

As far as we know, the margins of error in determining oligomer content have not yet been investigated. It is expected that the variation will be rather high. This is because it depends on many factors related to the experimental conditions (column sets used, solvent, temperatures, sample preparation) on the one hand, and the data evaluation mechanisms (choice of baseline and peak limits) on the other.

In order to actually measure the error margins and to support this with actual data a round robin test has been performed from June to November 2024 with approx. 40 participating laboratories.
Three different solvents were selected, namely THF, DMAc or DMF and water.
The samples were selected together with all the experts, taking into account a wide range of practical aspects far from narrowly distributed standards: e.g higher distribution range, reduced solubility, included side components, copolymers and dispersions with gel content.
In this contribution we will present the detailed concept of this round robin test and first results.

4.02.P-We326 An Algorithm to Address Side Components in SEC Chromatograms of Polymers for Regulatory Purposes

*Timo F. Beskers[1], Bastiaan B.P. Staal[1], **Friederike Luenne**[1], Paul-Albert A. Schneide[1] and Gabriel Vivo-Truyols[2], (1)BASF SE, Germany, (2)Tecnometrix, Spain*

Size Exclusion Chromatography (SEC) is a crucial method for analyzing the molecular weight distribution (MWD) and oligomer content in polymers. Accurately determining oligomer content is vital for regulatory risk assessments concerning polymers and is a fundamental requirement for polymer substance registration in various countries, including the anticipated revisions to REACh in the EU. SEC operates by separating molecules according to their size in solution, specifically their hydrodynamic volume, which makes it an entropic process that is not specific to any chemical characteristics.
However, the presence of side components in the sample presents significant challenges for SEC analysis. To achieve accurate results, SEC measurement conditions must be optimized for the specific polymer, requiring a careful balance of polarity among the sample, solvent, and stationary phase. This is essential to avoid enthalpic interactions that could disrupt the SEC separation mechanism. Side components can vary in chemical nature and polarity; if they share similar polarities with the polymer, they may elute within the calibrated SEC range, leading to overlap with polymer signals and complicating the determination of oligomer content and MWD. Side components with differing polarities may elute outside the SEC chromatogram or may go undetected if they are insoluble in the solvent.
Consequently, the oligomer content derived from SEC cannot fully encompass all low molecular weight species present, nor does it consistently isolate the polymer oligomer content due to its lack of specificity. Analyzing real-world polymer products, which often contain impurities, is particularly challenging due to overlapping peaks. If the concentration of a side component is known and measurable, peak subtraction can provide a viable solution for analysis. Determining the exact concentration is often challenging and time consuming.
Here we will present a newly developed algorithm, which enables rapid and straightforward estimation of SEC results for the pure polymer in a mixture when only the SEC chromatograms of both the polymer with side component and the side component alone are available. This provides a fast and cost-effective solution to decide if a regulatory limit is met, even when side components are present.

4.02.P-We327 How Applicable are Existing Methods for the Determination of Adsorption/Desorption of Polymers – Application and Comparison of Test Guidelines OECD 106 and OECD 121

***Sebastian Schmiedt** and Paul Bendig, Eurofins Agroscience Services EAG Laboratories GmbH, Germany*

The ecological hazard and risk for small molecules and products thereof is assessed among other things with the help of several physico-chemical properties. With the upcoming development and growing concerns in the use of polymers also the demand for these data for polymers is rising.
There are analytical methods described in technical guidance documents (e.g. OECD TG 100 series), which were developed for small molecules, but are not yet tested for applicability or are extended for the analysis of polymers. In general, additional research is needed to address this issue.
One of the relevant properties is the adsorption and desorption to soil or sludge, which is used e.g. to estimate the behavior in modelling the percolation to ground water or behavior in wastewater treatment plants.
The aim of the project was to compare the OECD tests 106 and 121 using well defined polymer samples in regard of applicability and possible limitations. For this purpose, the differences in the feasibility and outcome of the results are evaluated when using both test guidelines. In additions challenges such as low water solubility or analysis of high molecular weight substances could be addressed.

4.02.P-We328 Current Plastic Definitions and the Impact on Hazard Assessment of Dispersed Persistent Polymers in the Regulation of Chemicals

***Malgorzata Wilczynska**, James Brown, Claire Phillips, Carl Clarke, Nicola Geary, Anna Sypniewska-Huk, Nathan Read and Freya Mickleburgh, Centre for Environment, Fisheries and Aquaculture Science (Cefas), United Kingdom*

Plastics are defined as solid particles which are water insoluble and are composed of mixtures of synthetic polymers and functional additives such as UV stabilizers, antioxidants, and heat stabilizers specifically intended to make them durable and persistent in the environment. The updated Europe Union (EU) regulation considers the fluidity test as one of the criteria that confirms the substance status as a plastic. Numerous polymers that are nonbiodegradable in the environment are produced in the form of colloids or gels that previously didn t fall under the plastic definition as they weren't classed as solid . The application areas for polymer colloids are diverse, including their use as binders in fabrics and paper coatings, synthetic rubbers, paints, adhesives, toughened plastics, catalytic supports, flow modifiers and resins. Global efforts to control plastics and their associated chemicals are beginning to be embraced; however, plastic colloids are not as heavily scrutinised, despite some substances being highly persistent. Those semiliquid substances can precipitate in the marine water and become entrained in the sediment of disperse or as a gel could enter the food chain.
Future actions in plastic regulations should build on existing knowledge and avoid the duplication of effort by identifying and harnessing national, regional, and global regulation.
Regulatory instruments are a major tool for controlling and phasing out chemicals of concern therefore additional review of plastic definition should be conducted in the context of the physical state and persistence of substances. Chemicals are infinitely complex and there is need for improved characterisation and tighter controls for persistent chemicals. This presentation aims to identify knowledge gaps and potential areas of concern with respect to the aquatic environment and offers solutions with respect to the application of existing regulatory frameworks for future work to reduce the impact on the environment.

4.02.P-We329 Assessing Bioavailability Water-Soluble Polymers: Conceptual and Historical Considerations

Kristin Connors *and Corie Ellison, The Procter and Gamble Company, United States*

Historically, water-soluble polymers have been considered of low hazard to both humans and the environment since they have a high molecular weight and are often assumed to have poor/negligible bioavailability. In the 2024 ECHA report on Key Areas of Regulatory Challenge, ECHA noted that "high molecular weight polymers can no longer be considered innocuous by default" and further emphasized the need to build a fundamental understanding of polymer bioavailability. Bioavailability is a critical consideration in both human and environmental hazard and risk assessments, including in the assessment of bioaccumulation potential. Several physiochemical properties are known to limit bioavailability including molecular weight, molecular diameter/bulkiness, lipophilicity, and ioniziation. In this presentation, we will provide a conceptual overview of bioavailability as it relates to relevant routes of exposure for both human and environmental hazard assessments (e.g., oral, dermal, inhalation [lungs, gills]). Experimental approaches used to characterize bioavailability will be discussed (e.g., modeling approaches, CaCo2, Ussing chambers, etc). We will summarize the historic evidence for low bioavailability of high molecular weight water-soluble polymers, highlight key uncertainties, and provide recommendations for future research needs.

4.02.P-We330 Next-Generation Biodegradation Testing for the PLF Market: Re-envisaging Biodegradation Standards Tests

Nick W. Johnson[1]*, Sam B. H. Patterson*[2]*, Trevor Hinchcliffe*[2]*, Filipe Vilela*[1] *and Humphrey H. P. Yiu*[1]*, (1)Heriot-Watt University, United Kingdom, (2)Impact Solutions, United Kingdom*

Polymers in liquid formulation (PLFs) represent a significant proportion of the polymer market ($125.2 billion) and are vital to a diverse range of industries including personal care, paints and agriculture. The addition of PLFs are required to alter the chemical and rheological properties of liquid formulation products to improve longevity, resistance to degradation, and overall product performance. However, due to a change in current EU REACH regulations, Article 138 (2), requiring the registration of polymeric substances, there is a requirement to replace existing PLFs with more sustainable, biodegradable alternatives in a market which is profoundly reliant on petrochemical feedstocks. However, the development of novel biodegradable polymers is hindered by existing biodegradation standard testing, which is time consuming, not fit-for-purpose and does not provide the data required by the industry.

To address this concern, Impact Solutions are developing advanced solutions for biodegradation testing aimed at the PLF market. Initially, we are developing a colorimetric assay to assist industry in the preliminary development stage. This 96-well plate assay works in line with current OECD standard biodegradation testing and will provide a high-throughput in-house method to screen vast numbers of potential biodegradable polymers. Additionally, in a collaboration with Heriot-Watt University, we are looking to build on previous work on the enzymatic depolymerisation of polycaprolactone to conduct biodegradation studies on a fluidised bed reactor. By providing continuous data analysis, bespoke advanced datasets can be generated and customised to assess how the polymer is broken down in the environment. These datasets, which are currently not accessible using current standard tests, could be subsequently employed to provide vital information on the environmental fate and ecotoxicity of a polymer and potentially pave the way to generate biodegradation simulation models in line with models which are currently available to small molecules.

Disclaimer/Disclosure: N.W.J acknowledges UK Innovate for the award of an Knowledge Transfer Programme (KTP) (10113448) between Impact Solutions and Heriot-Watt University.

4.02.P-We331 Risk Assessment of Water-Soluble Cationic Polymers Reflecting Realistic Environmental Conditions

Shintaro Enoki[1]*, Yuto Amano*[2]*, Yasuaki Inoue*[2]*, Hiroshi Honda*[2]*, Takahiro Suzuki*[3]*, Akiyo Kameyama*[2] *and Masayuki Yamane*[2]*, (1)Kao Corporation, Japan, (2)Kao Corporation, Japan, (3)Kao Corporation, Tokyo, Japan*

The assessment of the ecological impacts of polymers is important due to increased regulation and public concern. Water-soluble cationic polymers used in cosmetics and personal care products have raised concerns due to their high toxicity to aquatic organisms and poor biodegradability. On the other hand, several studies suggest that cationic polymers adsorb to activated sludge at wastewater treatment plants (WWTPs) or organic matter in rivers. Therefore, the environmental concentration of cationic polymers is expected to be low and may have a small impact on the ecosystem. However, there are few studies of refined ecological risk assessments considering the removal of cationic polymers in WWTPs and their adsorption on organic matter.

In this study, exposure and hazard assessments were conducted for water-soluble cationic polymers, polyquaternium-6 (PQ-6) and PQ-7, and the risk quotients (RQs) of the polymers in Japan were determined. Daphnids and algae toxicity tests were conducted under both standard OECD Test Guideline (TG) 201 and 202 conditions and in the presence of humic acid. Subsequently, toxicity mitigation factors were calculated. The removal rate in the WWTPs was estimated by quantifying the adsorbed substances to activated sludge based on the OECD TG 314B.

The results indicated toxicity mitigation with the addition of humic acid, suggesting that the toxic effects under realistic environmental conditions are reduced compared to those observed under standard OECD test conditions. Furthermore, rapid adsorption behavior on activated sludge was confirmed, suggesting that the test substances are almost completely removed in the WWTPs. Finally, we conducted a risk assessment based on the distribution volume of these polymers within Japan. By applying the new factor obtained in this study, the RQs for PQ-6 and PQ-7 were determined to be below one, indicating no significant concern for the aquatic environment.

This study provides novel insights into the toxicity and exposure profiles of PQ-6 and PQ-7, bridging the data gaps between standard test conditions and environmentally realistic conditions. Our risk assessment of cationic polymers will further advance the discussion on the appropriate use of polymers and the risk assessment reflecting realistic environmental conditions.

4.02.P-We332 Polyvinylpyrrolidon Speeds Up and Increases Methane Production from Freshwater Sediments

Alexander Feckler[1]*, Eric Bollinger*[2]*, Alexandra Unik*[2]*, Sabine Filker*[2]*, Zacharias Steinmetz*[2]*, Christian Pflicht*[2] *and Mirco Bundschuh*[2]*, (1)Institute for Environmental Sciences (iES Landau), University of Kaiserslautern-Landau (RPTU), Germany, (2)University of Kaiserslautern-Landau (RPTU), Germany*

Synthetic hydrophilic polymers, such as polyvinylpyrrolidone (PVP), are extensively used for a wide range of applications, including household cleaning, personal care products, wastewater treatment, and agriculture. After their use, these polymers can enter freshwater systems. Due to their polar or charged functional groups, they dissolve easily in water, making them bioavailable to freshwater and sediment-associated organisms, potentially disrupting ecological processes. Despite these hazards, the environmental impacts of synthetic hydrophilic polymers remain largely unknown, especially for sediment-associated organisms. To address this knowledge gap, we incubated freshwater sediment under anaerobic conditions with PVP at four concentrations (0, 0.5, 50, and 5000 mg/L) for 56 days, assessing methanogenesis as a key ecosystem process. Weekly measurements of methane (CH4) in the headspace of the test systems showed that CH_4 production speed and total CH_4 production increased by up to 6% and 20%, respectively, at 5000 mg/L, a concentration already observed in treated wastewater. The mechanisms driving these results may be two-fold: first, exposure to PVP could have altered the bacterial community composition, potentially affecting the functional profile of methanogenic microbes. This hypothesis is currently being investigated using metabarcoding of the archaeal and bacterial 16S rRNA genes. Second, PVP itself might serve as a carbon source for sediment-associated microbial communities, increasing CH_4 production. Although the exact mechanisms remain to be uncovered, our study suggests that synthetic hydrophilic polymers can impact the environment by contributing to greenhouse gas emissions through altered methanogenesis in freshwater ecosystems.

4.02.P-We333 (Semi-)Quantitative Analysis of Polyamide 6 Oligomers in Multiple Water Samples using LC-HRMS: Evidence for the Presence of Polymer Derivatives in Drinking Water and Domestic Sewage

Kailin Shen[1] *and Junho Jeon*[2]*, (1)Department of Environmental Engineering, Changwon National University, "Korea, Republic of", (2)School of Smart and Green Engineering, Changwon National University, "Korea, Republic of"*

Polyamide 6, a widely used polymer, can release oligomers that leach into water or migrate into food. Toxicity predictions from ProTox 3.0 suggest potential risks associated with these oligomers, for instance 1,8-diazacyclotetradecane-2,9-dione (aminohexanoate cyclic dimer, AHCD), which has an estimated LD50 of 560 mg/kg and high probabilities of Blood Brain Barrier disruption (94%) and neurotoxicity (64%). Previous non-targeted analyses of drinking water tentatively identified Polyamide 6 oligomers (cyclic dimer to heptamer), motivating further investigation into their prevalence. This study optimized the target and suspect screening using liquid chromatography-high resolution mass spectrometry (LC-HRMS) to analyse six Polyamide 6 oligomers in 81 water samples, including purified drinking water (n = 59), tap water (n = 14), and sewage (n = 8). Calibration for AHCD was performed using the reference standard and internal standard (range: 0.1 200 ng/L; $R^2 = 0.9997$; LOD = 0.5 ng/L; LOQ = 1 ng/L), and recovery experiments in five replicates achieved recoveries of 89.1 126% with a relative standard deviation (RSD) of 13.0%. Predictive quantification for other Polyamide 6 oligomers using the Quantem tool was validated by spiking AHCD, showing comparable accuracy (recoveries: 86.5 123%; RSD: 13.1%). Results indicated the presence of six oligomers in purified water, with AHCD detected in 49.2% of samples (mean concentration: 86.3 ng/L; max: 828 ng/L) and total oligomer concentrations averaging 585 ng/L (max: 9,530 ng/L). The occurrence of Polyamide 6 oligomers in purified water was suggested to be associated with the use of polymer fiber wipes for the maintenance of water purifier tank. In tap water and sewage, only cyclic dimer, trimer, and tetramer were found. Tap water showed low total oligomer concentrations (max: 4.9 ng/L), whereas sewage exhibited significantly higher levels, particularly in influent from domestic sources (total concentration: 4,570 ng/L) and two fiber manufacturing facilities (total concentrations: 31,200 and 54,200 ng/L). Total oligomer concentrations declined through the sewage treatment, reaching 54 ng/L in the effluent sample. This study optimized and validated a (semi-)quantitative method for analysing Polyamide 6 oligomers in multiple water samples, providing new data to support environmental and health risk assessments for polymer derivatives.

4.02.P-We334 Elucidating the Role of Enzymes in Polymer Biodegradation: A Case Study on Poly(Aspartic Acid)

Doris Ribitsch[1]*, Karin Binder*[2]*, Miriam Kronfuss*[2]*, Jervis V. Thevathasan*[3]*, Soumya Daturpalli*[3]*, Glauco Battagliarin*[4]*, Andreas Kuenkel*[3] *and Georg M. Guebitz*[5]*, (1)ACIB - Austrian Centre of Industrial Biotechnology, Austria and Department of Agrobiotechnology, IFA-Tulln, Institute of Environmental Biotechnology, University of Natural Resources and Life Sciences Vienna, Austria, (2)ACIB - Austrian Centre of Industrial Biotechnology, Austria, (3)BASF SE, Germany, (4)Research Biopolymers, BASF SE, Germany, (5)Department of Agrobiotechnology, IFA-Tulln, Institute of Environmental Biotechnology, University of Natural Resources and Life Sciences Vienna, Austria*

Synthetic water-soluble polymers (WSPs) are organic molecules that dissolve, disperse, or swell in water to alter the physical properties of aqueous systems and formulations through gelation, thickening, emulsification, and stabilization. Due to their exceptional properties, they are widely used in our daily life such as in home and personal care products, cosmetics, and agrochemicals. After use, WSPs can enter into the environment, such as through wastewater treatment plants (WWTPs) or agricultural soils. However, only little information is available on their biodegradability in the environment.

Biodegradation is a multi-step process mediated via microbial metabolism. Due to their high molecular weight, WSPs must first be cleaved into smaller fragments for take up by microorganisms. This can occur abiotically or be performed by enzymes produced and secreted by microorganisms in the environment. Existing OECD biodegradation testing guidelines have been primarily developed for the testing of small

organic molecules. Nevertheless, standardized tests such as OECD 301 and 302 are currently used to assess biodegradability of polymers. However, the degradation mechanism of polymers, which necessitates break down into smaller fragments before microbial uptake and biodegradation, differs significantly from that of small molecules. As a result, existing methodologies and pass criteria may not be appropriate for assessing polymer biodegradation.
The commercially most successful synthetic poly(amino acid) is the water-soluble and anionic poly(aspartic acid). However, little is known about the biodegradability of tPAA. In this study, we investigated the interaction between the hydrolases from *Sphingomonas* sp. KT-1 and *Pedobacter* sp. KP-2, named Ss_hydrolase-1, Ss_hydrolase-2 and Ps_hydrolase-1, with tPAA and effects these enzymes have on tPAA biodegradation. Detailed investigations were performed to understand activities and elucidate synergistic action by using recombinant enzymes on tPAA. Finally, the individual and synergistic effect of the hydrolases have been investigated within an OECD 301F biodegradation test to showcase the potential of incorporating enzymes within existing standardized test to shorten testing times and better elucidate polymer biodegradation processes. These investigations aim to better understand the role of polymer molecular weight on microbial degradation and how this process is influenced by competent (extracellular) enzymes.

4.02.P-We335 Innovating on polymer degradation: Making two ends meet

Nathalie Vallotton[1], *Ben Reiner*[2], *Ligeng Yin*[3], *Vurtice C Albright III*[4] *and Lyndsay Leal*[3], *(1)Dow Chemical Company, Switzerland, (2)Core R&D, Dow Chemical Company, Collegeville, PA., United States, (3)Home and Personal Care R&D, Dow Chemical Company, United States, (4)The Dow Chemical Company, Midland MI, United States*

Polymers play a pivotal role in modern society by providing a multitude of technical functionalities in materials and products. They represent a vast and diverse aspect of the chemical space, often characterized by medium to very high molecular sizes and various functionalities. For polymers emitted down the drain, ultimate degradability becomes a favourable property. Yet, assessing the environmental fate of polymers poses scientific challenges, primarily due to their high molecular weight, which leads to low bioavailability impacting for example uptake in biodegradation studies.
In line with their emission routes, polymers used in Home and Personal Care products are evaluated for their biodegradation potential. However, the domain of applicability of standardized test guidelines, such as those from the OECD, does not include polymers. Therefore, the innovation of new materials faces two main challenges. The first is the need to accelerate the development of screening methods to inform product development, while the second is aligned to the need for the adaptation of standardized test methods to widen the applicability domain to polymers. In this presentation, we delve into methodologies for evaluating the biodegradation of polymers in aqueous systems during product development by use of screening and modified test methods.
At early stages of development, combining enzymatic assays with analytical techniques like 1H NMR spectroscopy enables the characterization of changes in structural features. Additionally, candidate polymers are evaluated using standard or modified OECD biodegradation screenings studies. Adaptions including the extension of the test durations, are valuable approaches in comparing the biodegradation polymers with similar structural properties.

4.02.P-We336 Are Bio-Based Monomers Environmentally Safer Alternatives to Bisphenol A Diglycidyl Ether?

Isabel Lopes[1], *Catia Venancio*[1], *Sara Costa*[1], *Márcio Barreto*[1], *Miguel Oliveira*[1], *Samuel Malburet*[2] *and Camille Chatard*[2], *(1)Centre for Environmental and Marine Studies (CESAM) & Department of Biology, University of Aveiro, Portugal, (2)Specific Polymers, France*

In the last decades, bio-based epoxy resins have been gained relevance as more environmentally friendly alternatives to traditional petroleum-based epoxy resins, as the latter have proved to constitute serious hazards to the environment. A key challenge on the shift from petroleum-based to bio-based polymers is the replacement of one of the most widely used building monomers for epoxy resins, i.e., the diglycidyl ether of Bisphenol A (DGEBA), without affecting the final functionality of the resin. Among the bio-based alternatives to DGEBA, that have been developed and used, is the bisphenol-free diglycidyl ether of vanillyl alcohol (DGEVA SP s catalogue reference SP-9S-5-005 CAS 1584677-14-4) that could be obtained from lignin. In this context, the present work aimed at a comparative characterization of the toxicity of DGEBA and the bio-based monomer DGEVA to freshwater biota. Additionally, the toxicity of cystamine (SP s catalogue reference SP-2-4-001 - CAS 51-85-4), a bio-based hardener (derived from amino acids) also incorporated in epoxy resins, was also assessed. To achieve the established objectives, the ecotoxicity of DGEBA and the two bio-based monomers was characterized by performing the following assays: 72-h growth rate inhibition with *Raphidocelis subcapitata*, 7-d growth rate inhibition with *Lemna minor*, 24-h acute toxicity assay with *Brachionus calyciflous*, 48-h acute toxicity assay with *Daphnia magna*, and 96-h embryo acute toxicity assay with *Danio rerio*. Overall, DGEVA revealed a lower toxicity, comparatively to DGEBA, for the tested species, with EC50s always above 73 mg/L. Regarding cystamine, no mortality or malformations were observed in D. rerio. For the other tested species, the estimated EC50s of cystamine ranged from 6.18 to 63.84 mg/L. In conclusion, the obtained results confirm that DGEVA is a more environmentally safer alternative to DGEBA, thus, supporting the premise that it is a more sustainable bio-based building monomer of epoxy resins.

4.03.P Statistics for Risk Assessment from Tried and Tested to New and Exciting Methods

4.03.P-Tu316 Applying Generalized Linear Mixed Models (GLMM) for the Evaluation of Ecotoxicological Endpoints in a Regulatory Context: A Framework Demonstrated by a Small Mammal Case Study

Peter Vermeiren[1], Torben Wittwer[2], Stephanie Coffinet[3], Felix von Blanckenhagen[1], Martin Vallon[4] and ***Oliver Jakoby**[2]*, *(1)Rifcon GmbH, Germany, (2)RIFCON GmbH, Germany, (3)UPL Corporation Ltd., Belgium, (4)RIFCON GmbH, Hirschberg, Germany*

Analysing data from ecotoxicological studies on small mammals to detect and evaluate effects of pesticide applications can be daunting due to the inherent variability of natural systems, the complex interactions between environmental factors, complexities such as non-linear dynamics, and the difficulties working with free ranging wild animals. Regression-based statistical approaches, including generalized linear and additive mixed effect models (GLMM, GAMM), have a long tradition in ecology to disentangle the influence of multiple factors on observed data. Such techniques have also gained attention in analysing data from higher tier enclosure and field studies conducted for environmental pesticide risk assessment. Nevertheless, GLMM analysis are often perceived as complex, leading to hesitation to account for their results in regulatory evaluations.

To enhance the uptake and understanding of GLMM and GAMM by regulators and ecotoxicologists, we aimed to present a structured framework of decision-steps to demystify the preparation, construction, validation, and evaluation of GLMM and GAMMs within the context of ecotoxicological field study data. This framework follows a two-stage approach where significance of treatment-related effects can be checked in both stages. A thorough data exploration, and model interpretation and visualization, complete the framework in a total of 7 steps.

The framework is demonstrated in a case study on voles exposed to a fungicide under field conditions. After exploratory data analysis, model alternatives were developed that are tailored to the different data types (counts, proportions, continuous data) recorded as endpoints of (semi-)field studies, and considering the repeated sampling within the same fields or enclosures and the potential non-linear dynamics of the endpoints over time. Different model alternatives were then compared through model selection, and the statistical power of the model evaluated through post-hoc Minimal Detectable Difference (MDD) testing. A final visualization for each endpoint assisted the interpretation of the statistical results.

The case study demonstrated the usefulness of the framework, to maximize the advantages of GLMM/GAMM analyses, namely, their adaptability to different data types, ability to incorporate all data within a single analysis (while excluding pseudoreplication), and ability to account for multiple influencing factors of direct and indirect interest to the study interpretation.

Disclaimer/Disclosure: The authors are gratefull to Arysta LifeScience Benelux SPRL for providing access to the anonymised dataset, and to colleagues at RIFCON GmbH for their work in collecting the original dataset.

4.03.P-Tu317 Four-Parameter Nonlinear Regression and Maximum Achievable Effect in Ecotoxicology: Just Visually Appealing or Biologically Relevant?

***Benjamin Daniels**[1]*, *Udo Hommen[2] and Monika Ratte[1], (1)ToxRat Solutions, Germany, (2)Fraunhofer Institute for Molecular Biology and Applied Ecology (IME), Germany*

In ecotoxicology, "ECx" refers to the "concentration that causes x% effect" (OECD 2006). This seems to be a precise definition, but is typically only clear for ECx values calculated for inhibitions of metric

variables from two- and three-parameter regressions, as they assume that the minimum of the affected variable is zero. In contrast, a four-parameter regression (4pr) assumes that the maximum achievable effect levels off at a value of the variable greater than zero. From this, several critical issues arise for ECx calculation: As the maximum effect does not necessarily mean 100% inhibition related to control, two types of ECx can be calculated. A relative EC50 is the concentration which shows the half maximal inhibition, whereas an absolute EC50 is the concentration which shows 50% inhibition related to control. The latter is what people intuitively associate with the meaning of ECx, whereas a relative ECx from a 4pr cannot be compared to ECx from other regressions. However, depending on the magnitude of the fitted maximum achievable effect, an absolute ECx from 4pr can be considerably higher than the corresponding relative ECx. Moreover, absolute ECx are limited to the maximum achievable effect, i.e., it may not be possible to determine an absolute EC50 at all.
In addition, a maximum achievable effect, and thus a justification for 4pr, may be claimed from a statistical point of view, even though it does not actually exist for the corresponding variable from a biological point of view. Why, for example, should a growth rate of a macrophyte not fall to zero if the exposure is further increased? Therefore, the choice of model should be based on the assumed underlying mode of action for a certain variable rather than on producing a visually appealing fit. This may be at the expense of the width of the confidence intervals of the ECx.
In summary, 4pr should only be used if there is a plausible biological mechanism to explain a maximum inhibition < 100%. In these cases, the absolute ECx values appear to more closely correspond with what is sought for regulatory purposes. In any case, if 4pr is applied, the calculation method used (relative or absolute toxicity estimates) must be clearly stated to avoid erroneous conclusions and to ensure transparency. Overall, the use of 4pr to determine ECx values for biological variables needs to be clarified in future guidance documents.

4.03.P-Tu318 Leveraging Bayesian Regression Models and Data Literacy for Better Decision-Making

Raoul Wolf[1]*, David Fox*[2] *and Jannicke Moe*[3]*, (1)Norwegian Geotechnical Institute (NGI), Norway, (2)Environmetrics Australia, Australia, (3)Norwegian Institute for Water Research (NIVA), Norway*
Environmental risk assessments (ERAs) rely heavily on the specific domain context and the availability of suitable data. Collecting high-quality data for ERAs can be challenging due to the variability in reliability across experimental sources and in silico information. The statistical analysis of information for ERAs is a current topic of debate, with an ongoing effort to revise OECD document 54 to improve the routine data analysis of ecotoxicological data.

For robust ERAs, understanding the data origin and its generation processes is vital. Challenges such as variations in experimental conditions, incomplete datasets, or measurement limits necessitate careful evaluation, especially in the context of ecotoxicology. These factors inform the selection of appropriate modelling strategies and, in the case of Bayesian data analysis, the implementation of meaningful priors.

Bayesian regression models (BRMs) provide flexible tools to address these challenges, allowing for the inclusion of diverse data types and the quantification of uncertainties. Beyond the Gaussian default, BRMs can incorporate alternative probability distributions tailored for count, survival, or concentration data. Features such as data weights (e.g., reliability), censoring (e.g., values below detection limits), and truncation (e.g., bounded response variables) can be modelled directly, reducing the need for a priori data manipulation. Advanced extensions, such as non-linear modelling (e.g., smoothing splines) and hierarchical components (e.g., random effects), further enhance BRM applications across all genres of ecotoxicology. The Bayesian approach allows for a direct probability quantification of a hypothesis, rather than the probability of the data alone.

Interpreting BRM results effectively is critical for assessing model quality and drawing meaningful conclusions for ERAs, such as through post hoc analyses and credible significance testing (e.g., ECX, BMD, or NSE). Technical aspects also include understanding, visualizing, and communicating posterior results and their uncertainties.

Collectively, these aspects can be viewed as data literacy for BRMs a critical skill for enhancing the quality of ERAs within regulatory frameworks. A stronger emphasis on data literacy, coupled with a broader adoption of BRMs through initiatives like the revision of OECD document 54, holds significant potential for improving ERA practices and fostering better understanding among stakeholders.

4.03.P-Tu319 Alternative Approaches to Deal with Difficult Cases in the Statistical Analysis of Ecotoxicological Data

***Zhenglei Gao**[1], Ludwig A. Hothorn[2] and John W. Green[3], (1)Data Science, Bayer AG, Germany, (2)Retired from Leibniz University Hannover, Germany, (3)John W Green Ecostatistical Consulting LLC, United States*

Endpoints such as Lowest Observed Effect Concentrations (LOECs) and Effect Concentrations (ECxs) derived from statistical analyses of ecotoxicological studies serve as one of the pillars for regulatory risk assessment. Sound experimental design and appropriate, fit-for-purpose analysis procedures are essential for well-informed regulatory decision-making. Decision flowcharts are valuable tools for guiding the analysis of ecotoxicological data and examples of decision flowchart can be found in OECD 54 and many OECD test guidelines. These flowcharts often require pretests to assess test assumptions such as normality and homogeneity of variance and to decide which test to use for certain type of data characteristics. Based on these pretests outcomes an appropriate test out of a pre-selected list should be selected. While decision flowcharts can efficiently guide routine analysis, they can occasionally yield misleading results. It is well-known that preliminary assessment in these flowcharts do affect the power characteristics of subsequent tests and can avoid the use of a low power test. However, it is not yet emphasized that the purpose of the flowchart is not to find the most powerful test for a dataset with a specific characteristic, but to find an appropriate method that is suitable for an endpoint with perceived general characteristics. In this presentation, real and synthetic data examples are presented to illustrate inconsistent power performance of different tests within the flowcharts, explaining when and why the decision chart does not work as expected for a given dataset and what can be done when the decision flowcharts fail. Our work highlights the importance of understanding the trade-offs between good experimental design, statistical power and robust analysis techniques in ecotoxicology. By emphasizing the need for appropriate test selection, the importance of proper usage and the potential pitfalls of decision flowcharts, we aim to contribute to improved experimental design and more reliable data generation and analysis for regulatory purposes. We propose using alternative robust approaches when deviation from the decision charts is necessary. Furthermore, we stress the necessity of conducting sanity checks, including visual inspections of model fit and data, following the analysis to ensure the validity of results. This holistic approach ultimately supports more informed regulatory decision-making in the field of ecotoxicology.

4.03.P-Tu320 Land-Use Suitability Decision Support System Tools: GIS & Geostatistical Models Versus CLEA & ICRCL Approaches for Tangier Portsmouth Landfill Site Investigation

***Precious Onyinyechi Odika**, School of Environment, Geography and Geosciences, University of Portsmouth, Portsmouth, United Kingdom*

Contamination in soils can create risks of harm to human health and the environment. This study reassessed the spatial distribution patterns of some selected heavy metals (Pb, As, Hg, and PAHs) on soils in the Tangier Road area of Portsmouth, UK using geostatistics approaches including GIS models against some previously used CLEA and ICRCL approaches. The study analysed a total of 152 soil sample data-set obtained from the Department of Environmental Geology and Contamination (EGC), School of Earth and Environmental Science (SEES), University of Portsmouth, England, UK to determine whether contaminants are significant and their extent, nature, degree, and possibility of posing risk. This study, using data-set from the Parkman and Clayton report, reviews CLEA and ICRCL approaches. ICRCL threshold (now withdrawn) showed 500, 1, 10 and 50 mg/kg for Pb, Hg, As and PAH for allotment and corresponding values of 2000, 20, 40 and 1000 mg/kg for open spaces, parks and playing fields. The site was deemed to present risk based on the ICRCL report. For allotment, the Soil Guideline Values (SGV) of Pb, Hg and As are 452, 26 and 43 mg/kg respectively, and the generic assessment criteria (GAC) for PAHs is 2.1. For residential, SGV for Pb, Hg and As are 450, 1.0 and 32 respectively. Using more environmentally friendly and scientific approaches, geostatistics and GIS models show non-normal distribution patterns of contaminants. While semi-variograms of Pb, Hg, As and PAHs indicate a blanket structure for As, and plume structures for Pb, Hg, and PAHs, GIS and Surfer kriging delineate varying degrees of hotspots. A threshold exceedance analysis of As provides evidence of low risk. The conceptual site model (CSM) suggests possible incomplete pollutant linkages. A comparative analysis of CLEA and geostatistics/GIS provides evidence that results from CLEA/ICRCL models alone are insufficient to categorise the site as posing significant possibility of significant harm (SPOSH) across the entire landfill site. It is necessary to ascertain the source and origin of these contaminants and their bioaccessibility and bioavailability to determine the land's usability for future development.

4.03.P-Tu321 Workshop on Generating BMD10s for Wild Mammals Under EFSA's 2023 Bird and Mammals GD

***Manousos Foudoulakis**[1], Amy C. Brooks[2], Helena Crosland[2], Nadine S. Taylor[2], Markus Ebeling[3],*

Thomas Bean[4], Steven Kragten[5] and Joachim Nopper[6], (1)Corteva Agriscience, Greece, (2)Cambridge Environmental Assessments (RSK ADAS), United Kingdom, (3)Bayer AG, Crop Science Division, Germany, (4)BASF Corporation, Agricultural Solutions, Research Triangle Park, NC, United States, (5)Syngenta Agro GmbH, Frankfurt, Germany, (6)BASF SE, Agricultural Solutions - Ecotoxicology, Germany
The EFSA GD 2023 on bird and mammal risk assessment for plant protection products has introduced new and challenging settings which require more technical guidance. Of these, the generation and use of BMD10 endpoints, instead of NOAELs, is probably the most notable.
The selection of endpoints from toxicology studies for BMD10 calculation, and the actual calculation, is not always straightforward. This is particularly evident for the area of wild mammals, where the BMD10s are based on the data set generated for the toxicological risk assessment, with typically 3 dose levels tested and reporting numerous measurements which may not always be relevant for wild mammals.
To address these challenges, a workshop has been organized with the objective to facilitate participation of the main stakeholders involved in the area of regulatory wild mammal risk assessment for pesticides in Europe under the EFSA GD 2023 (regulatory authorities, companies and CROs).
This workshop covers procedural and technical challenges, including data selection and processing, with the aim of contributing to the development of procedures that will aid in transitioning from chronic NOAELs to BMD10s when the EFSA GD 2023 will be implemented in the European Union later in 2025.
This poster outlines the main discussion points, challenges identified, agreements achieved and proposed paths forward.

4.03.P-Tu322 Avian Reproduction Studies: Alternative Experimental Design and Statistical Methodology
*John W. Green[1], **Manousos Foudoulakis**[2], Zhenglei Gao[3], Steph Plautz[4], Yushan Gu[4], Jonathan D. Maul[5], Alex Mauss[6], Thomas Bean[7], Seamus Taylor[8], Mark Christ[9] and Katharina Ott[10], (1)John W Green Ecostatistical Consulting LLC, United States, (2)RAS, Corteva Agriscience, Peristeri, Greece, (3)Data Science, Bayer AG, Germany, (4)Corteva Agriscience, United States, (5)Syngenta Crop Protection LLC, United States, (6)Bayer AG, Germany, (7)BASF Corporation, Agricultural Solutions, Research Triangle Park, NC, United States, (8)ADAMA Deutschland GmbH, Germany, (9)Bayer CropScience LP, United States, (10)BASF SE, Agricultural Solutions - Ecotoxicology, Germany*
Recent EFSA (2023) guidance on risk assessment for birds and mammals proposes using regression or benchmark dose (BMD) modelling to estimate 10% effect concentrations in avian reproduction studies (OECD TG 206, OCSPP 850.2300). Previously, studies aimed to determine a no effect concentration (NOEC) using primary 3 test concentrations plus a control, each with at least 16 male-female pairs. This study design, however, often lacks the sensitivity needed for accurate dose-response and BMDx estimation.
A collaborative working group of industry representatives and independent scientists collected a substantial avian reproduction study database. These data formed the basis for an extensive computer simulation study benchmarking several alternative experimental designs. The objectives were to (1) propose alternative experimental designs that support both BMD10 estimation and NOEC determination in avian reproduction studies while limiting bird use, preserving statistical power for detecting treatment effects, and maintaining the ability to meet the validity criteria in internationally-accepted test guidelines, most notably ?29 eggs laid per hen in the control group; (2) refine statistical methods recommended by Green et al. (2022) to enhance effect estimation precision.
According to the simulations, two experimental designs would support both BMD10 and NOEC determination without increasing the number of birds used in the study, while still allowing all validity criteria to be met, provided that studies are allowed to continue until ?29 egg are laid per hen: 1) 8 weeks of egg laying with 16 pens per group in 5 treatment groups and a control and 2) 8 weeks of egg laying with 18 control pens and 16 pens in each of 4 treatment groups.
The analysis concludes that some responses from some studies cannot be fit reliably by most commonly used dose-response regression models and a NOEC must be used. EFSA guidance also acknowledges this possibility.
The poster summarizes recommendations concerning model selection for BMD estimation and model averaging, along with acceptance and goodness-of-fit criteria. It also proposes solutions for challenging cases.

4.03.P-Tu323 Critical Evaluation and Meta-Analysis of Ecotoxicological Data on Per- and Polyfluoroalkyl Substances (PFAS) in Freshwater Species

Lixi Wang[1], *Yang Tong*[2], *Xinglu Liu*[2], *Jinxia Liu*[2] *and Wenxin Liu*[1], *(1)Key Laboratory for Earth Surface Processes, College of Urban and Environmental Sciences, Peking University, China (Mainland), (2)Civil Engineering Department, McGill University, Canada*

Despite the increasing concern regarding the ecological risks posed by per- and polyfluoroalkyl substances (PFAS), a lack of comprehensive understanding of their actual ecotoxicity remains. Through a meticulous examination of 91 peer-reviewed studies investigating effects at a population level and constructing probabilistic species sensitivity distributions (PSSDs), we present a state-of-the-science hazard assessment of PFAS in freshwater species. Using data subsets containing suboptimal data led to an overestimation of the predicted no-effect concentrations (PNECs) of PFAS. We report PNECs of perfluoroalkyl carboxylic acids (PFCAs) and perfluoroalkyl sulfonates (PFSAs) in freshwater to be 4.8 2000 ?g/L and 0.4 8.9 ?g/L, respectively, derived from high-quality data. Statistical analyses revealed that both functional groups and carbon chain length significantly influenced ($p < 0.05$) the variations in toxicity observed among different PFAS. This study underscores the importance of obtaining high-quality PFAS ecotoxicity data to comprehend associated hazards. The PNECs of PFAS derived in this study are higher compared to those of micro/nanoplastics and persistent organic pollutants. Our research offers valuable insights into prioritizing the regulation of more toxic PFAS.

4.03.P-Tu324 How Normalization and Choice of Endpoint of Receptor Based In Vitro Assays Affect the Results

Nina Cedergreen[1], *Emilie Jakobsen*[2], *Mikkel A.H. Rafner*[2] *and Johan Lundqvist*[3], *(1)Plant and Environmental Sciences, University of Copenhagen, Denmark, (2)University of Copenhagen, Denmark, (3)Biomedicine and Veterinary Public Health, Swedish University of Agricultural Sciences (SLU), Sweden*

Receptor based in vitro tests indirectly assesses to what degree a specific receptor interacts with a chemical. The strength by which it does so, however, depend on a range of factors such as e.g. cell viability and biochemical functionality, transfection stability, chemical potency, reader sensitivity etc. Both baseline and positive controls are therefore included in the assays. The purpose of the baseline controls is to establish a baseline signal reading of cells not affected by chemicals, while the purpose of the positive control(s) is to set a maximum response indicating the maximal signal the cells are able to perform when all receptors in the cells are occupied by a ligand with high affinity to the receptor, all the time (i.e. receptor saturation).

The aim of this study was to investigate the factors leading to variable baseline and positive controls, and evaluate the consequences of the methods used to normalize readings to baseline and positive controls for the final results of the assay. In addition, we wanted to assess the consequences of the models and endpoints used (linear versus symmetric and asymmetric sigmoid models, benchmark doses, low EC-values and 50% effect concentrations relative to positive controls).

We used data from three widely used receptor assays: the AREc32 cell line for Nrf2 activity, the DR-EcoScreen cell line for AhR activity and the VM7Luc4E2 cell line for ER activity tested on >300 wastewater effluent samples. The results showed that the normalization procedure had a large effect on the final results. First, we discovered that even ultra-pure evaporated solvents could have an effect in the AhR assay, visualising solvents as a confounding factor when working with up-concentrated environmental samples contained in a solvent. Subtracting or dividing by the baseline control, which are both recommended procedures depending on the assay and the protocol used, shifted the resultant EC-values fitted to normalized data. Variations in positive controls are also discussed in relation to the >100% induction rations often observed. We conclude that raw data should always be given and normalization procedures should be explicitly described when reporting in vitro results, facilitating re-analysis of data.

4.03.P-Tu325 AI-aided Chronic Mixture Risk Assessment Along a Small European River in Central Germany

Fabian G. Weichert[1], *Pedro Inostroza*[2], *Jorg Ahlheim*[3], *Thomas Backhaus*[4], *Werner Brack*[5], *Mario Brauns*[3], *Patrick Fink*[6], *Martin Krauss*[5], *Patrik Svedberg*[7] *and Henner Hollert*[8], *(1)Goethe University Frankfurt, Germany, (2)Biological and Environmental Sciences, RWTH Aachen University, Aachen, Germany, (3)Helmholtz Center for Environmental Research (UFZ), Germany, (4)RWTH Aachen University, Aachen, Germany, (5)Department of Effect Directed Analysis, Helmholtz Center for Environmental Research (UFZ), Leipzig, Germany, (6)Department of Aquatic Ecosystem Analysis and Management, Helmholtz Center for Environmental Research (UFZ), Leipzig, Germany, (7)Department of Biological & Environmental Sciences, University of Gothenburg, Göteborg, Sweden, (8)Evolutionary Ecology and Environmental tToxicology, Goethe University Frankfurt, Germany*

The vast amount of registered chemicals leads to a high diversity of substances occurring in the environment and the creation of new substances outpaces chemical risk assessment as well as monitoring strategies. Hence, risk assessment strategies need to be modified to remain aligned with the rapid development and marketing of new substances. Here we performed a longitudinal chronic mixture risk assessment considering a real-world case study scenario with diverse anthropogenic impact types characterised by different land uses along a river in Central Germany. We selected six sampling sites with distinct land use types along the Holtemme River in Central Germany based on knowledge from prior studies. At each sampling site, we sampled river water using large-volume solid phase extraction. Following target chemical analysis using liquid chromatography coupled with high-resolution mass spectrometry, we were able to quantify 192 out of 457 substances above the respective limit of detection. For about 34% of them, we obtained empirical chronic effect data for freshwater organisms from the US EPA ECOTOXicology Knowledgebase. Furthermore, we applied the open-source artificial intelligence (AI) model TRIDENT to predict chronic toxicity for all substances. TRIDENT combines the use of a BERT-based transformer and a deep neural network to characterise the toxicity of molecular moieties from the SMILES code. A multi-scenario mixture risk assessment was conducted for three taxonomic groups, using the concentration-addition concept and considering various hazard and exposure scenarios. The results showed that the chronic risk estimates for all taxonomic groups were considerably higher when the empirical data was amended with data from in silico modelling. We identified hot spots of chemical pollution and our analysis indicated that fish were the most vulnerable taxonomic group, with pharmaceuticals being the most relevant risk drivers. Our study exemplifies the application of an AI model to predict chronic risk for aquatic organisms in combination with the consideration of multiple risk scenarios, that may complement future risk assessment strategies.

4.03.P-Tu326 Revisiting Some Decision Flowcharts for the Statistical Analysis of Ecotoxicological Data

Zhenglei Gao[1]*, Ludwig A. Hothorn*[2] *and John W. Green*[3]*, (1)Data Science, Bayer AG, Germany, (2)Retired from Leibniz University Hannover, Germany, (3)John W Green Ecostatistical Consulting LLC, United States*

Decision flowcharts is an important tool in the analysis of ecotoxicological data and examples of decision flowcharts can be found in OECD 54 and many OECD test guidelines. In those decision flowcharts, often pretests need to be conducted for various test assumptions such as normality and homogeneity of variance to decide which test to use for certain type of data characteristics. For example, trend tests are prescribed when monotonicity test pass; nonparametric tests are used when inhomogeneous variances or non-normality are identified. Based on these pretests outcomes an appropriate test out of a pre-selected method list such as Williams or Dunnett, Bonferroni-Welch-t tests, stepdown Jonckheere-Terpstra test, Bonferroni U-test, Dunn's test should be selected.

While decision flowcharts are generally useful for guiding analysis, some of them contain redundant steps and they can occasionally yield misleading results. In this work, real and synthetic data examples are given to illustrate how and why a certain decision flowchart guided analysis can lead to results against intuition, what can be done when the decision flowcharts don t work properly due to pre-tests that lead to a test that is not appropriate for the concurrent data. For instance, a trend test goes wrong where a robust test can rescue. We advocate for the use of robust approaches instead of pre-tests in decision flowcharts. For example, Delacre et al. (2017) have proposed that psychologists should by default use Welch’s t-test instead of Student's t-test or the two-step procedure (first performing Levene's test, then deciding which test to use), despite the latter's marginally better power when equal variance assumption is true. Similarly, we suggest adopting the more robust Dunnett test with unequal variance assumptions by default rather than the current practice of using standard Dunnet test which requires equal variance for valid results. We question whether it is worthwhile to choose different tests in case one is a few percent more powerful in specific data conditions through simulation study. Additionally, we discuss other robust approaches, such as using sandwich variance estimators for multiple contrast test of Dunnett and Williams (Jaki, 2013) that is robust against variance heterogeneity in balanced and unbalanced designs. Finally, we propose that a sanity check including visual inspection of the model fit and the data should be always conducted after the analysis.

4.03.P-Tu327 Equivalence Testing in Honeybee Semi-Field Studies

Magdalena M. Mair[1]*, Zhenglei Gao*[2]*, Mark Miles*[3]*, Vanessa Roeben*[3]*, Florian Hartig*[4] *and Tobias*

Pamminger[5], (1)Statistical Ecotoxicology, University of Bayreuth, Germany, Germany, (2)Data Science, Bayer AG, Germany, (3)Bayer AG, Germany, (4)Theoretical Ecology, University of Regensburg, Germany, (5)Early Environmental Safety, Bayer AG, Germany
In 2023, the European Food Safety Authority (EFSA) released the Revised guidance on the risk assessment of plant protection products on bees (*Apis mellifera*, *Bombus* spp. and solitary bees) . This revision introduced numerous significant modifications to the environmental risk assessment (ERA) of pollinators, including fundamental changes to the statistical evaluation of honeybee (*A. mellifera*) semi-field and field tests shifting from standard null hypothesis significance tests to equivalence testing. Unlike conventional null hypothesis significance tests which are designed for demonstrating the presence of effects, equivalence tests aim at demonstrating that effects fall below a pre-specified threshold. While this approach is successfully used in the field of pharmacology, its applicability to honeybee (semi-)field data within the context of ERA remains uncertain, especially considering the higher intrinsic variability associated with these test systems and the specific protection goal set at 10%. In the present study, we use negative control data of Bayer AG semi-field honeybee tests to quantify the test system s inherent variability for the main endpoint of colony strength (i.e. number of bees) at the end of the exposure period. Based on the assessed variability, we conduct data simulations to explore which true effect sizes can be reliably (i.e. with high enough (80%) power) detected as being below the 10% threshold within the equivalence testing framework. We discuss the implications of these results for the design of honeybee semi-field studies and for the proposed pollinator ERA.

4.04 Mechanistic Effect Models and Statistical Methods in Regulatory Science: Progress and Innovation for Environmental Risk Assessment?

4.04.T-01 Towards the Implementation of FAIR Principles for Mechanistic Effect Models (MEMs) in the Regulatory Environmental Risk Assessment (ERA) of Pesticides

***Alberto Linguadoca**[1], Edoardo Carnesecchi[2], Sandrine Charle[3], Andreas Focks[4], Davide Ghibin[2], Jonathan Haselman[5], Alessio Ippolito[1], Kehinde Olajide[1] and Ivana Teodorovic[6], (1)European Food Safety Authority, Environment, Plants and Ecotoxicology (PLANTS) unit, Italy, (2)European Food Safety Authority, Integrated Data (IDATA) unit, Italy, (3)NRS, UMR 5558, Laboratory of Biometry and Evolutionary Biology, France, (4)Research Center Environmental Systems Research, Osnabruck University, Germany, (5)U.S. EPA, Office of Research and Development, Great Lakes Toxicology and Ecology Division, United States, (6)Department of Biology and Ecology, Laboratory for Ecophysiology and Ecotoxicology LECOTOX, University of Novi Sad, Serbia*
There is growing consensus that overreliance on experimental ecotoxicology and reductionist approaches in regulatory ERA may restrain risk assessment conclusions to a limited range of tested scenarios. Future risk assessment frameworks may require more explicit representations of ecological system complexity to better reflect case-specificity in risk assessment conclusions. In this context, modelling may become pivotal for designing new holistic risk assessments which might represent a paradigm-shift in prospective and retrospective ERA.
However, despite efforts aimed to define a role of MEMs in the regulatory ERA of pesticides, we remain some distance away from their routine implementation in prospective and retrospective ERA approaches. One noteworthy initiative undertaken by EFSA aimed to improve model acceptance in ERA has been the establishment of a Working Group (WG) on effect models in ERA , which aims to consolidate frameworks for the assessment of models in the prospective regulatory risk assessment of pesticides. In this presentation, we aim to present the views of the EFSA WG on how the careful stewardship of data, software, model documentation and model assessment documentation may contribute to overcoming some of the impediments behind the regulatory acceptance of MEMs in regulatory ERA.
Building on the original conceptualisation by Wilkinson et al. (2016), here we aim to present a regulatory perspective on the implementation of Findability, Accessibility, Interoperability and Reusability (FAIR) principles to MEMs in regulatory ERA.
Our work on the FAIR principles fits into and works in concert with other activities taliored to producing standards for the design, use and assessment of MEMs in ERA. These include establishing Good Modelling Practices, best practices for model documentation and model use or assessment.
In my presentation I will summarise the work undertaken by the EFSA WG on effect models on the conceptualisation of FAIR principles for effect models in the regulatory ERA of pesticides wich will result in a publication by the first quarter of 2025. I will provide background on the community and regulatory

needs which motivated this activity. I will present the conceptualisation and implementation advice of the FAIR principles by the WG applied to MEMs in ERA, focussing on actions which may require prioritisation and long-term goals. Finally I will discuss challenges and blockers for their implementation.

4.04.T-02 BufferGUTS – A Toxicokinetic-Toxicodynamic (TKTD) Model for Above-Ground Terrestrial Invertebrates

Leonhard Urs Bürger *and Andreas Focks, Institute of Mathematics, Osnabrück University, Germany*

Mechanistic models can help to reduce animal testing by getting more information out of already existing datasets and can help to improve our understanding of effect processes. Toxicokinetic-toxicodynamic (TKTD) models link exposures and effects using mechanistic assumptions. The General Unified Threshold Model of Survival (GUTS) TKTD model is already deemed ready to use for aquatic species by the European Food Safety Authority (EFSA). To facilitate more event-based (feeding, contact, overspray) exposures in above-ground terrestrial systems, we developed a new generic TKTD model for above-ground invertebrates called BufferGUTS. It is based on GUTS but includes an intermediate buffer between the external exposure and inside of the organism. This buffer can be interpreted as residues on the exoskeleton or in the stomach, depending on the uptake route. Such an uptake behaviour is mechanistically reasonable and observable in laboratory experiments. Our model was tested against the reduced GUTS models and the honeybee specific BeeGUTS model (Baas et al., 2022) for 51 honeybee datasets (acute and chronic oral and acute contact) for 13 pesticides. BufferGUTS was able to perform (based on performance metrics) comparably or outperform the other models without using any species or substance-specific assumptions and the same number of parameters. The model performed as well for other non-bee arthropod datasets; thus we assume it can be used for all kinds of above-ground invertebrates. Having such a universal framework for above-ground invertebrates will enable the comparison and potentially even interpolation between species and substances, reducing the need for additional animal testing.

Disclaimer/Disclosure: This work was in part funded by the European Food Safety Authority (EFSA) as part of the AENEAS project (OC/EFSA/ED/2021/02).

4.04.T-03 Breaking Up is Hard to Do? Assessing Growth and Reproduction in *Lumbriculus variegatus* after Antidepressant Exposure by using a Novel DEB Model Approach

Jacqueline Hilgendorf[1]*, Neil Sherborne*[2]*, Diogo Filipe Nunes Cardoso*[1]*, Jesper G. Sorensen*[3] *and Susana Loureiro*[1]*, (1)Centre for Environmental and Marine Studies (CESAM) & Department of Biology, University of Aveiro, Portugal, (2)Syngenta Ltd., Jealott's Hill International Research Centre, United Kingdom, (3)Department of Biology, Aarhus University, Denmark*

Environmental risk assessment (ERA) of chemicals often relies on acute toxicity tests using high concentrations, focusing mainly on lethal effects. This substantially differs from the long-term, low-level exposures which can occur in the field and that may lead to sublethal effects over time. Dynamic Energy Budget (DEB) models provide a framework to bridge this gap by modelling energy allocation throughout an organism s lifecycle, allowing for more realistic exposure assessments. Although DEBtox models have recently gained attention, they are underutilized for sediment dwelling organisms like *Lumbriculus variegatus*, a species recommended for ERA. *L. variegatus* has an unusual reproduction by fragmentation, a dynamic currently not captured in conventional DEB models, which mainly describe sexual reproduction. This fragmentation can increase transfer of toxicants from mother to offspring. Here, we propose a mechanistic DEB approach to incorporate fragmentation, aiming to improve predictions of chemical impacts on model species with non-conventional reproduction types.

For the model calibration, we conducted a 28-day chronic experiment exposing *L. variegatus* to fluoxetine in sediment at three concentrations (0.0025, 0.25, and 25 mg/kg) and a control treatment. Growth, reproduction, and mortality were observed at seven distinct time points by distinguishing mature adults, mothers (recently split adult worms), and offspring. Our DEB model accounts for *L. variegatus* fragmentation by several extensions, including, among others, incorporating a juvenile starvation phase for head regeneration post-split. Results indicated two reproductive phases over the 28 days in the controls and a reproduction delay at higher exposure levels. By the end of the experiment, offspring numbers were significantly lower in the highest exposures, while growth of the offspring remained unaffected. This delay in reproduction highlights sublethal developmental effects often missed by conventional exposure assessment.

We conclude that monitoring the development of the organisms over time, rather than solely at the experiment's end, gives important information about the chemical's mode of action. Furthermore, a better understanding of the organism's life cycle and the time point of reproductive events could improve standardized guidelines and reduce variability in chronic test results.

Disclaimer/Disclosure: This Ph.D. position is part of the CHRONIC project "Chronic exposure scenarios driving environmental risks of Chemicals," which is an Innovative Training Network (ITN) funded by the European Union's Horizon 2020 research and innovation program under the Marie Sklodowska-Curie Actions (MSCA); CHRONIC Grant agreement ID: 956009. We acknowledge financial support to CESAM by FCT/MCTES (UIDP/50017/2020+UIDB/50017/2020+LA/P/0094/2020) through national funds.

4.04.T-04 Handling Experimental Variability in the Context of Calibration and Validation of DEB-TKTD Models: A Case Study using Cross-Laboratory Results for *Daphnia magna*

Marie Trijau[1], Carlo Romoli[2], Liubov Zakharova[1], Benoit Goussen[2], Erik B. Muller[2], ***Neil Sherborne**[3]* *and Roman Ashauer[4], (1)ibaconGmbH, Germany, (2)ibacon GmbH, Germany, (3)Syngenta Ltd., United Kingdom, (4)Syngenta Crop Protection AG, United Kingdom*

Traditional environmental risk assessment of plant protection products (PPP) is usually based on controlled laboratory experiments. However, intra- and inter-laboratory variability in the toxicity endpoints are often observed for a same species-compound combination. This variability originates from various factors, including the genetic variability among organisms and strains, the organism health, the food quality or the test conditions in the laboratory. In practice, the exact origin of the observed variability is difficult to identify and the factors hard to disentangle from one another. In the context of mechanistic effect modelling, toxicity test data are used to calibrate and validate toxicokinetic-toxicodynamic (TKTD) models, such as DEB-TKTD models, which focus on sublethal effects at the organism level. These models have been identified as a potentially powerful tool for use in risk refinement as part the environmental risk assessment of PPP. So far, the impact of variability in the toxicity test outcomes on the calibration and validation process of DEB-TKTD models has not been clearly assessed. This is essential in case substantial variability is present among several data sets used in the model calibration or between the data set(s) used for calibration and those used for validation. In our case study, a DEB-TKTD model was calibrated and validated on two sets of bespoke cross-laboratory experiments conducted with *Daphnia magna* exposed to time-variable concentrations of the fungicide azoxystrobin. This study contributes to the portfolio of case studies of DEB-TKTD implementation for aquatic ERA, demonstrates how the modelling can overcome challenges of variability in biological data and identify the best modelling strategy.

4.04.T-05 Integrated Risk Assessment for Pyrethroids: A "Proof of Concept" Approach for Toxicokinetics' Supported NAM-based Toxicodynamics

***Ana Fernandez Agudo**, Maria del Carmen Gonzalez Caballero and Jose V. Tarazona, National Environmental Health Center (CNSA-ISCIII), Spain*

Pyrethroids, widely used insecticides, pose potential risks to wild mammals due to their neurotoxicity and bioaccumulation in critical organs. Traditional risk assessment methods often fall short in capturing the full range of toxicological impacts. This study introduces an innovative approach that integrates toxicokinetics (TK) and mechanistic toxicodynamics (TD) to assess pyrethroid risks more comprehensively.

By combining in silico modeling and in vitro bioactivity data, this approach enables a detailed evaluation of aggregate and combined risks, focusing on internal dose-response relationships and organ-specific toxicity. A key innovation is the use of relative potencies to compare biological pathways and refine risk assessment methods, particularly for organs susceptible to long-term bioaccumulation.

This study provides a robust framework for ecological risk assessment, bridging the gap between experimental data and real-world exposure scenarios. The findings highlight the importance of considering intracellular concentrations in toxicological evaluations and demonstrate the value of combining TK and TD for a more accurate assessment of pyrethroid risks. This approach can be applied to other chemical classes, contributing to improved regulatory decisions and risk management strategies.

4.04.P Mechanistic Effect Models and Statistical Methods in Regulatory Science: Progress and Innovation for Environmental Risk Assessment?

4.04.P-Tu328 Using GUTS Models to Predict Margins-of-Safety to Effects of Measured Pesticide Mixtures

Paula Scharlach[1] *and Andreas Focks*[2]*, (1)Osnabrück University, Germany, (2)Institute of Mathematics, Osnabrück University, Germany*

The extensive use of pesticides has raised environmental concerns due to their potential to contaminate soil and water and impact non-target organisms. Knowing that organisms in the environment are affected by a wide range of exposure to different chemicals, especially the effects of mixtures and their predictions, is crucial for Environmental Risk Assessment (ERA). Toxicokinetic-toxicodynamic models, such as the General Unified Threshold Model of Survival (GUTS) framework, can be used to predict mixture effects over time based on damage addition (DA) and independent action (IA). This study aims to predict the mixture effects of pesticide concentration measurements in a German monitoring study (KgM) using the GUTS model framework. The crustacean *Gammarus pulex* serves as a reference non-target organism. For the calculations of mixture toxicity, we categorized substances based on their modes of action (MoA) to identify, a priori, the compounds for which damage addition is anticipated. The exposure profiles obtained from the KgM were subsequently simplified by aggregating the concentrations of substances within the corresponding MoA groups, applying a weighting factor derived from the ratio of LC50 values. We aim to quantify the potential effects of the measured pesticide mixtures at each monitoring site by calculating LP50 values as a measure of the margin of safety relative to risk. Initial results show a wide range of LP50 values considering the two substances dimethoate and propiconazole and their corresponding MoA groups for the different measurement sites, indicating different pesticide contamination levels across the monitoring sites in Germany. Most of the LP50 values are quite high. Considering damage addition within the context of MoA groups, the toxicity analysis of both MoA groups, using dimethoate for neuromuscular substances and propiconazole for sterol inhibition, resulted in lower LP50 values, suggesting reduced margins of safety for non-target organisms. At some monitoring sites, LP50 values fell below 100 and even below 10, indicating potential acute risks not captured by single compound toxicity analyses. These results provide an initial overview but will be refined by including more substances and MoA groups. A long-term objective is to link these results to community-level risk indicators such as the SPEAR index.

Disclaimer/Disclosure: This work was carried out in the framework of the European Partnership for the Assessment of Risks from Chemicals (PARC) and has received funding from the European Union's Horizon Europe research and innovation programme under Grant Agreement No 101057014.

4.04.P-Tu329 TKTD Models for Aquatic Primary Producers – A New SETAC Working Group

Udo Hommen[1]*, Annika Mangold-Doring*[2]*, Stefan Reichenberger*[3]*, Johannes Witt*[4] *and Cecilie Rendal*[5]*, (1)Fraunhofer Institute for Molecular Biology and Applied Ecology (IME), Germany, (2)Environmental Risk Assessment team, Wageningen University and Research (WUR), Wageningen, Netherlands, (3)knoell France SAS, France, (4)Bayer AG, Germany, (5)Syngenta, United Kingdom*

The use of toxicokinetic-toxicodynamic (TKTD) models to assess the effects of time-variable exposure of organisms to plant protection products is outlined in a Scientific Opinion of the EFSA PPR panel (2018). Since then, especially the GUTS model on lethal effects, is increasingly used. Some models are also available for assessing effects on the growth of algae or macrophytes, but a harmonized framework for calibration, validation and extrapolation of primary producer models does not exist yet.

A TKTD and growth model for the standard macrophyte test species *Lemna* sp. was developed by Schmitt et al. (2013) and subsequently refined and harmonized by the SETAC Lemna working group (Klein et al., 2022). The technical report is available on the SETAC website. As a follow-up activity, a new working group was established in 2024 with the aim to identify suitable workflows and measures for algae and macrophyte TKTD modelling in tier 2C (refined exposure experiments and modelling). In particular, the following objectives should be achieved in adherence to EFSA s Scientific Opinion on TKTD modelling (EFSA PPR panel, 2018) as much as possible but considering special properties of aquatic primary producers:

1) Development of a unified strategy for calibration and validation of TKTD models for aquatic primary producers

2) Development of a framework for generating moving time windows across FOCUS exposure series for use in Tier 2C assessments

3) Provision and ring testing of user-friendly open-source software solutions in the style of MOSAIC and

OpenGUTS
The working group has over 20 members and started to meet regularly since autumn 2024. The poster will present the current state of work and the working plan.

4.04.P-Tu330 A TKTD Module for BEEHAVEecotox – Combining BEEHAVEecotox and BeeGUTS
*Dominik Lammers, Thomas G. Preuss and **Vanessa Roeben**, Bayer AG, Germany*
Honey bees play a vital role in providing the ecosystem service of pollination to both wild plant species and cultivated crops, making them a crucial consideration in the environmental risk assessment of plant protection products in the European Union. In this context, mechanistic modeling has emerged as a powerful tool for predicting bee exposure and effects in the field, gaining increasing acceptance within the regulatory framework.
The BEEHAVEecotox model represents a significant advancement as the first honey bee model to mechanistically link realistic field exposure with subsequent effects on various levels of bee colony. Utilizing standard regulatory study data, the model derives dose-response functions for effects resulting from contact and oral exposure, while also accounting for larval mortality.
Concurrently, the development of the BeeGUTS model offers a TKTD (toxicokinetic-toxicodynamic) model for interpreting and extrapolating honey bee survival data. This model provides a cohesive framework that integrates the effects from acute contact, acute oral, and chronic oral studies into a unified set of parameters, considering toxicity as a process over time. This innovative approach moves beyond single point estimates of toxicity and exposure to establish a holistic link between exposure and effect.
Both models have undergone validation with independent datasets and have demonstrated strong predictive capabilities within their respective domains of applicability. Notably, the modular approach employed in the development of the BEEHAVEecotox model allows for the exchange or addition of modules as new knowledge becomes available.

In this presentation, we will unveil the initial results of integrating a new toxicity module into BEEHAVEecotox using BeeGUTS. The poster will shed light on the challenges and distinctions between the two approaches, while also comparing predicted results from semi-field studies.

4.04.P-Tu331 Applying a Toxicokinetic-Toxicodynamic Model to Risk Assessment of a Rooted Macrophyte, *Myriophyllum spicatum*
*Marina Lauck[1] and **Anastasia Del Signore**[2], (1)Corteva Agriscience, United States, (2)Corteva Agriscience, Germany*
There is growing interest in the use of modeling approaches to inform environmental risk assessment. Conventionally, lab-based environmental risk assessment studies test a gradient of concentrations to calculate dose response curves and inform risk to nontarget organisms. In assessing risk to aquatic plants, several model organisms are used, including *Lemna gibba*, a free-floating macrophyte, and *Myriophyllum spicatum*, a rooted macrophyte with high ecological relevance, where endpoints are based on effects on growth rate. However, lab-based studies are limited to specific environmental conditions and may not reflect the more complex conditions observed in the field. Additionally, traditional study designs may not adequately capture the relationship between molecules and their effects on an organism. Plant protection products aim to have low degradation half-lives and reduced environmental persistence, requiring lab-based studies to maintain artificially high and steady concentrations of a compound. In the field, exposure in aquatic environments is characterized by an initial pulse at the time of application and then a steady decline. Here, modeling allows for the extrapolation from lab-based conditions to more real-world scenarios, such as via Toxicokinetic-toxicodynamic (TKTD) models that describe species- and molecule-specific relationships.
We built on the TKTD model for *Lemna* and applied it to *Myriophyllum* and the interactions between its roots and the sediment. The model was calibrated and validated using laboratory and greenhouse studies, and outputs adequately reproduced observations. Using a rapidly degrading auxin herbicide as a case study, the model was applied to different chemical exposure scenarios reflective of expected environmental conditions. This application allows for a more holistic understanding of a chemical's potential influence on nontarget aquatic macrophytes and can provide additional information to apply to regulatory decision-making.

4.04.P-Tu332 Moving Towards Standardisation of Literature-Based Parametrisation of DEB Models for Regulatory Relevant Non-Target Arthropods: Insights from Four Case Studies

***Josef Koch**[1], Natalie Albrecht[2], Jana Gerhard[2], Kim Rakel, Ecotoxicology RWTH University[2], Heike Fremdt[3], Daniela Jans[3], Andre Gergs[3] and Thomas G. Preuss[3], (1)gaiac Research Institute, Aachen, Germany, (2)gaiac Research Institute, Germany, (3)Bayer AG, Germany*
In recent years, several regulatory guidance documents have endorsed the use of DEB-TKTD models (Dynamic-Energy-Budget based toxicokinetic-toxicodynamic models) to refine chronic pesticide risk assessment. These models allow both lethal and sublethal effects to be simulated as a function of constant or dynamic conditions of pesticide exposure and environmental factors like temperature. However, in order to calibrate such TKTD models to reproduce experimentally observed toxic effects adequately, at first the normal physiological behaviour of a species at unstressed control conditions must be explained well enough by the DEB part of the model. The Add-my-Pet repository provides many such models, although many regulatory relevant non-target arthropods (NTAs) are still missing. Furthermore, there is no prescribed procedure for how the data search for a new DEB model should be carried out and documented. In this study, we aimed to streamline this process by conducting a literature search for four terrestrial NTAs (*Typhlodromus pyri*, *Aphidius rhopalosiphi*, *Coccinella septempunctata*, and *Chrysoperla carnea*) according to the EFSA guidance on literature search, and provide documentation following the suggestions by the SETAC working group MAD. Subsequently, a DEB parametrisation was carried out for all four species, with particular attention being paid to the potential for standardisation on the one hand and the need for species-specific adaptations on the other. Three out of four species could be successfully parametrised in this way, while there were insufficient data for the last one (*T. pyri*). Overall, it was found that certain types of control data were replicated overabundantly in the literature, whereas data on the physical growth of the species were particularly scarce. Despite an attempt to use only existing model variants (towards standardisation), several modifications and model extensions were necessary to ensure the realism and usefulness of the models. These include a restructuring of typical life history processes in *C. septempunctata*, in which sexual maturation only begins after the pupa stage, as well as a new module for *A. rhopalosiphi* used to model its parasitisation rate as a function of reproductive investment, host type, host abundance, temperature, and timing during the reproductive phase. Both changes benefit from the modular nature of DEB models, and can be seen as extensions to the existing toolbox for DEB models.

Disclaimer/Disclosure: This study was funded by Bayer.

4.04.P-Tu333 Grassland as Surrogate Crop for Winter Cereals in Common Vole Field Effect Studies – Hypothesis Testing using Mechanistic Effect Modelling

***Oliver Jakoby**[1], Pernille Thorbek[2], Torben Wittwer[1], Lara Ibrahim[3], Katharina Ott[4], Tina Grimm[3] and Kai Ristau[4], (1)RIFCON GmbH, Germany, (2)BASF SE, Germany, (3)RIFCON GmbH, Hirschberg, Germany, (4)BASF SE, Germany*
Mechanistic effect modelling can benefit environmental risk assessments (ERA) in various ways. Mostly it is used to evaluate risk in realistic scenarios or compare mitigation options. It can also be used to evaluate and improve field effect study set-ups by comparing different virtual study designs. Field effect studies are among the higher tier refinement options of pesticide ERAs for small herbivorous mammals focussing on common voles. In these ERAs the crop of interest is usually no primary vole habitat. Field studies in such crops yield usually only low individual numbers, which makes it difficult to detect potential effects. Thus, a common approach is to perform those studies in more favourable habitats for voles as grassland as surrogate crop . Here, we investigate whether vole field effect studies conducted in grassland are a feasible and protective approach.
We used the spatially explicit individual-based model for the common vole, eVole, to analyse population dynamics in a landscape consisting of both winter cereal and grassland habitat. We investigated the spatio-temporal population dynamics and the effects of pesticide applications in either of the two habitats.
Our modelling study exemplifies that throughout the year population density was higher and individuals were more homogeneously distributed in grassland compared to cereals, where voles more likely occurred in the field edges. Under pesticide application the vole population in treated grassland was affected at lower application rates and led generally to larger magnitudes and longer durations of potential effects compared to treated cereals.
The results underpin the assumption that field effect studies conducted in grassland are sufficiently protective to cover the risk assessment in secondary habitats like yearly field crops. First, in grassland, voles are present all year round at higher densities than in cereals, which allows capturing more voles to better detect population level effects. Second, the effects themselves are larger for treatments applied in grassland compared to cereals as voles are more frequently affected in grassland due to their higher densities and because of higher crop interception in cereals, particularly at later crop development stages.

Overall, this study underlines the potential of ecological modelling to support ERA not only directly providing additional evidence for the ERA process, but also for evaluating, planning and designing higher tier field options.

4.04.P-Tu334 APODEMUS, a Population Model for the Wood Mouse: Transparent Conceptual Model Development with Stakeholder Involvement

*Alexander Singer[1], **Amelie Schmolke**[1], Lara Ibrahim[2], Oliver Jakoby[1], Tina Grimm[2], Felix von Blanckenhagen[3] and Nika Galic[4], (1)RIFCON GmbH, Germany, (2)RIFCON GmbH, Hirschberg, Germany, (3)Rifcon GmbH, Germany, (4)Syngenta Crop Protection AG, Switzerland*

The wood mouse, *Apodemus sylvaticus*, is the small mammalian omnivore focal species in the pesticide risk assessment scheme in Europe because the species occurs in agricultural landscapes across large parts of Europe and feeds on various diets. However, scenario-dependent individual exposure levels and potential population-level effects are challenging to assess in field exposure or effect studies. Simulation models can predict population-level effects from modelled life-cycle processes and individual-level exposure and effects. We present the concept for APODEMUS, A POpulation Dynamical spatially Explicit Model of the wood moUSe. Transparency is key in the devising of APODEMUS. Therefore, following best practices recommended in recent guidance documents by EFSA, we developed the conceptual model based on Pop-GUIDE. The Pop-GUIDE framework facilitates condensing all available knowledge and using it during the development of population models for risk assessment. For the conceptual model of APODEMUS, a comprehensive literature search and review provided the basis for the step-wise decisions leading to the conceptual model. In addition, these decisions were revised in a stakeholder workshop involving small mammal experts, risk assessors and regulators as well as ecological modellers. We will share insights from the conceptual model development and stakeholder involvement. This experience supported suggestions for better embedding Pop-GUIDE in the European risk assessment of small mammals. We demonstrate how a systematic development of a population model with continued stakeholder support can lead to a transparent tool for higher-tier risk assessments to improve risk assessment options and reliability.

4.04.P-Tu335 Individual-Based Models (IBMs) for Fish in the Regulatory Risk Assessment of Plant Protection Products - A Practical Method

***Alice Tagliati** and Charles Hazlerigg, Enviresearch Ltd., United Kingdom*

The current EFSA aquatic guidance document (2013) states that population models have great potential for use in the risk assessment of plant protection products (PPPs); however they have rarely been applied in a regulatory context. Specifically, in the risk assessment of PPPs, population models are included as a Tier III refinement option, i.e., to assess whether the effects observed at organism-level endpoints in standard OECD studies are expected to have a significant effect on populations under realistic exposure conditions. Population models do so by integrating aspects of life-history (e.g. reproductive rate), interactions between individuals (e.g. competition and predation) and population-level processes (e.g. density dependence) within a dynamic environment. In addition to predicting a pesticide risk, population models may also be used to improve our understanding of experimental data, identify focal (vulnerable) species, investigate the likelihood of population recovery and to assess natural variation in population abundance. This poster presents a case study to outline a stepwise approach for practically using Individual-Based Models (IBMs) for fish in a PPP risk assessment context, highlighting the critical decisions that need to be made regarding the modelling process. First, the species, model and scenario choice will be discussed. Then the implementation of exposure and effects and a simulation experiment will be presented, along with the assessment criteria for determining significant population level effects. Finally, the reporting recommended for a regulatory submission to facilitate an efficient evaluation will be described. Further work from the scientific community is still needed to better define models, focal species and scenarios for different uses in environmental risk assessments, as well as to better understand model outcomes. However, we believe there is currently a workable method for the use of population modelling in the risk assessment of PPPs by adapting off-the-shelf models.

4.04.P-Tu336 Determine Endpoints on Visual Effects for Terrestrial Plant (NTTP) Risk Assessment using Determinstic and Stochastic (Bayesian) Statistics

*Carmen Schweikert[1], Cecile Perillon[2] and **Thomas Graff**[3], (1)IV 1.3-1, German Environment Agency (UBA), Dessau-Rosslau, Germany, (2)German Environment Agency (UBA), Dessau-Rosslau, Germany, (3)German Environment Agency (UBA), Germany*

For the authorization of plant protection products (PPP) in the EU the risk of negative impacts on non-target terrestrial plant (NTTP) is evaluated based on ER50 values for emergence, biomass, shoot length, and visually assessed phytotoxic effects observed in greenhouse studies (OECD 208 and OECD 227). Given the prerequisites for statistical evaluation of binomial distributed data from a dose/effect curve, the ER50 value can be derived for each of these effect parameters.
For visual phytotoxicity often scoring systems are used encompassing percentage ranges of the effects observed. One method (method 1) to deal with these ranges is firstly setting the value to the midpoint of its range and then using deterministic methods to derive the ER50 values (e.g., using R-package drc). For example, the midpoint 50% effect is used for the score 40-60% effect visually observed. Another method (method 2) is based on the Bayesian concept, where the effect range of the scores used is directly integrated in the statistical evaluation (e.g., R-package rjags). The authors compare the two approaches and in addition, with a third approach (method 3) where the concept of censored data (e.g. observed effects are > 30%) is integrated into the stochastic method (Bayes). The produced data sets were systematic aggregated to different score systems (ten, five, three) with equidistant and with unequal score levels, to understand the influence of the three modelling approaches on the effect value ER50 and the uncertainty (CI). The quantification of the midpoint model of the deterministic concept (method 1) and the Bayesian stochastic model using observation intervals (method 2) could give a better approximation than the Bayesian model with censored data (method 3), particularly of low score levels.
We want to share this comparison to facilitate the determination of robust endpoints for visual phytotoxicity from the studies used to evaluate the risk of PPP to NTTPs and to thereby support the evaluation of such data for PPP risk assessment.

4.04.P-Tu337 Tailored Test Designs to Address Actual Challenges Through Mechanistic Modeling – A Case Study for Temperature Dependent Effects of Imidacloprid

Silke Classen[1]*, Daniel Burkow*[2]*, Andre Gergs*[2]*, Daniel Gerth*[3] *and Jutta Hager*[2]*, (1)gaiac Research Institute, Germany, (2)Bayer AG, Germany, (3)gaiac Reseach Institute, Germany*

In chemical risk assessment, extrapolations from laboratory tests to more realistic conditions are essential to address the effects of pesticides on individuals and populations under field conditions. In this context modelling approaches gained in relevance and acceptance to answer questions that cannot be addressed directly by experimental work. However, to further improve the response capability and thus the degree of reality these models can cover, it is important to design experimental studies that close common gaps in model parametrization and validation. This is best achieved by close cooperation of modelers, experimental ecotoxicologists, and ecologists.
Temperature dependence of effects is an example of an important factor which modulates the sensitivity of organisms to toxicants and must be considered to increase realism. Mechanistic effect models allow for the extrapolation and prediction of untested temperature scenarios (higher, lower, or variable) from models parameterized on standard test conditions.
Here, we present a case study with a series of tailored experiments for two insects, *Cloeon dipterum* and *Chironomus riparius*. A primary goal of this study was to obtain data on physiological temperature dependencies that could be applied to toxicokinetic toxicodynamic (TKTD) parameters in a General Unified Threshold model of Survival (GUTS) for lethal effects. Similar test designs were implemented for both species with a range of temperatures and exposure scenarios.
In a first step, effects at a standard test temperature (20° C) under chronic exposure were used to calibrate the GUTS model for both species separately. An Arrhenius function was added to the standard GUTS parameterization to predict temperature dependent rates for higher and lower temperatures. This model was able to predict effects that our experiments observed under the different temperatures and exposure conditions. The combination of mechanistic model and tailored experimental design proved that observed temperature dependency on physiological toxicity parameters and survival patterns can be predicted for a more realistic environmental risk assessment.

4.04.P-Tu338 How to Determine if an Effect in a Population Model Should be Considered "Adverse"?

Alice Tagliati[1]*, Thomas G. Preuss*[2] *and Charles Hazlerigg*[1]*, (1)Enviresearch Ltd., United Kingdom, (2)Bayer AG, Germany*

In recent years population models have been proposed as a potential tool for assessing the relevance of the population level effects for non-target organisms in a wide range of regulatory contexts, ranging from the ecotoxicological risk assessments of pesticides to the hazard assessment of endocrine disruptors. However, the thresholds to define whether an effect is truly adverse are rarely detailed within the guidance documents. Traditional statistical methods for determining significant effects are not appropriate for population models as replication may be easily increased by performing more simulations and therefore change the value for statistical significance. In the academic literature, a priori default percentages of deviation from control simulations (e.g. 5-15%) have been used as the threshold for population response. However, this approach fails to consider the Normal Operating Range of the population resulting in a potentially different level of protection depending on the species being modelled. More recently, the updated EFSA Birds and Mammals guidance document (2023) proposed two assessment criteria for determining whether a population response is observed: (i) the mean of the exposed population falls below the lower 95th percentile of the control and (ii) the lower 95th percentile of the exposed population is consistently lower than the lower 95th percentile of the control. The EFSA criteria are promising because they avoid the use of arbitrary values set a priori by considering the actual dynamics of the population, and by using percentiles resist the influence of increasing model runs to change statistical thresholds. However, we found criterion 2 to be too strict and creating too many false positives. Comparisons of multiple sets of control simulations led to failure of this criterion and show of adverse effect where none should be present. Furthermore, we show that the strict interpretation of the assessment criteria meant that 100% of the scenarios exposed to a pesticide tested with different fish Individual-Based Models failed this second criterion (i.e. a population response observed in all cases). Further work is therefore required in order to establish a second criteria that is scientifically robust and consistent with the level of protection offered by criterion 1 before being used to assess population model outcomes. We will explore and present potential methods for determining whether a model outcome should be considered adverse.

4.04.P-Tu339 Spatial Heterogeneity of Environmental Exposure and Risk Assessment at Different Scales – Linking Exposure and Effects (ELINK-2)

*Dirk Nickisch[1], Bas Buddendorf[2], Nika Galic[3], Bernhard Gottesbueren[4], Sebastian Multsch[5], Thomas G. Preuss[6], Hendrik Rathjens[7], Vanessa Roeben[6], **Oliver Jakoby**[8] and Carola Schriever[5], (1) RIFCON GmbH, Germany, (2)WUR, Netherlands, (3)Syngenta, United Kingdom, (4)make-sense consulting, Germany, (5)BASF SE, Germany, (6)Bayer AG, Germany, (7)Stone Environmental, United States, (8)RIFCON GmbH, Germany*

In 2007, the ELINK workshop convened experts in exposure and effect assessment to explore the impact of time-varying exposure patterns on aquatic pesticide risk assessments. Recently, the need for a new series of ELINK workshops was recognized and initiated to bring together specialists to advance the integration of exposure and effect modeling, and to develop environmental scenarios for risk assessment that consider spatial heterogeneity at various scales.

During the ELINK-2 workshop series, five working groups will discuss the implications of spatial heterogeneity at different scales:

- EL-LA - Aqua: Large scale landscape modeling related to aquatic non-target organisms.
- EL-LA - Terra: Large scale landscape modeling related to terrestrial non-target organisms.
- EL-ME: Medium/field scale modeling at the edge-of-field and field scale.
- EL-SA: Small scale modeling at the plant/soil interface scale.
- EL-GIS: Generic methodology of GIS data processing related to various scales.

The discussions will be based on case studies.

The most pressing issues for spatial modelling in European risk assessment identified in the first meetings of the 50-member working group are:

- Scenario development
- Geodata/Data availability
- Acceptability to authorities
- NTA risk assessment
- Test data sets/validation of models
- Complexity vs. pragmatism
- Ecological realism
- Ecologizing the exposure scenarios
- Variability/Uncertainty
- Quantifying the advantages of spatial modeling

4.04.P-Tu340 Advantages of Modeling Dose Response Mechanistically

*Zhenglei Gao[1], Julian Heinrich[2], Andre Gergs[2], **Daniel Burkow**[2] and Thomas G. Preuss[2], (1)Data Science, Bayer AG, Germany, (2)Bayer AG, Germany*

Environmental Risk Assessment (ERA) is based on measures or estimates of endpoints for exposure and hazard. Hazard assessment endpoints are based on statistical tests to estimate LOECs (Lowest Observed Effect Concentration) or dose response modelling for ECx (Concentration for x% Effect) calculations. Most, if not all, studies generate more data than required for this endpoint calculation, so only a very small fraction of the generated data is used to estimate these endpoints, e.g., only the last day of a chronic 21-day chronic daphnia test. We compare conventional dose response methods to mechanistic TKTD (toxicokinetic-toxicodynamic) model approaches to derive the same endpoints. Examples demonstrate cases where mechanistic models provide deeper understanding of the ecotoxicological risk. We suggest that, where possible, collecting sufficient data from primary studies to capture the necessary endpoints for TKTD modeling can only improve understanding of and decisions on ERA outcomes.

4.05 Non-Target Arthropods: A New European Risk Assessment Guidance on the Rise

4.05.T-01 Insect Decline – Evaluation of Potential Drivers of a Complex Phenomenon

***Michael E. Greve**, Michael Thomas Marx, Sascha Eilmus, Matthias Ernst, John Herrmann, Christian Baden and Christian Maus, Bayer AG, Germany*

Insect decline is a global environmental issue with far-reaching ecological consequences. Despite its significance, the causes of this phenomenon remain unclear due to the complexity of contributing factors and a lack of comprehensive historical data. This study aims to identify key drivers of insect biomass decline observed over 33 years in Western Germany by analyzing correlations between insect population trends and various potential environmental and anthropogenic factors such as changes in landscape structure and land management practices.

To address this challenge, we used long-term data from statistical records and market surveys, to track changes in landscape structure, land use, and agricultural practices. Key parameters included urbanization, grassland management, cropping practices, pesticide use, and climate factors.

Our results suggest that habitat loss and deterioration driven by land-use change and land management intensification are primary contributors to insect decline. Urban expansion significantly reduced insect habitats, while shifts in arable land towards bioenergy and feed crop cultivation, influenced by dairy farming intensification and renewable energy policies, exacerbated the trend. Notably, no direct links were found between insect decline and climate or pesticide use.

These findings suggest that balancing extensively and intensively managed areas, conserving natural habitats, and enhancing landscape structural diversity are critical to mitigating insect decline. Thus, the study offers insights into the drivers of insect decline and provides a foundation for targeted conservation strategies in Central Europe and beyond.

Disclaimer/Disclosure: This work was funded by Bayer AG.

4.05.T-02 Plant Protection Products and Ecosystem Services: Identifying Vulnerable Non-Target Arthropods and Linking Effects to Ecological Function

***Lorraine Maltby**[1], Leonhard Urs Bürger[2], Steven Droge[3], Daniel Paredes[4], Jose Paulo Sousa[5], Grzegorz Sylwester Sowa[6], Louise Wipfler[7] and Andreas Focks[8], (1)School of Biosciences, University of Sheffield, United Kingdom, (2)Institute of Mathematics, Osnabrück University, Germany, (3)Wageningen University and Research (WUR), Netherlands, (4)University of Coimbra, Portugal, (5)University of Coimbra, Coimbra, Portugal, (6)School of Biosciences, University of Sheffield, Sheffield, United Kingdom, (7)Environmental Risk Assessment, Wageningen University and Research (WUR), Wageningen, Netherlands, (8)Osnabruck University, Germany*

The Guidance Document on Terrestrial Ecotoxicology (SANCO/10329/2002) is 22 years old and the European Commission has mandated the European Food Safety Authority (EFSA) to review the guidance for non-target arthropods (NTAs), in-soil organisms and non-target terrestrial plants. As part of this process the AENEAS project was initiated to advance the environmental risk assessment of NTAs by accounting for the impact of plant protection products (PPPs) on ecosystem services and ecological functions. Here we describe the implementation of a protocol to link PPPs effects on NTAs to potential impacts on key ecosystem services. A database of NTA species pivotal for pest control and pollination, sampled from six focal annual crops (wheat, barley, maize, oilseed rape, potato, beet) and three focal perennial crops (olive, apple, grape) across 37 EU members states was compiled. Representative NTA groups contributing to pest control and pollination across crop type and across EU zones were identified. This analysis was performed separately for ground-dwelling and foliar pest control NTAs. Trait-based vulnerability analyses were used to identify vulnerable NTA within these representative families. The sensitivity of vulnerable representative NTA families to three insecticides was compared and chemical-specific vulnerability indices were calculated. Population modelling platforms (ALMaSS, Bumble-BEEHAVE) were used to assess the impact of PPP exposure on the population dynamics of vulnerable taxa within agricultural landscapes. The PPP effects on population abundance were translated to ecosystem functions using functional responses for pest control and by simulated flower visits for pollination. Landscape-level assessments considered subpopulation impacts (in crop, off crop) and landscape heterogeneity (crop diversity and proportion of natural habitat). Standard test species do not belong to the most vulnerable representative pest control or pollination NTA families and they may be less sensitive to insecticides than members of vulnerable representative NTA families for pest control and for pollination. Population modelling platforms show great potential for assessing the impact of PPP exposure on the population dynamics of vulnerable taxa within agricultural landscapes of different composition. However, limitations of both the population modelling platforms used currently limits the potential use of the protocol in regulatory risk assessment.

Disclaimer/Disclosure: AENEAS was funded by the European Food Safety Authority.

4.05.T-03 A TKTD Data Interpretation of Non-Target Arthropod Tests

Jan Baas[1], *Sonja Braaker*[2], *Charlotte Elston*[3], *Heike Fremdt*[4], *Thomas G. Preuss*[4] *and Ivo Roessink*[5], *(1)Wageningen University and Research (WUR), Netherlands, (2)BASF, France, (3)Syngenta, United Kingdom, (4)Bayer AG, Germany, (5)Wageningen University and Research (WUR), Wageningen, Netherlands*

Tests with non-target arthropods (NTA) are part of the requirements in the authorisation process for the registration of pesticides in Europe. These tests consist of exposing the predatory mite *Typhlodromus pyri* and the parasitic wasp *Aphidius rhopalosiphi* on treated surfaces, e.g., a glass plate in Tier 1 testing and treated leaves or plants in Tier 2 testing. This experimental setup should approximate the potential exposure of NTAs in the field.

The result of the tests is the lethal application rate that kills 50% of the organisms (the LR50), which is calculated from the dose-response curve from one particular observation timepoint of the test. We were interested in the suitability of these data for TKTD analysis and if this then could be used to integrate the glassplate test with the leaf tests, within one consistent framework. A total of 38 individual tests, comprising tests with individual insecticides, herbicides and fungicides, were available for this TKTD data interpretation.

In most cases the data consisted of both a glass plate test and a leaf test for both *T. pyri* and *A. rhopalosiphum*. In general, species appear to be less sensitive in the leave tests than in the glassplate tests. This is likely caused by the altered exposure conditions in the leaf tests. The tests were carried out following the standard protocols, and it should be noted that these were not designed to carry out a data interpretation with a TKTD model. In most cases only 2 or 3 observations on effects in time were available, which is limited from a TKTD data interpretation perspective. Due to inconsistencies in the number of dead individuals over time, lack of observations on effects at intermediate points in time or inconsistent dose-response curves, some tests were not suitable for use in the TKTD approach. This left 26 tests (13 combinations of glass plate tests and leaf tests) available where the glass plate test could be used for an estimation of the decline of the concentration on the leaves.

The most important take-home message from this data evaluation is that when intermediate time-points with observations on effects are available and the result of the test is consistent, the standard tests can be interpreted with a TKTD model and that the result of the glass-plate test and the leaf test can indeed be integrated within one consistent framework.

4.05.T-04 Effects of Drift Exposure on Non-Target Arthropods: Insights from a Small-Scale Movement Model

Matthias Becher[1], *Andrew C. Chapple*[2], *Heike Fremdt*[2], *Rena Jutta Irene Isemer*[2], *Oliver Jakoby*[1], *Edward Pilling*[3], ***Amelie Schmolke***[1], *Carola Schriever*[4], *Pernille Thorbek*[5] *and Thomas G. Preuss*[2], *(1)RIFCON GmbH, Germany, (2)Bayer AG, Germany, (3)Corteva Agriscience, United Kingdom, (4)BASF SE, Germany, (5)Apd/EE, BASF plc, United Kingdom*

The European Food Safety Authority is revising its guidance on pesticide risk assessment for non-target arthropods (NTAs). This group encompasses a wide range of species with diverse behaviours and habitat

preferences, affecting their exposure potential. For NTAs in the off-field, usually the exposure via spray drift is considered as the main exposure route.
We developed a spatially explicit, individual-based model to simulate NTA movement in a given off-field structure with a spatial and temporal explicit exposure pattern. As an example, we use here exposure in a 2 x 2 m hedge area adjacent to treated crops. Pesticide residues, defined by three gradients, dissipate over time. NTAs are characterized by traits such as body size, movement speed, and preferred locations. In this example the model runs for 10 days with 10-minute time steps, simulating their movement as an uncorrelated random walk. NTAs pick up pesticides based on residue levels and contact area.
Simulations included four NTA trait groups: Aphidius-type (small parasitic wasps), Carabid-type (medium-sized ground beetles), Pisauridae-type (medium-sized spiders) and Typhlodromus-type (small predatory mites).
Residues were defined via three different gradients: "Field" side (highest contamination on the side facing the field), "Field and Top" (highest contamination in the top corner adjacent to the field and "Uniform" (even pesticide distribution).
Pesticide uptake varied significantly among trait groups and residue gradients. Due to higher body surface to volume ratios, smaller NTAs (Aphidius-type, Typhlodromus-type) accumulated more pesticides relative to body weight than larger NTAs (Pisauridae-type, Carabid-type). Behavioural preferences also influenced exposure: Pisauridae-type NTAs (randomly moving across the whole simulated area) showed no significant difference in exposure across gradients whereas Carabid-type NTAs (only located on the ground) were almost exclusively exposed in the Uniform gradient.
Overall, we show that NTA movement and behaviour along with residue distribution significantly influence exposure of the individuals in a population. Realistic risk assessments should consider these factors rather than assuming average exposure. This study shows again that mechanistic models can help us understand the complex interactions between behaviour and residue levels and improve our ability to predict risks of pesticide exposure to NTAs.

4.05.T-05 Developing a Framework for Identifying Sentinel Taxa for the Non-Target Arthropod Risk Assessment in Europe Using Field Effect Studies

*Edward Pilling[1], **Charlotte Elston**[2], Frank Bakker[3] and Saskia Aldershof[4], (1)Corteva Agriscience, United Kingdom, (2)Syngenta, United Kingdom, (3)Bakker Onderzoeks Beheer, Netherlands, (4)Bioresearch and Evaluation, Netherlands*

Non-target arthropod (NTA) field studies represent the highest tier of study available in the tiered regulatory process. Field studies have the highest degree of realism, but also a high degree of variability and unlike higher tier bee studies, NTA field studies are conducted with naturally occurring populations of multiple species. This results in large, complex datasets involving hundreds of different taxa with differing compositions and abundances, as a result these studies can be difficult to interpret and ascertain what is a potential effect of a plant protection product (PPP) on populations and communities versus natural background and seasonal variability.
In addition, the current NTA risk assessment in Europe (ESCORT 2) and Terrestrial Guidance Document (SANCO/10329/2002 rev 2 final) are currently undergoing revision meaning there are discussions ongoing in terms of what to protect, where to protect it, over what time period and with what degree of certainty (Specific Protection Goals SPGs).
The compiled NTA field effect database and its analysis represent a powerful resource for the development of the future risk assessment scheme for NTAs. In the first instance, it allows to derive recommendations for future field trial design and for its data analysis and interpretation. Further, the identification of sentinel taxa is not only relevant for the evaluation of field effect studies but also for the development of ecological models. Considering the spatial and temporal scale of NTA field studies and the number of taxa that are observed, ecological models are expected to gain in importance in the future NTA higher tier risk assessment in Europe. As it will not be feasible to develop models for all taxa potentially present in an area, a framework to understand the key representative taxa is therefore essential for model development. In addition, the database is valuable for analysing the spatial and temporal variability of taxa or ecological traits, thus making it a valuable resource for establishment of Normal Operating Ranges or/and Specific Protection Goals.

4.05.P Non-Target Arthropods: A New European Risk Assessment Guidance on the Rise

4.05.P-Mo315 The Effect of Targeted Vegetation Sampling on Diversity and Variation of Mite Populations

*Mink van Meijer, **Melanie Hagen-Kissling**, Farid Faraji, Paul Hoekstra and Bogdan Dehelean, Eurofins MITOX B.V., Netherlands*

In ecological risk assessments (ERA) for plant protection products (PPP) mites are a key focus group, particularly in higher tier field studies involving non-target arthropods (NTA). Their composition (diversity and abundance) in the field is influenced by various abiotic and biotic factors, such as temperature, food availability, presence of predators or plant species composition (especially for herbivorous mites). As a result, high spatial variation is regularly observed, posing challenges for data analysis. In higher tier field studies in off-crop meadow habitats, mites are typically collected from vegetation samples, which involves indiscriminative sampling of all plant species (and the mites residing on them) from a random location of a defined size in the plot.

Here, we investigate whether targeted sampling (focusing on mites from target plant species with particular characteristics) can produce less variable data sets compared to the conventional indiscriminative approach (described above). Additionally, we assess how representative the mite community obtained through targeted sampling is in comparison to that obtained through indiscriminative sampling.

To explore the influence of plant type on mite composition in meadow habitats, we examined the effects of plant characteristics on mite diversity and abundance. We compared the mite composition on monocot plants versus dicot plants, and on hairy versus glabrous plants. Our focus was not only on differences in mite community composition between these plant groups, but also on the role of plant characteristics in reducing spatial variation in mite composition.

Our findings revealed no significant difference in mite diversity between monocot and dicot plants. However, significantly higher numbers of mites were found on hairy plants compared to glabrous plants. Moreover, mite abundance data from hairy plants exhibited less spatial variation between plots than data from glabrous plants.

These results suggest that targeted mite sampling could be a promising approach for higher-tier NTA field studies. It may (1) yield a comprehensive mite data set comparable to that obtained through indiscriminative sampling while (2) exhibiting reduced spatial variation, thereby providing a more robust basis for statistical analysis of PPP effects on mite populations and communities.

4.05.P-Mo316 Non-Target Arthropods: Effect of Sampling Effort on the Data Quality in Higher-Tier Field Studies

***Melanie Hagen-Kissling**[1], Bogdan Dehelean[2] and Josep Roig Garriga[3], (1)Eurofins MITOX B.V., Germany, (2)Eurofins MITOX B.V., Netherlands, (3)Eurofins MITOX FOPSE, France*

In higher tier field studies conducted to assess the effect of plant protection products (PPP) on non-target arthropods (NTA), the composition of the arthropod s community is influenced by several biotic and abiotic factors (e.g., food availability, predator prey interactions, etc.) on different spatial and temporal scales. For a good risk assessment, it is necessary to sample a representative proportion of the NTA community in terms of diversity and abundance, the latter having a big impact on the quality of the data analysis. However, there is a trade-off concerning the sampling effort: While data quality increases with increasing sampling effort, the feasibility of a study (field size, workload, costs) decreases.

Usually, in NTA field studies, four replicates per treatment are used. Here, we investigate how sampling effort affects (1) the composition of NTA (diversity and abundance) and (2) the number of taxa in a data set. For this study, we compare data sets of higher-tier NTA field studies with replicate numbers ranging from 3-5 (for off-crop) and from 2-4 for apple full fauna studies. We (3) relate the identity of those taxa, which were abundant enough to be included in population level analyses, to the list of taxa, which are supposed to be included in such studies according to De Jong et al. (2010). Special focus is put on the effect of the replicate number on the variability, and thus robustness, of the data sets.

4.05.P-Mo317 Non-Target Arthropods: Differences in Sensitivity to Pesticide Treatment In-Field vs. Off-Crop?

***Melanie Hagen-Kissling**, Livia De Felici, Julia Friman and Bogdan Dehelean, Eurofins MITOX B.V., Netherlands*

Higher tier NTA studies measure the responses of local communities to the exposure of a plant protection product in highly complex natural systems in contrast to lower tier lab studies, where experiments are conducted under predefined conditions. These natural systems are complex, and NTA communities are shaped by biotic and abiotic factors, which increase the variability in the system. Consequently, several factors could influence the response of the arthropods to the pesticide exposure. Habitat structure and condition (e.g., vegetation cover), abiotic factors (e.g., temperature, humidity), exposure routes and the

biology of the arthropods (e.g., habitat preference, feeding strategy) could affect such differences in response.
In our experiments, we see species belonging to certain families of spiders (Araneae) and beetles (Coleoptera) responding differently to the treatment with plant protection products, which cannot be explained by the arthropods physiology, only. The phenomenon could be caused by long term exposure of different types of pesticides or by the differences in structure, abundance, and diversity of arthropod communities from different habitats.
Here, we investigate if the differences observed in the effect of the application of plant protection products on closely related taxa is correlated with abiotic factors (e.g., temperature, humidity) or habitat structure (off-crop vs in-field).

4.05.P-Mo318 Proposing Data Quality Criteria for Environmental Stressor Identification on Insect Biodiversity

*Hendrik Rathjens[1], Dwayne R.J. Moore[2], Oliver Korner[3], **Carola Schriever**[4] and Sophia Mullner[5], (1)Stone Environmental, Austria, (2)Stone Environmental, United States, (3)ADAMA Deutschland GmbH, Germany, (4)BASF SE, Germany, (5)Plant Care Industries Associations (IVA), Germany*

The German Environment Agency (Umweltbundesamt UBA), in collaboration with academic partners, conducted a monitoring program on small agricultural streams across Germany. The final campaign report concluded that the detected concentrations of pesticide active substances are the dominant stressor for vulnerable insects and that the current regulatory framework for pesticides in Germany is not sufficiently protective for aquatic macroinvertebrate communities. The authors attributed the potential decline of insect biodiversity to pesticide pressure based on a multiple linear regression analysis. We critically reviewed these conclusions by analyzing the methods applied using the raw data that are accessible on Pangaea. Our investigation into data consistency and methodologies revealed discrepancies that challenge the original findings. Specifically, we found inconsistencies and a lack of transparency in data processing and gap-filling practices. Moreover, discrepancies in the temporal alignment of data collection across different parameters suggest potential flaws in the multiple linear regression analysis. We further identified methodological issues in the determination and interpretation of the pesticide pressure index TUmax. Additionally, our critique questions the reliance on single-value biodiversity indices like SPEARpesticides over the nuanced insights that multivariate analysis offers. These shortcomings undermine the reported effects of pesticide stressors on macroinvertebrate communities. We will propose data quality criteria that will support securing an appropriate level of data consistency in environmental data for the purpose of identifying primary environmental stressors on biodiversity

4.05.P-Mo319 Establishing Normal Operating Ranges of Key Non-Target Arthropod Taxa: Comparison of Approaches and Taxonomic Resolution

*Peter Vermeiren[1], **Oliver Jakoby**[2], Edward Pilling[3], Charlotte Elston[4], Michael E. Greve[5], Thomas G. Preuss[6], Pernille Thorbek[7] and Nika Galic[4], (1)RIFCON GmbH, Germany, (2)RIFCON GmbH, Germany, (3)Corteva Agriscience, United Kingdom, (4)Syngenta, United Kingdom, (5)Bayer AG, United States, (6)Bayer AG, Research Triangle Park, United States, (7)BASF, Research Triangle Park, United States*

A normal operating range (NOR) describes variability in a system property, for instance, it can represent variability in individual properties such as body sizes, or variability in a population property such as in abundance or biomass. The latter is of specific interest for pesticide risk assessment for Non-Target Arthropods (NTAs) because NORs are increasingly used to inform effect acceptability thresholds. However, there is currently no scientific literature or guidance document on appropriate approaches for determining NORs in a regulatory context of environmental risk assessment in Europe. However, data from industry field studies (generic and control replicates) and data extracted from peer-reviewed literature are a source of relevant information. Such datasets can support quantifying the magnitude of variability across relevant contexts (spatial, temporal) as well as sources of variability. This can then inform ecological (mechanistic effect) models that need to include appropriate sources of variability, so they are fit for purpose of NOR determinations.
In this study we look into a dataset consisting of a diverse group of species the non-target arthropods to identify appropriate approaches to analysing multi-species assemblage data in a way that can be used for operational NORs in a regulatory context of pesticide risk assessment. The dataset includes more than 90 generic and field effect studies conducted by industry. Both single species and higher taxonomic groupings are analysed to better compare variability in single species and in broader taxonomic groups . Here we present and discuss the conceptual approach to analyse and derive NORs from such

comprehensive, yet complex datasets, and illustrate preliminary findings in relation to their interpretation in a risk assessment context.

4.05.P-Mo320 The Impact of Selected Plant Protection Products on Two Coleoptera Species: *Aleochara bilineata* and *Poecilus cupreus*

Pawel Pieczka*, Magdalena Czarnynoga and Malgorzata Gorska, lukasiewicz-IPO Branch Pszczyna, Poland*

Despite the positive effects of pesticides in crop protection, there are significant risks associated with the detrimental impact of chemical substances on beneficial organisms that are naturally present in the environment. The aim of this project was to assess the impact of selected pesticides on two beneficial species of beetles: *Aleochara bilineata* and *Poecilus cupreus*. Both species were chosen as indicator organisms in the registration studies for chemical substances.

Since *A. bilineata* and *P. cupreus* have different lifestyles and life cycles, the studies are conducted in distinct ways, and various parameters are assessed to understand how these chemicals may affect them. The larvae of *A. bilineata* parasitize dipteran pupae to mature into adults; therefore, the studies focus on assessing the reproduction rates of these beetles and the potential mortality of adults when exposed to chemicals. In experiments involving *P. cupreus*, both adult mortality and their consumption of dipteran pupae are evaluated, as this species acts as a predator.

In the studies conducted as part of this project, three active substances commonly used in agricultural practices were applied: trinexapac-ethyl (a growth regulator), terbuthylazine (a herbicide) and deltamethrin (an insecticide). Simultaneously, in each test, the concurrent control group was prepared. Dimethoate was used as a reference material to verify the sensitivity of the organisms. The studies were conducted in the form of limit tests, which assessed a single concentration of each substance corresponding to field application rates.

No significant effects of trinexapac-ethyl and terbuthylazine were observed, both in terms of the reproductive output of *A. bilineata* compared to the control group and concerning the mortality and food consumption of *P. cupreus*. Deltamethrin showed varied toxicity to the tested organisms, depending on the field application rate. Dimethoate, as a toxic reference, confirmed appropriate sensitivity of both species of beetles to the chemical substances.

The results of the studies demonstrate selective responsiveness of organisms to different active substances and their concentrations, suggesting that various compounds can affect non-target organisms in species-specific ways.

4.05.P-Mo321 Moving Forward on NTA ERA: Contributions to Assessing the Inter-Species Sensitivity to Insecticides

*Artur Miguel Paiva Sarmento[1], Mykola Rasko[1], Antonio Cubells[1], Maria Mendes[1], Angel Plata[1], **Steven Droge**[2], Dick Belgers[2], Nina Jansen[2], Kas Swinkels[2], Louise Wipfler[2] and Jose Paulo Sousa[1], (1)Centre for Functional Ecology, Associate Laboratory TERRA, Department of Life Sciences, University of Coimbra, Portugal, (2)Team Environmental Risk Assessment, Wageningen Environmental Research, Wageningen University and Research, Netherlands*

The assessment of the environmental safety of plant protection products (PPPs) in Europe includes the risk to terrestrial non-target arthropods (NTAs). As a data requirement in the first tier assessment, effect studies with two beneficial NTA species - the parasitic wasp *Aphidius rhopalosiphi* and the predatory mite *Typhlodromus pyri* - must be performed. Nonetheless, there has been a growing discussion if the current first-tier effect assessment sufficiently protects all vulnerable key driver NTA species in the field. Additionally, the EFSA Panel on Plant Protection Products and their Residues defended that to reduce the uncertainty of the tier 1 risk prediction, test species should encompass taxonomic groups expected to show different sensitivity. A series of standard test protocols for different species of distinct trophic groups predators, pollinators and parasitoids have been published. However, due to the inconsistency in the testing methods developed, it is difficult to draw comparisons across species. One of the objectives of the AENEAS project (OC/EFSA/ED/2021/02) is to gain knowledge on the sensitivity of species representing the most vulnerable families of NTAs (key drivers for pest control and pollination) to PPPs. For that purpose, 16 NTA species were selected to be exposed to three commercially available formulations of insecticides with different modes of action - lambda-cyhalothrin, flupyradifurone and cyantraniliprole - via a single overspray application. Effects (mortality and abnormal behaviors) were assessed 4h after exposure and then each 24h until the end of the test, for a minimum of 48h. Medium Lethal Rates (LR50) for 24 and 48h were derived, when possible, for each tested species per product, using the software PriProbit (Sakuma, 1998), and a graphical representation of those values was depicted via Species Sensitivity Distribution (SSD) curves, using the software ETX (RIVM, 2004). For the species already tested (9 out of 16), Karate Garden (a.i. lambda-cyhalothrin) was consistently the most toxic product, with exception of *A. rhopalosiphi* which presented a similar sensitivity to Mainspring (a.i. cyantraniliprole). For the three insecticide formulations, one of the least sensitive tested species was constantly *Chrysoperla carnea*. Furthermore, it is relevant to highlight that at least one of the species required in the first tier - *T. pyri* and *A. rhopalosiphi* - was one of the most sensitive species for the insecticides tested.

4.05.P-Mo322 How Do Landscape Compositions Influence Pesticide Effects in Landscape Models?
***Leonhard Urs Bürger**[1], Grzegorz Sylwester Sowa[2], Lorraine Maltby[2], Daniel Paredes Llanes[3] and Andreas Focks[4], (1)Institute of Mathematics, Osnabrück University, Germany, (2)School of Biosciences, University of Sheffield, United Kingdom, (3)CFE Centre for Functional Ecology, University of Coimbra, Portugal, (4)Osanbruck University, Germany*
Because pesticides are potentially harmful for organisms they were not intended to harm, environmental risk assessment (ERA) procedures were introduced to evaluate and mitigate that risk. These procedures span from tests on individuals to (semi-)fields experiments. Conducting risk assessment experiments on whole landscapes is not feasible for obvious reasons, but ensuring a healthy invertebrate population in the whole landscape is the ultimate goal of invertebrate risk assessment. Without healthy populations, some crucial ecosystem services (e.g. pollination or pest control) provided by such Non-Target Arthropods (NTAs) can no longer be sustained. To help identify potential blind spots in the current risk assessment, we analysed how different landscape compositions influence pesticide effects using a landscape model. We used the Animal Landscape and Man Simulation System (ALMaSS) from Topping et al. (2003) to model two predatory species, the spider Erigone atra and beetle Bembidion lampros, in four different European landscapes. Modelled agricultural landscapes were chosen to represent different levels of natural habitats and crop diversity. Pesticide application was modelled based on the properties of a real pesticide applied on one focal crop (oilseed rape) for 10 years. Effects on (sub-)population sizes and recovery times back to the control scenario were tracked. We found significant effects on sub-populations in non-crop areas already for permitted pesticide application rates. This shows action-at-a-distance effects of the pesticide in the simulation and thus a potential risk to populations not explicitly considered in ERA. For the four different landscapes we modelled, we could identify differences in effect strengths on species population sizes for the same pesticide amounts. Effect strengths appear to be influenced most by the proportion of the sprayed focal crop in the landscape and the proportion and composition (many small or few big patches) of natural habitats. While current landscape and species models can already provide new insights in landscape level effects, we see limitations that prevent the immediate use in regulatory risk assessment. To be able to use landscape models to support risk assessment decisions in the future, models need to be further developed and tailored to ERA needs.

Disclaimer/Disclosure: This work was funded by the European Food Safety Authority (EFSA) as part of the AENEAS project (OC/EFSA/ED/2021/02).

4.05.P-Mo323 Modelling the Accumulated External Pesticide Load of NTAs– Spatial and Trait-Specific Patterns for In-Field and Specific Off-Field Scenarios
*Heike Fremdt[1], Sonja Braaker[2], Carola Schriever[3], Pernille Thorbek[4], Andrew C. Chapple[1] and **Thomas G. Preuss**[1], (1)Bayer AG, Germany, (2)BASF S.A.S, France, (3)BASF SE, Germany, (4)Apd/EE, BASF plc, United Kingdom*
Recently, the revision of the Guidance Document on Terrestrial Ecotoxicology on plant protection products (i.e., non-target arthropods (NTA), non-target terrestrial plants (NTTP) and in-soil organisms) has been mandated to EFSA. For all organisms, the risk assessment consists of both the exposure and the effect assessment in several tiers. The Ecotoxicologically Relevant Exposure Quantity (EREQ) links an effect tier to an exposure tier. It is the exposure quantity that best correlates to an ecotoxicological effect. For NTAs, the current EREQ is basically the deposition rate on the surface of interest (plant canopy or soil). Based on current guidance the EREQ is calculated for the in-field and the off-field and is based on the application rate, the multiple application factor, and - for the off-field - the vegetation distribution factor and a drift factor. As a revised EREQ, the pesticide mass reaching an individual arthropod or the pesticide mass in and on the individual arthropod has been suggested. Additionally, at a spatial scale, a further distinction between the off-field, the off-crop in-field and the in-crop has been proposed. For the

revised EREQ, additional information about (i) the distribution of the applied product in an area as well as (ii) the movement patterns of a species plus body characteristics of that species need to be considered. A small-scale movement model for four theoretical NTA-species types, calculating the accumulated external pesticide load by individuals of a population in a defined exposure period, was developed recently by Becher et al. The distribution of the accumulated external pesticide load per individual differed significantly for model settings for the distribution pattern and the species-type defined by a particular trait combination. So far, the model by Becher et al. was run using assumed pesticide distribution patterns for some theoretical off-field only. In the present work additional pesticide distribution patterns as expected for the in-field have been established as well as specific off-field scenarios. The accumulated external pesticide load for the four NTA-species types used by Becher et al. have been determined and depend on the exposure pattern as well as their movement traits. The results provide valuable information on the identification of EREQs for all spatial scales for different NTA species trait types and demonstrate that it will be not simple to define a realistic worst-case.

4.05.P-Mo324 Hoverfly Decline in the Context of Landscape Intensification

Michael Thomas Marx[1], *Jochen Zubrod*[2], *Michael E. Greve*[1], *Thorsten Schad*[1], *Christian Baden*[1] *and Christian Maus*[1], *(1)Bayer AG, Germany, (2)Zubrod Environmental Data Science, Germany*

Insect decline is influenced by various causal factors acting at different spatial and temporal scales and affecting different insect groups. Hoverflies are amongst the best studied insect taxa regarding behaviour, ecology, habitat and resource needs of adults and larvae. Hoverflies could therefore serve as surrogate group for many other insect taxa. The strongest decline trends occurred mainly in ubiquitous and widely distributed taxa not specialised to a low number of floral food sources. These species appear in high abundances if the habitat and resource needs are suitable. More specialised species with normally lower abundances are lower affected by the observed decline trend. From an ecological viewpoint this observation is remarkable, as specialised species with narrow habitat and resource needs are normally affected stronger by disturbances. The landscape analysis showed a possible explanation for this observation. From 1989 to 2014 especially the grasslands were converted to an intensified management. Extensive grassland habitats are an important habitat for many hoverfly species offering a wide variety of flowers as food source for adults. The intensification of the grassland habitats lowers down the ability of sufficiently high numbers of flower species subsequently dropping down the abundance of unspecialised hoverfly species. More specialised species can use the existing flower resources better resulting in weaker decline tendencies. There are no differences in the decline trends of resident and migratory species indicating that possible causes for the decline are also occurring within the investigated habitat. Further, the hoverfly community showed a clear dominance shift between 1989 and 2014. In 1989 the dominant species preferred open land/grassland and forest edge/shrubland habitats whereas in 2014 only species preferring forest edge/shrubland habitats were dominant. This shift also underlines that grassland intensification is a relevant factor for the hoverfly decline in this investigation site.
For larvae the disappearance of pastures and extensive grasslands can be considered as important decline causes. Especially for species with rat tailed larvae highly dependent on cattle manure the decline trend was considerably high.

4.06 Bioremediation and Phytoremediation for Recovering Ecosystems from Legacy and Emerging Contaminants

4.06.T-01 Bacterial Pore Sealing as a Tool for Chemical Risk Reduction

José Luis García[1], *Damian Serrano*[2], *Frederic Coulon*[3], *Carmen Fernandez-Lopez*[2] *and Jose Julio Ortega-Calvo*[1], *(1)Instituto de Recursos Naturales y Agrobiología de Sevilla (IRNAS-CSIC), Spain, (2)Centro Universitario de la Defensa, Universidad Politecnica de Cartagena, Spain, (3)School of Water, Energy and Environment, Cranfield University, United Kingdom*

Immobilisation of organic pollutants is currently regarded as an effective strategy to mitigate chemical risks in soil by significantly reducing their bioavailability. In this study we explored the sealing potential of *Bacillus subtilis* DSM10, a bacterium well known for its biofilm formation ability and chemotactic response with biochar to reduce the aqueous diffusion of naphthalene. We also further investigated the possibility of enhancing immobilization by retarding chemical diffusion through micrometer-size pores clogged by bacterial biofilms. This was achieved using gamma-aminobutiric acid (GABA), a strong chemoattractant. These combined approaches aimed to provide a robust method for limiting pollutant mobility in soil systems. To study the effect of biochar and microbial biomass on naphthalene diffusion without physical restrictions, biochar and *B. subtilis*, alone or in combination, were dispensed directly over 14C-naphthalene crystals inside conical glass tubes provided with a naphathalene trap filled with a 200 mM cyclodextrin solution. The second approach included the use of bioreactors. The lower reservoir was filled with a buffer containing 14C-naphthalene crystals and 10 mM of GABA. In the upper reservoir 1 ml of *B. subtilis* biomass or buffer without GABA was dispensed. Lower and upper reservoir were separated by a 3 µm pore size membrane. Also, there was a naphthalene trap filled with cyclodextrins attached to the upper reservoir. In all cases, the flow of naphthalene was determined by quantifying radioactivity in the cyclodextrin solutions. With the first approach, both biochar and *B. subtilis* significantly reduced diffusion- biochar alone by approximately 50% while *B. subtilis* alone by 87%, after 8 days. In the second set-up, the concentrated bacterial solution applied on top of the membrane decreased the flow of naphthalene through the membrane to less than 50% after 8 days. In this case the effect seemed to be enhanced by the chemoattraction exerted by GABA, resulting in the clogging of the pores. This work uniquely combines biochar and *B. subtilis* to immobilise naphthalene, highlighting the synergistic effects of bacterial biofilm formation and chemotaxis in reducing pollutant diffusion. The use of GABA as a chemoattractant to enhance bacterial activity and pore clogging offers a novel mechanism to limit contaminant mobility in soil and water systems.

4.06.T-02 From NatCom to Syncom. Optimisation of Hydrocarbon-Degrading Communities and Their Use in Contaminated Soils

*Laura Carrera-Ruiz[1], David Duran-Wendt[1], Monica Montoya[2], Blanca Juez-Sanchez[3], Marta Martin[1], Rafael Rivilla[1] and **Miguel Redondo-Nieto**[1], (1)Departamento de Biología, Universidad Autonoma de Madrid, Spain, (2)Universidad Politecnica de Madrid, Spain, (3)Acciona Construccion R&D Centre Madrid, Spain*

Bioremediation using bioaugmentation accelerates pollutant degradation by introducing microbial communities, yet natural consortia (NatCom) may include environmentally or medically undesirable strains. This study aimed to construct a synthetic microbial community (SynCom) from a NatCom isolated from hydrocarbon (TPH) contaminated soil in Noblejas, Spain. Manual and automated culturomics techniques using diesel as sole carbon source were carried out to isolate several candidate strains that were further characterized by 16S rDNA V3-V4 amplicon sequencing and whole genome sequencing, looking for their hydrocarbon-degrading potential. Thus, we formulated a SynCom composed of five strains taxonomically assigned as *Pseudomonas putida*, *Delftia acidovorans*, *Novosphingobium* sp., Achromobacter *aegrifaciens*, and *Rhodococcus jialingiae*. Additionally, *Rhodococcus* sp. WAY2, previously characterized for diesel degradation, was included to enhance metabolic pathways. SynCom stability was validated through successive culture passages in a minimal medium with diesel as the sole carbon source.

Field-scale experiments were performed using 20 tons of hydrocarbon polluted soils divided in two biopiles over a time span of 360 days. The first biopile did not receive any treatment and the second was biostimulated with vermicompost and bioaugmentated with the SynCom culture. As expected, in the non-inoculated biopiles there was little change in diversity (determined as Bray Curtis distances) once the system was stabilised (after 90 days). On the other hand, in the treated biopile there were changes in the communities that were stable from day 240 after inoculation. These changes in microbial composition correlated with the decrease in TPH concentration. Thus, while in the control biopile a decrease of contaminants up to 58% of the original concentration was detected at 360 days, in the treated biopiles an average reduction of 63% was reached at 90 days, which was reduced to 29% at day 240, where it remained stable at around 24% at day 360. The main changes were observed primarily in the abundance of long-chain aliphatic hydrocarbons (>C21-C35) and polycyclic hydrocarbons with between 21 and 35 carbons.

Metagenomics and culturomics allow the construction of effective and safe SynComs to be used as inoculants in bioremediation technologies requiring bioaugmentation. We have constucted and tested one of these SynComs and proved its efficiency at field scale.

Disclaimer/Disclosure: This work was funded by the GREENER project of the European Union's Horizon 2020 research and innovation program (Grant Agreement No. 826312) and by Agencia Estatal de Investigación, Ministerio de Ciencia e Innovación (TED2021-130996B-I00).

4.06.T-03 Contaminated Soil Bioremediation by Indigenous Hydrocarbon-Degrading Bacteria

***Sara Accardo*[1]*, Simona Schiavo*[2]*, Laura Caiazzo*[2]*, Massimo Pezza*[2]*, Juri Rimauro*[2]*, Patrizia Paganin*[2]*, Flavia Tasso*[2]*, Chiara Alisi*[2] *and Sonia Manzo*[2]*, (1)ENEA CR, Italy, (2)ENEA - Italian National Agency for New Technologies, Energy and Sustainable Economic Development, Italy*

Bioaugmentation has significant advantages for remediating soil contaminated with total petroleum hydrocarbons (TPH). This technique utilizes specific microbial populations, including biosurfactant-producing strains, to enhance the degradation of hydrophobic hydrocarbons by improving their solubility, mobility, and bioavailability. The aim of this work was to determine the effectiveness of a microbial formulation in soil bioremediation by evaluating the biodegradability of pollutants and the attenuation of toxic effects with an approach that includes chemical, microbiological, respirometric and ecotoxicological evaluation. Fifty bacterial strains from the ENEA-MIRRI Microbial Collection were screened for biosurfactant production using Oil Spreading and E24 assays. The best biosurfactant producers, such as *Pseudomonas glycinis* A2-5 and *Rhodococcus qingshengi* OSS19, were tested for compatibility and used to formulate a microbial consortium. Bioaugmentation tests were conducted in biometer flasks using a consortium of nine hydrocarbon-degrading indigenous bacteria at an inoculum of 10610^6 106 CFU/ml. Experimental parameters were optimized by monitoring CO2 evolution, TPH degradation, and ecotoxicity over 90 days. Chemical analyses via GC-MS revealed almost complete degradation of alkanes and alkenes and a 64 78% reduction in hopanes. The microbial load increased during the first 30 days before stabilizing, confirming the bioaugmentation process's efficiency. Ecotoxicological assays demonstrated a general reduction in soil toxicity over time. However, toxicity peaked at T15 in bioaugmented samples, particularly for *Chlorella vulgaris*, which remained highly sensitive throughout the experiment, possibly due to secondary metabolite formation. By T90, toxicity levels for *Daphnia magna* and plant species decreased significantly, indicating soil recovery. This study highlights the potential of bioaugmentation combined with biosurfactant-producing strains for remediating petroleum-contaminated soils. Future work will incorporate *Pseudomonas glycinis* A2-5 biosurfactant into the microbial formula to further enhance bioremediation efficiency. Ecotoxicological tests using multiple species proved effective in assessing soil health and recovery.

4.06.T-04 A Virtuous Cycle of Phytoremediation, Pyrolysis and Biochar Towards Safe PFAS Levels in Soil and Food

***Hans Peter H. Arp*[1]*, Nathalie Briels*[2]*, Thomas D. Bucheli*[3]*, Nicolas Estoppey*[4]*, Andrea Gredelj*[4]*, Nikolas Hagemann*[5]*, Sylvain Lerch*[5]*, Simon Lotz*[6]*, Daniel Rasse*[7]*, Hans Peter Schmidt*[6]*, Erlend Sormo*[4] *and Gerard Cornelissen*[8]*, (1)NGI/NTNU, Norway, (2)ARCHE Consulting, Ghent (Wondelgem), Belgium, (3)Environmental Analytics, Agroscope, Switzerland, (4)NGI, Norway, (5)Agroscope, Switzerland, (6)Ithaka Institute, Switzerland, (7)NIBIO, Norway, (8)NGI/NMBU, Norway*

Remediation of PFAS-impacted agricultural soil with destructive methods (soil washing, excavation, incineration, chemical oxidation) is challenging because of the diffuse character of the pollution. Furthermore, these destructive approaches will impair soil ecosystem services and cause carbon emissions. In-situ methods such as phytoremediation and sorbent amendment are less intrusive, more cost-effective, and align with the concept of nature-based solutions. Biochar from biomass combustion in the absence of air (pyrolysis), has been proposed as a sustainable sorbent material, due to its benefits in terms of carbon sequestration, nutrient recycling / waste handling, energy generation and contaminant immobilization. This is particularly the case if the biochar is made from contaminated biosolids, as pyrolysis can mineralize the PFAS. Pyrolyzing the contaminated biomass additionally alleviates the constraints of biomass disposal. Amendment with 1% sludge biochar or (activated) high-temperature (> 800 °C) wood biochar reduced PFOS leaching from contaminated soil by up to 92-99%, with notably better effectiveness for long-, than for short-chain (C4 and C5) PFAS (40-70%).

A high potential for terrestrial and aquatic plant bioaccumulation of PFAS has been shown for ultra-short chain and short-chain perfluoroalkyl acids (PFAA). Most studies were performed with crop species (e.g. corn, wheat, rapeseed) and rarely tested in field conditions. The main challenges for phytoremediation include not only high variabilities between the plant uptake potential of different PFAS (chain length, charge), but also high variations between plant species and field conditions, making it hard to predict removal efficiencies. With the suggested solution, we create a virtuous cycle when combining phytoremediation to accumulate short-chain PFAS in plant biomass, destroying of accumulated PFAS by pyrolytic treatment, and applying the resulting biochar to immobilize long-chain PFAS in agricultural top-soils.

4.06.T-05 Bioremediation Strategies for Polychlorinated Biphenyl-Contaminated Marine Sediments: Advancing Methods for Sustainable Toxicity Reduction

***Miray Kurtoğlu**[1] and Hale Demirtepe[2], (1)Izmir Institute of Technology, Graduate School of Science and Engineering, Department of Biotechnology and Bioengineering, Turkiye, (2)Izmir Institute of Technology, Faculty of Engineering, Department of Environmental Engineering, Turkiye*

Polychlorinated biphenyls (PCBs) are persistent organic pollutants that pose significant environmental challenges due to their resistance to natural degradation, bioaccumulative nature, and potential toxicity to ecosystems and human health. Found extensively in marine sediments, especially near industrialized coastal areas, PCBs persist for decades, requiring sustainable remediation solutions. Traditional remediation techniques, such as dredging or chemical treatment, are costly, disruptive, and impractical for large-scale applications. Bioremediation as a sustainable alternative offers the potential to take advantage of microbial activity to degrade PCBs with minimal ecological impact. This study evaluated the bioremediation strategies, including bioaugmentation, biostimulation, and natural attenuation, to identify methods that effectively transform highly chlorinated and toxic PCBs into less harmful forms. The research employed microcosm experiments using sediments collected from highly contaminated sites. The bioaugmentation set mimicked the application of enriched microbial consortia, including species known for reductive dechlorination, to accelerate the breakdown of PCBs. A biostimulation set was operated to enhance the indigenous microbial activity through nutrient amendments, while a natural attenuation set was used to understand the sediment's natural ability to degrade PCBs. Microcosms were incubated under anaerobic conditions for six months, with samples collected at four-week intervals to monitor PCB degradation. GC-MS was used to measure changes in PCB concentrations and detect potential degradation products. Preliminary findings indicated that biostimulation led to sharp changes, including a significant reduction in higher chlorinated PCB homologs, while bioaugmentation exhibited slower but consistent decreases in higher chlorinated congeners and increases in lower chlorinated ones. Compared to the natural attenuation set, biostimulation showed faster changes, and bioaugmentation demonstrated steadier but sustained transformation over time. This study highlighted the potential of bioremediation strategies for PCB-contaminated marine sediments, contributing to the development of practical and sustainable remediation solutions.

Disclaimer/Disclosure: This study was funded by the Scientific and Technological Research Council of Turkey (TÜBİTAK) under project number 122Y005.

4.06.P Bioremediation and Phytoremediation for Recovering Ecosystems From Legacy and Emerging Contaminants

4.06.P-Mo326 Organic Amendments and Forest Restoration as a Nature Based Solution for Recovering a Construction Site Area with Spoil Material Treated with Lime

***Anna Barra Caracciolo**[1], Rodolfo Gentili[2], Antonio Finizio[2], Ludovica Rolando[1], Alessandra Narciso[1], Chiara De Carolis[1], Livia Mariani[1] and Paola Grenni[1], (1)Water Research Institute-National Research Council, Italy, (2)University of Milano Bicocca, Italy*

Tunnel industry can cause habitat loss and degradation due to soil consumption and vegetation cover removal. Huge quantities of excavated material (Spoil Material, SM) are currently being produced for several large engineering and infrastructural project implementation. In line with circular economy objectives, SM can be used as a by-product if it meets specific EU guidelines (Waste Framework Dir. 2008/98/EC) and national legal requirements. Lime addition is often necessary to stabilize and move SM to its final destination site, in accordance with practical construction site procedures. However, lime-treatment strongly increases SM pH, making it unsuitable for filling areas designed for greening projects. This work reports a case study from a highway construction site, between Florence and Bologna (Bellosguardo, Italy), where a nature-based solution (NBS) was applied for decreasing the high basic pH of the SM and restoring the work site with a forest vegetation similar to the surrounding area. The greening project consisted in the use of organic amendments mixed to the SM (the bottom substrate), a 50 cm top layer of soil (surface soil previously removed from the construction area) and the planting of different endemic species (mixed oak wood). In order to test the effectiveness of the restoration project

considering the site-specific conditions, 27 mesocosms (15m2; 1.25 m depth), were setup. Three zero-km organic amendments (digestate; compost; de-oiled olive pomace) were applied. Two control conditions (only top soil, and no-treated SM) were also performed. The tree establishment, soil natural microbial community abundance and activity and soil pH and organic carbon were assessed at different depths (0-30 cm, top soil; 35-50 soil-SM intermediate layer, mixed with amendments; 50-60 SM) and times (12, 24 and 36 months). Adding amendments to SM (at 1 y), the pH values significantly decreased (from 12 to 10.7), thanks to the introduction of active microbial populations, organic C and N, if compared with controls. At 36 months, pH values (9) were close to those of the surface soil (pH 8). Total tree mortality was 15% and mostly affected oaks (*Quercus pubescens*, 38%). Tree performances among treatments did not show statistical differences even if one species (*Olea eurpaea*) grown in surface soil had the best performance. These results were useful for the real green restoration at the construction site, which is currently in progress.

4.06.P-Mo327 Compost Effectiveness in Improving Soil Quality and Plant Growth in an Agricultural Soil Contaminated by Antibiotics and Copper

*Chiara De Carolis[1], Lisa Ciadamidaro[2], Michel Chalot[2], Alessandra Narciso[1], Ludovica Rolando[1], Paola Grenni[1], Tristan Couraud[2] and **Anna Barra Caracciolo**[1], (1)Water Research Institute, National Research Council (IRSA-CNR), Italy, (2)Chrono-environnement UMR 6249, Universite de Franche-Comte CNRS, France*

The use of organic amendments as fertilizers and copper as a fungicide in agricultural farming can be a source of emerging contaminants, such as antibiotics (ABs) and heavy metals. Consequently, agroecosystems can be an environmental reservoir for ABs and Cu, and their accumulation in plants and eventual transfer through food chains to animals and humans necessitate further investigations. The co-presence of ABs and Cu can adversely affect plants and their associated microbiome. To find solutions for improving soil quality and capacity to respond to contamination is a research priority.

The aim of the present work was to evaluate the effectiveness of a vegetable-derived compost (1%) in counteracting the negative effects of an antibiotic mixture (sulfamethoxazole, chlortetracycline and ciprofloxacin, 7 mg/kg each) and copper ($CuSO_4$ 30 mg/Kg) on the growth and development of lettuce plants (*Lactuca sativa*, var. Crispa). Moreover, soil and rhizosphere microbial communities were evaluated in terms of abundance (DAPI counts), structure (NGS) and enzymatic activities (dehydrogenase, phosphatase, ?-glucosidase). Additionally, the possible presence of antibiotic resistance genes (ARGs) was also evaluated. Plant growth and physiology were assessed measuring biomass, number of leaves, leaf area, root elongation and chlorophyll content.

In compost presence, microbial abundance and activities increased, some microbial taxa were favoured (e.g., Gammaproteobacteria and Alphaproteobacteria) and others declined (e.g., Actinobacteria). In accordance with microbiological data, compost also promoted the highest plant biomass, leaf number and area, root elongation and chlorophyll content. Overall, the co-presence of copper and ABs increased the relative abundance of the sul1 and sul2 genes in soil, however, this phenomenon was significantly lower in plant presence.

4.06.P-Mo328 Plant-Assisted Bioremediation and Bioaugmentation Treatments for Recovering Multi-Contaminated Soils

***Cristina Cavone**[1], Gino Naclerio[2], Antonio Bucci[2], Anna Barra Caracciolo[1], Aurora Rutigliano[3], Pietro Cotugno[4], Ludovica Rolando[1], Ilaria Savino[1], Paola Grenni[1], Vito Felice Uricchio[3] and Valeria Ancona[3], (1)Water Research Institute, Italian National Research Council, Italy, (2)Dept. of Biosciences and Territory, University of Molise, Italy, (3)Construction Technology Institute, Italian National Research Council, Italy, (4)Dept. of Chemistry, University of Bari, Italy*

Inorganic pollutants and persistent organic pollutants (POPs) represent a considerable threat for environment and human health in both terrestrial and aquatic ecosystems. The green technologies, including Plant-Assisted Bioremediation (PABR) and Bioaugmentation, have the potential to be effective and sustainable tools for recovery and remediation of contaminated soils. This work reports a laboratory-scale case study, which was conducted for evaluating the efficacy of these technologies and design experimental protocols. The soil was collected from a historically contaminated area in southern Italy, exhibiting varying levels of polychlorinated biphenyls (PCBs) and heavy metals (HMs) (with average concentrations exceeding legal limits for urban areas for both organic and inorganic pollutants).

The microcosm experiments were conducted for 90 days in plant pots, considering four different treatments: (1) a negative control (only historically contaminated soil), (2) PABR with the *L. angustifolia* medicinal plant, previously demonstrated to thrive in HMs-contaminated soils, (3) bioaugmentation with a microbial consortium, comprising four hydrocarbon-oxidising bacterial strains belonging to the Acinetobacter, Rhodococcus and Gordonia genera, and (4) a combination of the microbial consortium with the plant species. The experiment was conducted at a temperature of 22°C, with a photoperiod of 8/16-night/day and a relative humidity of 80/65%-night/day.
At the start and the end (90d), analyses of soil properties (pH, EC), quantification of contaminants (PCBs and heavy metals), microbial abundance, dehydrogenase activity and 16S rDNA gene Next Generation Sequencing were performed.
The preliminary results suggest that the combined use of plants and microorganisms promoted microbial abundance and improved contaminant degradation at 90 days.
The analysis of microbial structure revealed that lavender and the bacterial consortium stimulated the proliferation of specific microbial populations such as Xanthobacteraceae, Geobacteriaceae, and Bacillaceae.
This study supports the effectiveness of microorganisms and plant interactions in increasing soil quality and promotes contaminant removal.

4.06.P-Mo329 Assessment of Microplastic Effects on Plant Assisted Bioremediation Strategy for Recovering Contaminated Soils

*Ilaria Savino[1], Claudia Campanale[2], Paola Grenni[1], Cristina Cavone[1], Francesca Garganese[3], Anna Barra Caracciolo[1], Vito Felice Uricchio[4] and **Valeria Ancona**[4], (1)Water Research Institute, Italian National Research Council, Italy, (2)Italian National Institute of Health, Department of Environment and Health, Italy, (3)Dipartimento di Scienze del Suolo, della Pianta e degli Alimenti, University of Bari Aldo Moro, Italy, (4)Construction Technology Institute, Italian National Research Council, Italy*

Plant-assisted bioremediation (PABR) is a sustainable technology that exploits natural interactions between plant roots and rhizosphere microorganisms for degrading, immobilizing or extracting contaminants from contaminated soils. This approach is particularly effective in removing from soil a wide range of pollutants such as heavy metals, polycyclic aromatic hydrocarbons, pesticides, PCBs and dioxins. Recently, micro- (MPs) and nanoplastics (NPs) have emerged as new contaminants, posing major environmental challenges and serious concerns for soil biota health. MPs and NPs from intensive agronomic practices (e.g. mulching sheeting, organic fertilisers such as biosolids) and use of reclaimed water can have both a direct physical impact on soil structure and biota (e.g. microorganisms and plants) and act as carriers of hazardous chemicals. On the one hand, new experimental approaches are evaluating the use of plant technologies as a means of removing micro and nanoplastic from soil. On the other hand, few studies have evaluated the effects of microplastics on the efficiency of strategies such as PABR in multi-contaminated soils. Microplastics can alter soil physical and chemical parameters, as well as plant physiology and microbial diversity in rizosphere. Alteration in soil pH can affect mobility and bioavailability of pollutants such as heavy metals and nutrients, and indirectly hinder plant growth and bioremediation processes. For example, root exudates, which have an important role for stimulating microbial communities in PABR, can be metabolically modulated and reprogrammed by presence of microplastics, affecting plant-microbiome synergic interactions. In this context, this work aims to review and discuss effects of microplastics on soil key abiotic and biotic factors (pH, electrical conductivity, organic carbon and soil nutrients, organic and inorganic pollutants, plant growth, microbial and fungal communities, radical exudates, soil amendments) which regulate PABR technology for recovering contaminated soils

4.06.P-Mo330 Collaborative Approaches to Water Management: Bridging the Global North and South

***Pedro N. Carvalho**, Department of Environmental Science, Aarhus University, Denmark*

Water scarcity and access to safe drinking water and sanitation remain critical global challenges. By 2040, it is projected that one in four children will live in regions of extreme water stress due to over-exploitation, population growth and climate change. The Global South is particularly vulnerable to these problems. To address the clean water crisis, a circular and inclusive approach to water resources management is essential. Expertise from European Union countries can address research needs and knowledge gaps in the Global South, while evaluating current challenges and best practices in the Global North.

The NEUTRAL4GS project brings together six academic institutions, one SME and one water utility to develop and test nature-inspired solutions for urban water management through co-creation and co-design strategies between partners from the Global South and the EU. The project focuses on different types of urban water, including stormwater, greywater and wastewater, and integrates a range of treatment technologies. The project aims to develop innovative engineering solutions and processes, including membranes, biomass carriers and bioremediation precursors, to improve water quality and meet specific challenging performance targets, such as the removal of micropollutants and heavy metals. Laboratory-scale test units of individual and/or combined technologies will be implemented to assess their feasibility. This presentation will focus on bioremediation approaches and technologies for wastewater treatment. Nature-based solutions (NBS) will be applied at the laboratory scale for controlled process studies focusing on priming microbial communities for enhanced micropollutants treatment. Microbiological interventions will be employed to enhance remediation processes, including the biodegradation of microplastics. This project task will collaborate closely with others to integrate optimized processes into NBS handling stormwater and greywater, where relevant.
Holistic sustainability and economic assessments will guide the development and prioritization of these technologies. NEUTRAL4GS aims to pioneer innovative water treatment solutions, ensure social acceptance and adoption of these technologies, and generate significant societal, environmental, and public health benefits. By raising awareness and involving local authorities and communities, NEUTRAL4GS strives to ensure the sustainability and long-term success of its outcomes beyond the project's lifetime.

Disclaimer/Disclosure: This project has received funding from the European Union's Horizon Marie *Skłodowska*-Curie Actions (MSCA) under grant agreement 101182652. Views and opinions expressed are, however, those of the author(s) only and do not necessarily reflect those of the European Union or European Research Executive Agency. Neither the European Union nor the granting authority can be held responsible for them.

4.06.P-Mo331 Potential of Bivalves for Bioremediation of Wastewater – Comparative Assessment of Biofiltration and Biosorption

*Fatima Jesus[1], Erica Pascoal[1], Erika Sousa[1], Goncalo Abreu[1], Diogo Mantas[1], Leandro Monteiro[1], Mariana Sousa[1], Vania Calisto[1] and **Joana Luisa Pereira**[2], (1)University of Aveiro, Portugal, (2)Department of Biology, University of Aveiro, Portugal*

Wastewater treatment plants are generally ineffective at removing some contaminants of emerging concern from wastewater, which represents a threat to the environment and human health. Several approaches have been developed to overcome this problem, bioremediation being a promising one. The bivalve *Corbicula fluminea* has advantageous attributes as a wastewater bioremediation agent considering its high tolerance and status as an invasive species outside its native range in Asia. Hence, this study aims to evaluate the potential of *C. fluminea*, considering both the living organisms (biofiltration) and the shells (biosorption), in the removal of some of the most frequent contaminants from urban wastewater, namely caffeine (CAF), carbamazepine (CBZ), diclofenac (DIC), fluoxetine (FXT), ibuprofen (IBU), metformin (MET), naproxen (NPX), paracetamol (PCT) and sulfamethoxazole (SMX), further appraising their ecotoxicological effects in the microalgae *Raphidocelis subcapitata*. Biofiltration efficiency was evaluated using 10 bivalves per 0.5 L during 48 h. Adsorption to milled shells was assessed under similar conditions (50 g shell/L). Posteriorly, adsorption was tested under fixed conditions: pretreated (pyrolyzed and acid-washed) shells, at higher dose (100 g shell/L), at pH 7.0. All tests started with contaminants at 0.5 mg/L. Biofiltration showed low efficiency, with removal percentages below 40%, except for FXT (93%) and PCT (59%). In contrast, milled shells removed mainly CAF (62%) and FXT (42%), with removal percentages below 40% for the remaining contaminants. Clams were more efficient in removing CBZ, DIC, MET, FXT and PCT whereas the opposite was observed for CAF and NPX. Biosorption by pretreated shells showed a removal efficiency higher than 50% only for DIC (80%), FXT (67%) and MET (53%). Toxicity of the FXT sample to the microalgae decreased after biofiltration but increased for most of the remaining samples. Unexpectedly, toxicity of CAF and FXT samples did not decrease after biosorption to milled shells, suggesting that toxicity cannot be explained based only on compounds removal. Overall, results suggest that living bivalves would not likely represent a viable solution for urban wastewater treatment. Biosorption using pretreated shells was successful and should be further explored in adsorption tests with real wastewater to fully assess the potential of this approach for urban wastewater treatment.

Disclaimer/Disclosure: CESAM by FCT/MCTES (UIDP/50017/2020 + UIDB/50017/2020 + LA/P/0094/2020) through national funds; Project NYMPHE, funded by the European Union (Grant 101060625; DOI: 10.3030/101060625).

4.06.P-Mo332 Sorption of Road Runoff Pollutants to Wood-Derived Biochars
Xiangyu Ji[1], *Anett Georgi*[2], *Katrin Mackenzie*[2], *Hauke Harms*[1] *and Lukas Wick*[1], *(1)Helmholtz Centre for Environmental Research (UFZ), Department of Applied Microbial Ecology, Germany, (2)Helmholtz Centre for Environmental Research (UFZ), Department of Technical Biogeochemistry, Germany*
Blue-green infrastructures, such as tree trench biofilters, have untapped potential to reduce pollutants in road runoff. Runoff is characterized by highly variable quantities and chemical loads that may overwhelm microbial transformation and lead to pollutant transfer to the subsurface. Augmenting biofilter systems with carbon-based sorbents may allow for fast transitory retention of pollutants in high load periods and continuous slow release for long-term biodegradation. Wood-based biochar thereby emerges as a sustainable and cost-effective sorbent. However, the role of physicochemical biochar properties in efficient transitory retention and slow pollutant release for subsequent biodegradation is still poorly studied. Here, we present the sorption equilibria and kinetics of four typical road runoff pollutants (naphthalene, methyl tert-butyl ether, 1,3-diphenylguanidine, and perfluorooctanoic acid) of untreated biochar (BC) and activated biochar (BAC) in batch experiments. Isotherm data for adsorption and desorption were well fitted by the Freundlich model. BAC exhibited a significantly higher adsorption performance, e.g. the equilibrium loading for 1,3-diphenylguanidine at an environmentally relevant concentration of 30 µg L-1 in the aqueous phase is about 100-fold higher than that of BC. All model pollutants showed strong desorption hysteresis in both BC and BAC, with even greater hysteresis observed in BC. Sorption kinetics data were evaluated using the film-surface diffusion model to estimate surface diffusion coefficients for pollutants transport inside biochar particles. These parameters, together with Freundlich isotherm parameters, were applied to three different transport models to predict breakthrough curves under varying water flow rates and pollutant inflow concentrations. Based on the model results, suitable experimental conditions were selected to conduct column experiments. Experimental data were then used to validate the models and improve their accuracy to predict real-world scenarios. Our results indicated that BAC had a superior adsorption capacity and kinetics, and a lower desorption hysteresis compared to BC. The significance of predictions from batch tests combined with modelling tools for different scenarios in biochar-amended biofilters was discussed. These will form the basis for the assessment and control of microbe sorbent interactions for efficient bioavailability and biodegradation of runoff pollutants in tree trench biofilters.

4.06.P-Mo333 Industrial Hemp (*Cannabis sativa*) as a Dual-Purpose Solution for Soil Remediation and Bioenergy Production in Sewage Sludge-Amended Soils
Inesa Kniuipyte[1], *Marius Praspaliauskas*[1] *and Jurate Zaltauskaite*[2], *(1)Laboratory of Heat Equipment Research and Testing, Lithuanian Energy Institute, Lithuania, (2)Department of Environmental Sciences, Vytautas Magnus University, Lithuania*
Sewage sludge (SS) reuse in agriculture is encouraged due to its nutrient-rich composition; however its high heavy metal content, potential environmental risks, and limited guidelines for safe application pose significant problems. Contaminants accumulating in SS-treated soils can harm soil organisms, reduce soil fertility, endanger food crop yields and enter the food chain, contaminate surrounding areas. Furthermore, excessive sludge application can result in long-term soil pollution, leading to the need to clean up amended sites. The use of energy crops in soils treated with SS is a sustainable dual-purpose method for soil remediation that combines it with bioenergy production.
The aim of this study was to assess the potential of energy crop industrial hemp (*Cannabis sativa* L.) for soil remediation and bioenergy production in soils amended with sewage sludge (SS) and sewage sludge char (SSCh) at application rates of 25 200 Mg/ha. SS and SSCh application highly affected Cr, Cu, Ni and Zn concentrations in soil (ANOVA, $F_{SS} > 21.80$, $F_{SSCh} = 35.20$, $p < 0.001$) and led to increased metal concentrations ($p < 0.05$). Soil amended with 25-100 Mg/ha SS and 25 Mg/ha SSCh had moderate heavy metal contamination. Application of 200 Mg/ha SS and 50-200 Mg/ha SSCh caused significant pollution. Our findings show that the application of SSCh resulted in more polymetallic soil contamination than the soil amended with the same SS dose. Heavy metal concentrations in soil were significantly reduced after industrial hemp cultivation, with higher removal efficiencies at moderate sludge application rates (25 50

Mg/ha). The heavy metals removal efficiency could be ranked Zn > Cu > Cr > Ni. Only marginal removal was detected for Ba, Fe, Na, Ti and Al. These reductions underscore industrial hemp s effectiveness in mitigating heavy metal posed environmental risks.
The optimal fertilization with SS or SSCh could be up to 25 Mg/ha, when the highest efficiency of contaminant removal from the soil and the highest plant biomass production and bioenergy production were observed. Higher application rates increased the risk of heavy metal contamination, emphasizing the importance of optimized sludge usage. The study highlights the dual benefits of industrial hemp cultivation in mitigating soil pollution and contributing to renewable energy sources, offering a sustainable strategy for managing sewage sludge and its environmental impacts.

4.06.P-Mo334 How Persistent are Persistent Organic Pollutants in Soil? Exploring Bioavailability
Jose Julio Ortega-Calvo[1], *Rosa Posada*[1], *Carmen Fernandez-Lopez*[2] *and José Luis García*[1], *(1)Institute of Natural Resources and Agrobiology of Seville - Spanish National Research Council (IRNAS-CSIC), Spain, (2)Polytechnic University of Cartagena, Spain*
Nature-based solutions (NBS), such as bioremediation and phytoremediation, offer promising avenues for soil restoration. Traditional NBS approaches focused solely on total pollutant removals have proven unpredictable and often fall short of legislative remediation goals. This is particularly true with persistent organic pollutants (POPs) such as PAHs. With a focus on bioremediation, this overview presentation will explore the paradigm shift towards addressing bioavailability of POPs, surpassing mere total pollutant removals, to reach acceptable risk reductions. To achieve this, two questions must be addressed: (1) How to influence bioavailability processes related to the biodegradation of PAHs? and (2) How can this knowledge be used to sustainably reduce chemical risks in soil? In relation to the first question, considering that contaminants that are not bioavailable to degrading microorganisms can be bioavailable to humans and ecological targets, it is necessary to bring forward microbial activity to acceptable levels of risk reductions. Our nature-based engineering components were demonstrated to enhance biodegradation and reduce environmental risks, mainly channelled through the water phase, at various levels of bioavailability processes, encompassing interactions between contaminants and soil, their transportation, and biological processing. The specific focus in our research was to unveil low-risk strategies such as the controlled increase in bioavailability to microorganisms targeting slow-desorption pollutant fractions with (bio)surfactants, fine-tuning the deposition and motility of microbial degraders, co-mobilizing non-motile inoculants, and effectively capturing pollutants through plant/biochar arrangements, showcasing their potential to transform soil remediation practices. In relation to the second question, operating on bioavailability requires the use of standardized methods that can systematically be used in bioremediation to measure bioavailable fractions, evaluating more realistically operations and end-points, in addition to assessments based on total concentrations only. Desorption extraction (Tenax) is especially useful in bioremediation and constitutes the basis for an ISO standard on soil quality. Our group has already used this approach in the evaluation of bioavailability-oriented bioremediation, proposing application paths in the context of sustainable recovery of soils affected by military activity.

4.06.P-Mo335 Influence of a Natural Nonionic Surfactant on Biodegradation of Slowly Desorbing PAHs in Contaminated Soil
Rosa Posada, *Alicia Fernandez-Vazquez and Jose Julio Ortega-Calvo, Instituto de Recursos Naturales y Agrobiología de Sevilla (IRNAS-CSIC), Spain*
In many cases, the residual pollutant concentrations after bioremediation suppose unacceptable risks, especially for hydrophobic organic compounds such as PAHs. The half-lives of these compounds are very high if are present as slowly desorbing forms, and may remain in the contaminated soils after bioremediation, still causing potential toxicity. The design of strategies to enhance the biodegradation of the slowly desorbing compounds is therefore needed in the bioremediation field. The use of biosurfactant agents, such as rhamnolipid, have been suggested as the environmentally friendly technology for the remediation of soils contaminated with hydrophobic organic compound. Plant-produced surfactants, such as *Quillaja saponin*, constitute a realistic alternative to microbial surfactants, as related to costs. Our objectives were: to characterize the initial desorption kinetics of native PAHs present in this contaminated soil to determine the extent of slowly desorbing fractions, to use 14C-PAHs radiorespirometry determinations as a physiological indicator of biodegradation, to study the effect of the saponin on the biodegradation and bioavailability of these compounds and to propose mechanisms to improve the action of this biosurfactant on slowly desorbing PAHs in contaminated soils. The soil used was a heavily

creosote polluted soil with a PAHs total concentration of 4075 mg/kg. Saponin, a non-ionic biosurfactant, was added at concentration of 7 mg/g (w/w). The desorption kinetics, which was determined by Tenax extraction, was a necessary tool in the optimization of saponin role in bioremediation of PAHs. Saponin was added at 56 days, when the remaining PAHs were present in a slowly desorbing form as a result of the biodegradation of fast desorbing PAHs by the native microbial population of the soil. The biodegradation percentages of total PAHs (sum of 16 EPA PAHs) achieved were 59 % and 90 % for the natural attenuation and bioestimulation-saponin treatments, respectively. Thus, the data obtained by adjusting the desorption kinetics successfully predicted the right time for biosurfactant application during bioremediation. The results obtained show that an appropriate integration of the natural surfactant into bioremediation of PAHs contaminated soils, promoting biodegradation of the slow desorption fractions, improve the bioremediation performance and have lower costs and environmental impacts.

4.06.P-Mo336 Improving Remediation of Military-Contaminated Soil by Natural-Based Solutions

Carmen Fernandez-Lopez[1]*, Maria Balseiro-Romero*[2]*, Pol Martin*[3]*, Alicia Fernandez-Vazquez*[4]*, José Luis García*[4]*, Joaquim Vila*[3]*, Jose Carlos Castilla-Alcantara*[4]*, Rosa Posada*[4]*, Magdalena Grifoll*[3] *and Jose Julio Ortega-Calvo*[4]*, (1)Centro Universitario de la Defensa-Universidad Politecnica de Cartagena (CUD-UPCT), Spain, (2)IRNAS-CSIC, Spain, (3)Universidad de Barcelona, Spain, (4)Instituto de Recursos Naturales y Agrobiología de Sevilla (IRNAS-CSIC), Spain*

Bioremediation is a main natural-based solution for the clean-up of polluted soils. Pollutant biodegradation is improved by stimulating the activity of the autochthonous microorganisms through the improvement of soil conditions (biostimulation) and/or through the addition of allochthonous microorganisms with specific metabolic traits (bioaugmentation). In heterogeneously polluted soils with organic xenobiotics, it is essential to guarantee the dispersal of the inoculants over the volume of soil and to promote the bioavailability of the pollutants, which will in turn enhance bioremediation efficiencies. Organic pollutants introduced into the soil by military activities include energetics, chemical warfare agents and other military chemical compounds, generally grouped as potentially toxic compounds (PTC). Contamination by PTC on military bases is mainly caused by spillage of chemicals in storage areas (fuels, oils, lubricants, paints, solvents and corrosives). Their concentrations in the soil of military areas can be unacceptably high and, together with their high toxicity and persistence, can give rise to environmental hazards. The main objective of this study was to design a natural-based strategy for a soil contaminated with kerosene from a military air base (southern Spain), based on the combination of biostimulation and bioaugmentation in the presence of a model plant (sunflower, *Helianthus annuus*) and at the greenhouse scale (pots with 2 kg of soil). The bioaugmentation inoculant was a mixture of a motile strain (*Pseudomonas putida* G7), which is chemotactic towards sunflower root exudates, and a biosurfactant producing strain (*Bacillus subtilis* DSM10). This inoculant was designed to enhance the dispersion of the biosurfactant producer strain all over the soil volume in pots by chemotaxis-mediated co-mobilisation together with a mobile strain of *P. putida* G7. Microbial community response to treatments were assessed by 16S rRNA metabarcoding and qPCR targeting total (16S rRNA gene) and hydrocarbon-degrading (toluene dioxygenase gene, TOD) bacterial communities. The degradation of kerosene was favored in the presence of the plants. Biostimulation had a major effect on soil microbial community, clearly stimulating native aromatic hydrocarbon degrading populations (TOD). Bioaugmentation resulted in effective soil colonization by strain DSM10, that caused slight changes in microbial community structure between treatments.

4.06.P-Mo337 Metagenomic and Metatranscriptomic Analyses of a Bacterial Consortium for the Bioremediation of Total Petroleum Hydrocarbons Polluted Soil

Emiliana Pandolfo[1]*, David Duran-Wendt*[1]*, Ruben Martinez-Cuesta*[2]*, Monica Montoya*[3]*, Laura Carrera-Ruiz*[2]*, David Vazquez-Arias*[2]*, Daniel Garrido-Sanz*[4]*, Miguel Redondo-Nieto*[2]*, Sandra Curiel-Alegre*[5]*, Rocio Barros*[6]*, Marta Martin*[2] *and* ***Rafael Rivilla***[2]*, (1)Universidad Autonoma de Madrid, Spain, (2)UAM, Spain, (3)UPM, Spain, (4)University Lausanne, Switzerland, (5)Universidad de Burgos, Spain, (6)Universidad De Burgos, Spain*

In order to design a bioremediation inoculant, a bacterial consortium was generated from a soil with a long story of hydrocarbon pollution in Noblejas (Toledo, Spain) by enrichment cultivation. Serial cultures of hydrocarbons polluted soil samples were grown in a minimal medium using diesel (1 mL/L) as the sole carbon and energy source. The bacterial composition of the Noblejas Consortium (NC) was determined by 16S rRNA gene amplicon libraries sequencing. The consortium contained around 50 amplicon sequence variants (ASVs), and the major populations belonged to the genera Pseudomonas, Enterobacter, Delftia, Stenotrophomonas, Achromobacter, Acinetobacter, Novosphingobium, Allorhizobium-Neorhizobium-Rhizobium, Ochrobactrum and Luteibacter. All other genera were below 1%. Metagenomic analysis of

NC has shown a high abundance of genes encoding enzymes implicated in aliphatic and (poly) aromatic hydrocarbons degradation, and almost all the pathways for hydrocarbon degradation were represented. Metagenomic analysis allowed the construction of high quality metagenome assembled genomes (MAGs) for the major players of NC. Metatranscriptomic analysis has shown that several of the ASVs are implicated in hydrocarbon degradation, being Pseudomonas, Acinetobacter and Delftia the most active populations. This consortium has been successfully used at microcosm (200 g) and pilot (700 kg) scales for Total Petroleum Hydrocarbons (TPHs) biodegradation. On the pilot scale, the combined use of the consortium plus biostimulation with vermicompost achieved 90.3% TPH removal after 90 days. The introduction of the consortium had a large impact on the polluted soil bacterial community, reflected by a decrease in alpha-diversity. Beta diversity analysis also showed that the bacterial community was different in the treated soil as compared with a control, untreated soil.

4.06.P-Mo338 Shotgun Metagenomic Analysis of Microbial Community Profiles and Functions in Petroleum Hydrocarbon-Polluted Soils

Chioma Blaise Chikere[1] and ***Chidinma Peace Okafor****[2], (1)Department of Microbiology, University of Port Harcourt, Port Harcourt, Nigeria, (2)IMO State University, Nigeria*

This study investigated the effects of petroleum hydrocarbon pollution on impacted soils of the Niger Delta. Petroleum pollution of the soil negatively impacts the microbial population, biodiversity, and activities within the area. The resistance of the indigenous microbial population to the toxicity of hydrocarbons is based on their energetic strategies and metabolic versatility in using the pollutant as carbon and energy source. In this study, shotgun metagenomics was used to analyze microbial diversity. Metabolic capability and functional profile of two petroleum hydrocarbon polluted sites in Bodo (N4.620134,7.282998E) and Tombia (N04o47.714, E0006o51) communities, both in Rivers State Nigeria were investigated. Predominant phyla across all samples are the Proteobacteria. Other oleophilic phyla previously reported in oligotrophic environments like Acidiplilum, Actinobacteria, Verrucomicrobia, and Acidobacteria were found in the polluted soil. Stress response genes (cold shock, heat shock, starvation, osmotic stress, pH and oxidant detoxification) were well expressed in all samples analyzed. Genes for DNA repairs and de novo biosynthesis were also well expressed in addition to hydrocarbon degradation hydrogenases. Functional pathways include those for fermentation, respiration, de novo biosynthesis, and element cycling. These findings provide insight into the microbial activities and functional capabilities of indigenous microflora in petroleum hydrocarbon polluted soil.

4.06.P-Mo339 Assessing the Impact of Metals on Ecotoxicological Responses, Biomarkers, and Bioaccumulation in *Ceratophyllum demersum*: Implications for Phytoremediation Strategies

Santiago Martinez, Maria Elena Saenz, Jose Alberdi and ***Walter D. Di Marzio****, PRIET DCB UNLU CONICET, Argentina*

Phytoremediation processes for removing metals present in liquid effluents generally involve continuous exposure to relatively stable concentrations of these elements. These processes can be classified as tertiary treatments for effluents of industrial and municipal origin.

The removal of metals using aquatic plants is well-studied, although there are not many studies that employ the species *Ceratophyllum demersum* under conditions of continuous exposure from the discharge of a liquid effluent.

In this work, we define the sensitivity of this species to common metals found in discharges resulting from anthropogenic activities.

Acute ecotoxicity parameters, exposure biomarkers, and bioaccumulation kinetics are characterized based on exposure to solutions of each individual metal.

The results provide tools for monitoring the level of biochemical stress in the plants during the removal process, their tolerance to threshold concentrations, equilibrium times for reaching maximum accumulable concentrations (SST and MAC), and bioconcentration factors for each metal (BCF).

MAC (mg metal/g dry weight), steady state time (SST) to reach MAC in days and BFC for Ni, Zn and Cd were SST 14.14, 0.88, 4.24; MAC 0.87, 1.69, 0.15 and BCF 146, 210, 311.

The data obtained will contribute to the design of phytoreactors to be used for the removal of the studied metals and the biomonitoring of the plant fitness during remediation process.

4.06.P-Mo340 A Phytoremediation Mesocosm Using Aquatic Macrophyte Species at Different Plant Densities: First Results

Maria Elena Saenz[1], Ricardo Santiago Martinez[1], ***Walter Dario Di Marzio[1]****, Jose Luis Alberdi[1], Gabriel Dario Di Marzio[2], Hernan De la Vega[3], Mariano Pistorio[4] and Andres Toscani[5], (1)PRIET - Depto Cs Bs UNLu CONICET, Argentina, (2)PRIET - UNLu, Argentina, (3)Div Matematica, Depto Cs Bs UNLu, Argentina, (4)IBBM- CONICET Fac. Cs Exactas UNLP, Argentina, (5)IBBM-CONICET Fac Cs Exactas UNLP, Argentina*

Release of heavy metals into the environment due to different activities are sources of metal contamination. Phytoremediation is a biobased technology, fundamental in the context of circular economy and sustainability.
The aim of this study was to develop a multispecies and multimetal mesocosm at lab scale, for the removing of heavy metals from a wastewater that discharge into Luján river (Bs Aires). The aquatic macrophytes chosen were *Lemna gibba*, *Ceratophyllum demersum* and *Elodea callitrochoides*. Plants were sampled from local streams and maintained in extensive cultures. The metals chosen were Cd, Zn and Ni as they are the most frequent in Luján river. Three different densities were assay (7, 15 and 30 grs/L of each specie). Different parameters were analyzed to determine which provided more efficient phytoremediation: removal rate, bioaccumulation factor, activities of antioxidant enzymes and whole ecotoxicity. Ecotoxicological assessments were done with *P. subcapitata* growth inhibition test and *D. magna* acute toxicity test. The experiments were set up for 10 days. Samples of multimetal solution were taken at time intervals. At the end of the experiments, an aliquot of plants was dried and digested for metal determination, while a subsample of fresh material was used to enzyme activities determinations. The density chosen was 15 grs/L as the selected criteria were better and the whole ecotoxicity of the phytoremediated solution was lower (Initial multi-metal ecotoxicity: *P. subcapitata* EC50-96hs: 1.3%; *D. magna* EC50-48hs: 6.4%; final phytoremediated solution ecotoxicity: *P. subcapitata* EC50-96hs: 57%; D. magna EC50-48hs: non ecotoxic). The experimental set up was repeated at this density but an inoculation with a microbial consortium from a wastewater bioreactor treatment plant was added to the system, as a strategy to enhance phytoremediation. Metagenomic analysis of this consortium was done by 16S rRNA sequencing analysis of V3-V4 region. A wastewater with metals that discharge to Luján river was treated under these two simultaneous conditions, resulting in a whole ecotoxicity removal and improvement of water quality parameters. The multispecies at selected density mesocosm in conjunction with inoculate with a microbial consortium demonstrated to be an excellent strategy to enhance metal removal.

4.06.P-Mo341 LIFE PFASTER (PFAS Systemic Regional Approach to Assess Spatial Distribution, Transfer, Exposure and Remediation of WideSpread Pollution in Willebroek, Flanders)

John van Tol[1], Lies Teunen[2]*, Maarten de Jonge[3] and Froukje Kuijk[4], (1)Soil & Groundwater, TAUW bv, Netherlands, (2)Flemish Research Institute for Nature and Forest (INBO), Belgium, (3)Flemish Environment Agency (VMM), Belgium, (4)Public Waste Agency of Flanders (OVAM), Belgium*

Extensive persistence of PFAS and its toxicity to life on earth, bioaccumulation, and adverse health and ecological effects make PFAS a top priority pollutant. Contemporary one substance, one assessment approaches to remediate PFAS are difficult to apply through the different compartments given the extensive group of precursors and metabolites that can arise in the environment. Current knowledge is insufficient to understand the risks posed by diffuse pollution to both people and the environment (one health approach) and has not yet been translated and integrated into management nor remediation practices. The recently started LIFE PFASTER (PFAS systemic regional approach to Assess Spatial distribution, Transfer, Exposure and Remediation of wide-spread pollution in Willebroek, Flanders) research project, aims to improve soil and water quality by developing a regional systemic remediation approach to reduce diffuse pollution with PFAS of soil, sediment, water and biota, including innovative, cost efficient methods to assess the spatial distribution and identification of exposure routes of the contaminants and the design and piloting of a replicable remediation approach beneficial for biodiversity and human health. Key steps (work packages in the project) include: 1) Assess composition, spatial distribution, transfer and ecological and related health risks of PFAS; 2) Design and pilot innovative and replicable (nature-based) remediation techniques, including phyto- and mycoremediation, mycofiltration, constructed and floating wetlands, in-situ flushing and physical-chemical groundwater treatment (including treatment trains with nanofiltration); 3) Develop a remediation approach and 4) Replicate the remediation approach and best practice techniques at other sites in Flanders and Europe.

Project area is a former industrial site (paper factory) located in Willebroek, Flanders (Belgium) and its surroundings, including a nature conservation area, an exemplary case for a heavily PFAS contaminated site and surrounding area. The project started in October 2024 and will run for 5 years. The 11 LIFE PFASTER expert partner organisations have a vast network of local, regional, (inter)national partners for project input, dissemination and replication. See for more info: https://ovam.vlaanderen.be/nl/w/naar-een-gebiedsgerichte-en-natuurgebaseerde-aanpak-van-pfas-verontreiniging-in-vlaanderen-met-de-steun-van-europa?redirect=%2Fnieuws and soon www.lifepfaster.eu

4.06.P-Mo342 Remediation of PFAS Contaminated Soil using the Novel Combination of Biochar Sorbent Stabilization and Phytoaccumulation: First Insights

Ingrid Rijk[1]*, Sigrun Dahlin*[2]*, Anja Enell*[3]*, Alf Ekblad*[4]*, Maria Florberger*[5]*, Felicia Fredriksson*[1]*, Susanne Karlsson*[6]*, Dan Berggren Kleja*[7]*, Katinka Krahn*[8]*, Anna Karrman*[1]*, Maria Larsson*[1]*, Christina Prevazi*[1]*, Viktor Sjoberg*[1]*, Erlend Sormo*[9] *and Matilda Wiberg*[10]*, (1)Orebro University, Sweden, (2)Department of Soil and Environment, Swedish University of Agricultural Sciences (SLU), Sweden, (3)Swedish Geotechnical Institute, Sweden, (4)School of Science and Technology, Orebro University, Sweden, (5)Geosyntec Consultants AB, Sweden, (6)Structor Miljo ost AB, Sweden, (7)Swedish University of Agricultural Sciences / Swedish Geotechnical Institute, Sweden, (8)Lindum, Norway, (9)Norwegian Geotechnical Institute (NGI), Norway, (10)Structor Miljoteknik AB, Sweden*

Biochar is a carbonous, porous material produced by pyrolysis of biomass, which can be potentially used as a sorbent for contaminants and nutrients in soil and water. In recent years, biochar has increasingly been put forward as an amendment that can be used for soil remediation, whereby contaminants are stabilized and ecological restoration of soil is promoted. This could especially be a solution for larger areas with low- to medium level contaminated soil outside source zones. As a positive side effect, addition of biochar could also enhance the carbon content and soil quality of degraded soils.

Two potential effective (bio)char types for remediation of soils contaminated with per- and polyfluoroalkyl substances (PFAS) are activated carbon (AC) and sewage sludge-based biochar (BC-SS). Both have demonstrated similar, large sorption capabilities for longer chain PFAS, however, sorption of shorter chain PFAS may be less effective. Furthermore, the profound effects that these sorbents can have on soil organisms also remain an area requiring further research.

A potential solution may be a combined approach of sorbent stabilization with phytoaccumulation, where shorter chain, more mobile PFAS may be taken up by plants for subsequent removal and destruction. In this study, this novel in situ remediation concept combining sorbent stabilization and phytoaccumulation is tested. Additionally, the toxicological and ecological effects on soil organisms are also assessed, complementing the PFAS sorption and mobility study.

We added 2% of either a wood-based, commercially available AC or a SS-BC to PFAS contaminated sandy loam soil, together with 1% compost and inorganic fertilizer. These mixtures were tested for PFAS leaching, uptake in perennial ryegrass and earthworms, and effects on the grass, earthworms and the soil microbiological activity and community composition. This presentation will present the first insights on comparing the effectiveness of the two biochar types in this combined sorbent-phytoaccumulation approach, as well as compare the effects and uptake between different soil biota. This information is of vital importance, as the potential usage of biochar-remediated low-to medium contaminated areas is most likely urban parks where not only the contaminant stabilization, but also the ecological soil quality has to be taken into account.

Disclaimer/Disclosure: This research was funded by the Knowledge Foundation, Sweden (KKS).

4.06.P-Mo343 What Biochar Properties Determine Sorption Strength of Perfluorooctanoic Acid (PFOA) to 23 Biochars Produced from Various Organic Waste Types?

Karen Ane Skjennum[1]*, Katinka Krahn*[2]*, Erlend Sormo*[3]*, Raoul Wolf*[4]*, Aleksandar I. Goranov*[5]*, Patrick Hatcher*[5]*, Thomas Hartnik*[6]*,* ***Hans Peter H. Arp***[7]*, Andrew R. Zimmerman*[8]*, Yaxin Zhang*[9] *and Gerard Cornelissen*[3]*, (1)Lindum AS, Norwegian University of Life Sciences (NMBU), Norway, (2)Lindum AS, Norway, (3)Norwegian Geotechnical Institute (NGI), Norwegian University of Life Sciences (NMBU), Norway, (4)Norwegian Geotechnical Institute (NGI), Norway, (5)Old Dominion University, United States, (6)Norwegian Institute of Bioeconomy Research (NIBIO), Norway, (7)Norwegian Geotechnical Institute (NGI), Norwegian University of Science and Technology (NTNU), Norway, (8)University of Florida, United States, (9)Hunan University, China (Mainland)*

Biochar has the potential to be a sustainable sorbent for per- and polyfluoroalkyl substances (PFAS). However, what biochar properties influence PFAS sorption are still poorly understood. Here, we produced twenty-three biochars from sewage sludge, food waste reject, wood wastes, and one reference substrate (wood pellets), at various temperatures (500-800 °C) using two pyrolysis technologies. The purpose of this study was to fill the knowledge gaps on and develop a better understanding of which waste-derived biochar properties most strongly influence PFAS sorption. The biochars were characterized for pore volume, surface area, elemental content, ash content, pH, zeta potential, condensed aromatic carbon (ConAC) and their -OH functional group content. Sorption isotherms of perfluorinated octanoic acid (PFOA) was determined by the Polanyi-Dubinin-Manes (PDM) and Freundlich models, and the sludge-based biochars outperformed the wood-derived biochars. Multiple linear regression models were developed to couple a selection of biochar properties to sorption of PFOA. The capacity (V0), and affinity terms (E) from the PDM model, and the capacity (nF) and affinity (log KF) terms from the Freundlich model were chosen as response variables.
A high porosity in pores with diameters (3 6 nm), about twice the molecular dimensions of PFOA, was identified as the key factor governing sorption capacity. The greater sorption capacity of PFOA to the sludge biochars was attributed to their mesoporous structure, whereas the wood biochars predominately consisted of micropores being inaccessible for PFOA due to steric hindrance. Sorption affinity was likely governed by hydrophobic interactions between PFOA and aromatic carbon-rich regions, especially for the wood biochars. Our results show that various organic waste can serve as feedstock for production of biochar for soil and water treatment. The insights gained in this study can improve the understanding of which parameters that are most important for PFAS sorption and thereby guide pyrolysis conditions and selection of feedstocks towards production of high-quality biochars with physicochemical properties tailored to its intended application.

Disclaimer/Disclosure: This work was funded by the Research Council of Norway (grant numbers 299070: VOW Valorization of Organic Waste, 302371: SLUDGEFFECT Life cycle effects from removing hazardous substances in sludge and plastic through thermal treatment, 305498: Use of waste-based sorbents and active materials in ex-situ and in-situ treatment of polluted soil), Lindum AS and Scanship AS.

4.06.P-Mo344 Potentially Toxic Elements Distribution and In Vitro Bioaccessibility at House Fire Impacted Sites on Gitxsan Territory (Hazelton), British Columbia, Canada
***Matt Dodd**[1], Anissa Watson[2] and Leila Darwish[2], (1)School of Environment and Sustainability, Royal Roads University, Canada, (2)Skeena Watershed Conservation Coalition, Canada*
Potentially toxic elements (PTEs) may be present in soil after a house fire. The human health and ecological risk associated with the PTEs may be elevated and as such soil remediation may be required to restore the site for rebuilding. The Skeena Watershed Conservation Coalition (SWCC), a non-profit environmental organization located in Hazelton, BC on the unceded and traditional territories of the Gitxsan First Nations, is exploring the development of regenerative and community-based ecological solutions that support community resilience and a healthy watershed for future generations in a culturally appropriate manner. Recent structural fires have burned down houses in the Gitxsan communities of Gitwangak, Gitanmaax and Sik-E-Dakh. These sites pose a contamination threat to the community, as well as serve as a continual reminder of trauma. In partnership with the Gitxsan First Nation communities, SWCC is investigating bioremediation as a potential remedial option for these house fire impacted areas. Characterization of the contaminants present at these sites is an essential first step. This study was initiated with a workshop in each of the First Nation communities to engage members in the planning, sampling, conducting remediation and follow up monitoring. Potential contaminants of concern arising from house fires were also discussed. After completion of the workshop, First Nations participants assisted in collecting 74 soil samples from five house fire impacted sites. The samples were analyzed for PTEs by x-ray fluorescence. PTEs including arsenic, chromium, copper, lead and zinc in some of the samples exceeded Canadian Environmental Soil Quality Guidelines for residential land use. Ongoing work includes determining soil pH, in vitro bioaccessibility and the potential human health risk associated with exposure to the PTEs using Health Canada guidelines incorporating receptor characteristics for Canadian First Nation Populations. Recommendations on limiting exposure to contaminated soils at each of the house fire sites will be developed. Remedial options analysis will be conducted in collaboration with SWCC and the Gitxsan community members to determine the most suitable remedial technique. If the communities are interested in further remedial action, it is possible that the sites could become the focal

points of action for future community-based hands-on bioremediation application and learning opportunities that incorporate indigenous knowledge systems.

4.07.A Advancing Treatment of Organic Micropollutants in Water and Wastewater

4.07.A.T-01 Integrated Assessment of Biological Activated Carbon Filters with UV/Peracetic Acid Pretreatment for Mitigating Organic Micropollutants and Toxicity in Treated Wastewater

Sana Ajaz[1]*, Frederic Leusch*[1]*, Mikaela Radke*[1]*, Ruby Michael*[2]*, Prasad Kaparaju*[2] *and Ashraf Aly Hassan*[3]*, (1)Australian Rivers Institute, School of Environment and Science, Griffith University, Australia, (2)School of Engineering and Built Environment, Nathan Campus, Griffith University, Australia, (3)Department of Civil and Environmental Engineering, College of Engineering, United Arab Emirates University, United Arab Emirates*

The presence of organic micropollutants (OMPs) in wastewater poses a significant environmental concern, affecting humans and aquatic ecosystems even at trace levels. With increasing population and climate-driven water shortages, wastewater reuse strategies are gaining importance. This study evaluated the efficacy of biological activated carbon (BAC) filtration in combination with UV/peracetic acid (UV/PAA) pretreatment for OMP removal and toxicity reduction in treated wastewater. UV/PAA pretreatment was compared to UV/H?O?, assessing the removal efficiency of key OMPs and overall water toxicity via chemical analysis and bioassays for estrogenicity, cytotoxicity, phytotoxicity, and oxidative stress. The results indicated that UV/PAA pretreatment was more effective than UV/H2O2 in degrading a wide range of OMPs, including trimethoprim (44.5%), venlafaxine (42.5%), diuron (52%) and diclofenac (100%). UV/PAA also significantly reduced photosynthesis inhibition (53%) compared to UV/H2O2 (21%). Biofiltration following UV/PAA reduced algal toxicity by 63% and lowered the estrogenic load by over 60%, bringing estrogenicity risk from high to moderate. While both treatments reduced bacterial toxicity caused by advanced oxidation processes, biofilters treated with UV/H2O2 pretreated water showed a greater reduction (25%) than those with UV/PAA pretreatment (3%). Microbial community analysis revealed that biofilters supported the growth of OMP-degrading bacteria such as Pseudomonas, Mycobacterium, and Rhodococcus. UV/PAA pretreatment facilitated the growth of species such as Acinetobacter and Anaerolinea that have the capability of degrading estrogens and other OMPs, indicating its effectiveness in mitigating toxicity. This study provides valuable information on the synergistic combination of UV/PAA oxidation with biofiltration, in degrading OMPs and mitigating toxicity in treated wastewater.

4.07.A.T-02 Micropollutant Mass Balance in an Integrated System Coupled by Biological Treatment and Nanofiltration with Recirculation

Claudia Rodriguez Gonzalez[1]*, Gabriel Sigmund*[2]*, Dainis Sudmalis*[2] *and Huub H.M. Rijnaarts*[2]*, (1)Netherlands, (2)Wageningen University & Research, Netherlands*

Conventional wastewater treatment plants (WWTP) are not designed to completely remove organic micropollutants (OMPs), due to the low concentration in influent wastewater, limited contact time within the system (from 8-12 h) and some OMPs being persistent to biodegradation. Nanofiltration (NF) may be used to retain OMPs from treated effluents. NF is suitable to remove OMPs from 200-2000 Da, it has a lower consumption of energy compared to reverse osmosis and classical ozonation, and it does not generate unwanted byproducts, except a concentrate stream.

Here we explore the combination of conventional wastewater treatment with NF to enhance the overall OMP removal. Recirculating the concentrate stream (retentate) from the NF system into the biological treatment might increase the concentration and contact time of OMPs within the biological system and hence reduce their mass flux in the treated effluent.

We have observed that the concentrate stream from the NF system can be treated in the biological system. Negatively charged compounds and larger molecules are being retained and upconcentrated in the bioreactor. The mass flux of irbesartan, sulfamethoxazole and bezafibrate in the effluent was decreased by 3.9, 5.1 and 4.7 times following NF re-circulation. Salts from the concentrate in terms of sulphates and phosphates did not affect the microbial activity of the sludge in the integrated system. Thus, a concentration of 90% NF recovery is feasible in a continuous integrated system. Our work unravels mass fluxes of OMPs withing real water matrices and a novel integrated system that couples SBR and NF to decrease the release of OMPs from WWTP effluents in the environment. This work can inform the planning and implementation of future integrated WWTP setups to comply with the new European urban wastewater treatment directive.

4.07.A.T-03 Removal of Organic Micropollutants Under Dry and Wet Weather in a Full-Scale Aerobic Granular Sludge Plant

Zhaolu Feng[1], *Heike Schmitt*[2], *Mark van Loosdrecht*[2] *and Nora B. Sutton*[1], *(1)Environmental Technology, Wageningen University & Research (WUR), Netherlands, (2)Department of Biotechnology, Delft University of Technology, Netherlands*

Aerobic granular sludge (AGS) is an effective wastewater treatment widely applied worldwide for the removal of nutrients and organic matter. However, limited information is available on the effectiveness of full-scale AGS plants for removing organic micropollutants (OMP), particularly during wet weather. This study investigated the occurrence and removal of OMPs, including 19 pharmaceuticals and 2 industrial compounds, in a full-scale AGS plant during both dry and wet weather over one year.

We selected a full-scale AGS plant located in Utrecht, the Netherlands as the targeted AGS plant, and collected monthly 24-hour composite water samples and grab sludge samples from May 2023 to April 2024. 21 OMPs were extracted from water and sludge samples and measured by LC/MS. Concentrations of ammonia and organic matter (both particulate and soluble) were measured with HACH Lange GMBH kits.

The results show that Influent concentrations of 5 pharmaceuticals and 1 industrial compound exceeded 1 ?g L-1, which were diluted by rainfall. Influent loadings of 7 OMPs (absolute OMP amount in ?g day-1) were significantly increased during wet weather, likely from sewage sediment resuspension and urban runoff. Average removal efficiencies of 11 compounds achieved greater than 20%, with 5 of them exceeding 50%, in the AGS plants. Simple linear regression results between OMP removal efficiencies and flow rates showed that biodegradable OMPs were more strongly affected by increased influent volumes (as indicated by steeper slopes) than OMPs primarily removed through sorption. Additionally, correlation analysis results showed that the removal of soluble organic matter was significantly correlated (p-value < 0.05) with the removal of 14 OMPs, suggesting that organic matter removal may be an indicator for OMP removal in the AGS plant. After AGS treatment, 8 compounds in the effluent remained above their predicted no-effect concentration levels, indicating potential ecological and human health risks in the receiving water. During wet weather, effluent OMP loadings increased mainly driven by reduced removal efficiency. Additionally, compared to activated sludge plants, the AGS plant exhibited comparable or slightly higher OMP removal efficiency during dry weather.

Overall, this study is the first to investigate OMP removal during wet weather in a full-scale AGS plant and propose the potential impact of increased flow rates on biodegradable OMPs or OMPs mainly removed through sorption.

4.07.A.T-04 Integrating Foam Fractionation into the Activated Sludge Process for Per- and Polyfluoroalkyl Substances Removal from Landfill Leachate: An Energy-Efficient Approach

Sanne Julie Smith[1], ***Josephine van Ruiten***[1], *Merle de Kreuk*[1] *and Kay Schmidt*[2], *(1)Delft University of Technology (TU Delft), Netherlands, (2)Royal Haskoning DHV, Netherlands*

Per- and polyfluoroalkyl substances (PFAS) are synthetic chemicals known for their persistence, bioaccumulation, and toxicity. Landfill leachate is a major source of PFAS contamination in the environment. However, conventional wastewater treatment plants (WWTPs) are not designed to effectively remove PFAS, highlighting the need for specialized treatment technologies. Foam fractionation (FF) has shown promise in removing PFAS from landfill leachate, achieving removal efficiencies up to 60%. FF is considered a sustainable method, as it does not require chemical reagents or adsorbents. However, energy for aeration impacts its cost and energy efficiency.

This study investigates integrating FF into the activated sludge (AS) process, offering a more energy- and cost-efficient approach to mitigate PFAS emissions. AS processes already rely on aeration to treat nutrients and organic matter, and foam formation frequently occurs due to the presence of surfactants and filamentous bacteria. While foam formation is typically suppressed to avoid operational challenges, this study investigates its potential use for PFAS removal.

Laboratory experiments were conducted using a bench-scale activated sludge reactor treating landfill leachate. In the first phase, foam formation was suppressed with an antifoam agent to mimic conventional operations. This ensured that PFAS removal could occur solely through sorption to sludge. In the second phase, no antifoam was added, allowing natural foam formation and its subsequent removal. The analysis involved the general chemistry and the concentrations of 32 different types of targeted PFAS, in the

influent, effluent, and foam. The PFAS analyses were performed using Solid Phase Extraction (SPE) followed by LC-MS/MS.
Results indicated negligible PFAS removal during the first phase, while the second phase achieved removal efficiencies comparable to standalone foam fractionation. However, also solids were enriched in the foam, potentially impacting the microbial population in the bulk solution. Preliminary observations suggest no significant difference in biological performance between the two phases. These findings offer promising insights for WWTP operators seeking cost-effective strategies to mitigate PFAS emissions. Given the widespread use of activated sludge reactors in municipal and industrial wastewater treatment plants, integrating foam fractionation into these processes presents a potential scalable solution.

4.07.A.T-05 Chemical and Toxicological Evaluation of Advanced Oxidation Treated Pharmaceutical Residues in Wastewater
Martien Graumans[1]*, Wilfred F.L.M. Hoeben*[2]*, Frans G.M. Russel*[3] *and Paul T.J. Scheepers*[1]*,*
(1)Department of Environmental Science, Radboud Institute for Biological and Environmental Science (RIBES), Radboud University, Netherlands, (2)Department of Electrical Engineering, Electrical Energy Systems Group, Eindhoven University of Technology, Netherlands, (3)Division of Pharmacology and Toxicology, Department of Pharmacy, Radboud University Medical Center, Netherlands
Pharmaceuticals are commonly used to prevent and treat diseases or alleviate pain in human and veterinary healthcare. Drugs are primarily discharged via domestic and hospital sewage water (HSW) for removal by wastewater treatment plants (WWTPs). WWTPs are not designed for the removal of these complex chemicals, leading to release into the aquatic environment and negatively impacting biodiversity. To complement WWTPs and prevent incomplete removal of unwanted pharmaceuticals, on-site wastewater treatment can contribute to mitigation for this problem. This study aimed to assess the effectiveness of on-site oxidative treatment of hospital sewage water (HSW) using advanced oxidation processes (AOPs). Thermal plasma and UV-C/H_2O_2 oxidation technology were applied on surrogate matrices spiked with 14 drugs (iopamidol, iomeprol, diatrizoic acid, fluoxetine, diclofenac, metoprolol, cyclophosphamide, carbamazepine, terbutaline, phenazone, acetaminophen, ciprofloxacin, doxycycline and metformin). In addition, untreated end-of-pipe HSW was analysed and subjected to oxidation. All drugs were partly or completely decomposed by thermal plasma and UV-C/H_2O_2 treatment. In HSW, 10 pharmaceuticals were quantified ranging in concentrations from 0.08 to 2400 µg/L. When AOP was applied, it was found that overall pharmaceutical degradation in HSW was nearly equivalent to results found in surrogate matrices. Subsequently the effectiveness and safety of AOP treatment was evaluated using a HeLa cytotoxicity assay and in silico environmental risk assessment. Acute cytotoxicity of untreated HSW was reduced after oxidation. Quantitative structure-activity relationship modelling (QSAR) of aquatic toxicity demonstrated good concordance with the cytotoxicity findings. We have shown that AOPs can be considered promising technologies to remove medicinal residues from hospital wastewater.

4.07.B Advancing Treatment of Organic Micropollutants in Water and Wastewater

4.07.B.T-01 Which Factors Limit the Adsorption of Per- and Polyfluoroalkyl Substances (PFAS) on Activated Carbon During Drinking Water Treatment?
Marko Pranic*, Wageningen University, Netherlands*
Per- and polyfluoroalkyl substances (PFAS) are persistent micropollutants commonly detected in surface and groundwater at low ng/L concentrations. The current EU directive limits PFAS in drinking water to 100 ng/L for a mixture of PFAS compounds of concern, with a proposed reduction to 4.4 ng/L. Although activated carbon adsorption is widely used for PFAS removal, rapid breakthrough in activated carbon filters limits effectiveness, requiring frequent regeneration and raising treatment costs. Most studies on PFAS adsorption have been conducted at higher concentrations, making it challenging to predict performance under environmentally relevant conditions.
This study aims to identify factors limiting PFAS adsorption on AC in drinking water treatment, focusing on low ng/L concentrations. We tested a mixture of short- and long-chain PFAS compounds on widely used activated carbons with different pore size distributions. Batch (isotherm and kinetic) and rapid small-scale column tests were conducted under varying PFAS concentrations, temperatures, and organic matter fractions. For the mentioned conditions we report experimentally obtained surface diffusion coefficients and isotherm data which we use to predict PFAS breakthrough.

Results show that data from higher PFAS concentrations significantly overpredicts adsorption at ng/L levels which is likely a consequence of multilayer PFAS adsorption at high concentrations. Temperature increases from 10 to 30 °C decreases short-chain PFAS adsorption by several times. whereas long-chain PFAS adsorption is unaffected. Smaller organic matter fractions (<3 kDa) inhibit short-chain PFAS adsorption, while the hydrophobic neutral fraction strongly limits long-chain PFAS removal.
Our findings suggest that optimizing the removal of specific organic matter fractions before activated carbon treatment can significantly enhance PFAS adsorption efficiency. For treatment plants focused on removing short-chain PFAS, operators should account for seasonal temperature variations, as these can impact removal effectiveness. This study offers valuable insights to improve PFAS removal in drinking water treatment, supporting alignment with proposed regulatory standards.

4.07.B.T-02 Polymer Composite Membrane Processes for Treatment of Contaminants of Emerging Concern in Effluents of Urban Wastewater Treatment Facilities
Marzhan Kalmakhanova[1], *Assel Kurtebayeva*[1] *and Helder Gomes*[2], *(1)M. Kh. Dulaty Taraz University, Kazakhstan, (2)Polytechnic Institute of Bragança, Portugal*
Freshwater is increasingly threatened by pollution and diminishing supplies, particularly from industrial wastewater and municipal sewage. Wastewater treatment plants (WWTPs) use biological processes to purify sewage before discharge into surface waters. However, treated effluents often contain contaminants of emerging concern (CEC), such as pharmaceuticals, personal care products, drugs, and steroid hormones, which pose risks to aquatic organisms and drinking water sources. Various treatment methods have been explored, including activated carbon filtration, advanced oxidation processes (AOPs), membrane filtration, chemical precipitation, ion exchange, adsorption, phytoremediation, electrochemical treatment, and source control. However, many of these methods suffer from limitations such as low efficiency or high costs. As freshwater availability decreases in regions like Central Asia, there is an urgent need for low-cost, reliable, and robust wastewater treatment methods for the safe reuse of treated wastewater, especially for irrigation and other uses. Catalytic wet peroxide oxidation (CWPO) is a promising advanced oxidation process for degrading organic pollutants under mild conditions, using inexpensive clay- and carbon-based catalysts. Membrane technologies also show potential for CEC removal, offering high separation efficiency. Combining polymers with clay- or carbon-based materials enhances removal through filtration and adsorption. This study quantified CECs in southern Kazakhstan using polar organic chemical integrative samplers (POCIS) and proposed solutions using polymer-mixed composite membrane-based processes. These low-cost, sustainable membranes present an environmentally friendly option for wastewater treatment. Sampling surface waters in the south region of Kazakhstan, dominated by the discharge of effluents from urban WWTP, identified 16 CECs, including caffeine, 1,7-dimethylxanthine, paracetamol, cotinine, and sulfamethoxazole (SMX). To present solutions for the removal of CECs, polymer-mixed composite membrane processes were tested considering organoclays and $MnFe_2O_4$ clays produced from natural clays, to be used as filler materials in the membrane processes. The composite polymeric clay-based membranes have shown promising results, with the incorporation of Shymkent organoclay and $MnFe_2O_4$/Turkistan clay proving high adsorption of SMX used as the model pollutant.

4.07.B.T-03 Enhancing Wastewater Quality through SAT Systems: Assessing the Effectiveness of Natural Reactive Barriers for Contaminants Removal
Juan Carrizo[1], *Karen Paola Sepulveda*[2], *Montserrat Folch*[2], *Cristina Valhondo*[3], *Cristina Garcia-Aljaro*[4], *Lurdes Martinez-Landa*[5], *Jesus Carrera*[3] *and Silvia Diaz-Cruz*[6], *(1)IDAEA, Spain, (2)Department of Biology, Healthcare and the Environment, Faculty of Pharmacy and Food Science, University of Barcelona, Spain, (3)Institute of Environmental Assessment and Water Research - Spanish Council for Scientific Research (IDAEA-CSIC), Spain, (4)Dept. Genetics, Microbiology and Statistics, Faculty of Biology; University of Barcelona, Spain, (5)Dept. of Civil and Environmental Engineering. Universitat Politècnica de Catalunya, Barcelona, Spain. Associated Unit: Hydrogeology Group (UPC-CSIC), Spain, (6)Environmental Chemistry Department, Institute of Environmental Assessment and Water Research (IDAEA), Severo Ochoa Excellence Center, Spanish Council for Scientific Research (CSIC), Barcelona, Spain, Spain*

Water scarcity and the presence of contaminants of emerging concern (CECs) in treated wastewater pose significant challenges to water reuse strategies. This study evaluates the effectiveness of a Soil Aquifer Treatment (SAT) system with reactive barriers in removing CECs from urban wastewater treatment plant effluent used for aquifer recharge in Palamós, Spain. We compared two SAT systems: a control filled with sand (B2) and one incorporating a reactive barrier (B3) composed of sand, organic matter, biochar, zeolite, and clay, with samples collected at depths of 15, 28, 41 and 54 cm. Using High-Resolution Mass Spectrometry (HRMS) with Non-Target Analysis (NTA), we analyzed water and barrier samples over a 73-day period. Results showed that B3 exhibited higher CEC detection (320 compounds) compared to B2 (212 compounds), attributed to enhanced adsorption and surface area. Water analysis revealed lower CEC numbers in both systems post-treatment, particularly in B3, indicating more effective removal. However, some compounds increased after treatment, especially in B3, suggesting potential metabolite or transformation product formation within the reactive barrier. The study demonstrates the potential of reactive barriers in SAT systems for enhancing water quality and addressing water scarcity, while highlighting the need for further research on barrier optimization and transformation product formation. These findings contribute to advancing treatment strategies for organic micropollutants in water reuse application.

4.07.B.T-04 Removal of Antibiotics and Nutrients by Microalgae-Bacteria Consortia

***Ornrumpha Sethanunt*[1]*, James P.J. Chong*[2] *and Thierry Tonon*[2]*, (1)University of York, York, United Kingdom, (2)Department of Biology, University of York, United Kingdom*

The persistence of pharmaceutical contaminants in aquatic ecosystems has raised significant environmental concerns due to the accumulation of antibiotics in water bodies. Traditional wastewater treatments often fail to remove these contaminants fully, so exploring alternative bioremediation strategies is essential. The current study investigates the potential of co-cultivating *Chlorella sorokiniana* and bacteria isolated using an iChip system to enhance the removal of antibiotics and nutrients from contaminated water. Laboratory experiments assessed the removal efficiency of ten antibiotics Penicillin V (PenV), Oxytetracycline (OTC), Amoxicillin (AMX), Cephalexin (CEX), Ciprofloxacin (CIP), Metronidazole (MTZ), Clarithromycin (CLR), Azithromycin (AZM), Sulfamethoxazole (SMX), and Trimethoprim (TMP) alongside nutrient analysis for ammonium, nitrate, phosphate, and chemical oxygen demand (COD) over 21 days.

The co-cultivation treatments achieved high % removal for key antibiotics, with PenV, OTC, AMX, and CEX showing removal efficiencies above 90%, while moderate removal rates were recorded for AZM, CIP, and CLR (up to 50%), and lower rates for MTZ, SMX, and TMP. Nutrient removal in the co-culture reached 96% for COD, 32% for nitrate, and 100% for phosphate after 21 days. This suggests that the co-culture system facilitated efficient nutrient recycling, possibly through mutualistic interactions where microalgae provided oxygen to enhance bacterial degradation, and bacteria supplied CO? for algal photosynthesis. Bacterial community analysis further highlighted significant shifts in microbial composition in the presence of algae and antibiotics.

The results of microalgae-bacteria consortia effectively removing antibiotic contaminants and nutrients suggest that this sustainable approach could be integral to future water treatment and management systems. This study contributes valuable insights into optimising bioremediation strategies for pharmaceutical and nutrient contaminant removal in aquatic environments, positioning microalgal-bacterial systems as an efficient solution to improve water quality and mitigate pharmaceutical pollution.

4.07.P-Mo349 Biotransformation and Biodefluorination of n:3 Fluorotelomer Acids in Sludge-Derived Enrichment Culture

***Anindya Dey*[1]*, Dan Wang*[1]*, Ju Zhang*[2]*, Nancy Perreault*[3] *and Jinxia Liu*[1]*, (1)McGill University, Canada, (2)Civil Engineering, McGill University, Canada, (3)National Research Council Canada, Canada*

The extensive use of per- and poly-fluoroalkyl substances (PFAS) in various industries has led to significant environmental contamination, particularly from fluorotelomer-based aqueous film-forming foams (AFFF). This study investigates the biodefluorination capabilities of a unique microbial consortium derived from activated sludge, focusing on its ability to transform n:3 fluorotelomer carboxylic acids (n:3 acids). Previous research identified one-carbon removal pathways as key mechanisms for the stepwise biodegradation and defluorination of select fluorotelomers; however, an enrichment culture and a comprehensive understanding of these biotransformation processes were lacking.

We maintained this enrichment culture over 13 generations, demonstrating sustained defluorination efficiencies of 17% for 5:3 acid and 15% for 4:3 acid. In a detailed experiment conducted over one generation, we incubated the culture for up to 62 days. The culture exhibited logarithmic growth and stable pH, with notable reductions in initial acid concentrations of 46% and 84% after 10 days during the exponential growth phase. Additionally, we explored the unusual incorporation of 5:3 acid into biomass

during the logarithmic growth phase, revealing that 90-97% of the acid was retained during exponential growth. The differential results from two extraction methods suggest a reversible integration mechanism likely involving covalent bonding rather than simple biosorption.
Transformation products, including shorter-chain n:3 acids, short-chain perfluoroalkyl acids and other intermediates, were identified using ultra-high performance liquid chromatography coupled with high-resolution mass spectrometry (UHPLC-HRMS), underscoring the complexity of PFAS biotransformation pathways. Our metagenomic analysis further elucidates the microbial communities involved in defluorination, providing valuable insights into potential defluorinating enzymes and metabolic pathways. While we have yet to fully identify the key microbial players responsible for effectively degrading these highly fluorinated compounds, continued analysis of the metagenomic data promises to uncover critical information for future investigations. These findings enhance our understanding of natural attenuation processes and inform the potential for the biological treatment of polyfluorinated chemicals.

4.07.P-Mo353 Sorption and Biodegradation of Organic Micropollutants in Aerobic Granular Sludge
***Nora B. Sutton**[1], Zhaolu Feng[1], Heike Schmitt[2] and Mark van Loosdrecht[2], (1)Environmental Technology, Wageningen University & Research (WUR), Netherlands, (2)Department of Biotechnology, Delft University of Technology, Netherlands*
Aerobic Granular Sludge (AGS) is a relatively new approach to wastewater treatment. As opposed to activated sludge with mainly flocculant biomass of relatively even composition, the granules in AGS differ in size and composition. Biomass ranges from flocs similar to activated sludge to granules of >6 mm. Granules also have distinct biomass due to the stratification of redox conditions across the granules. Typically organic micropollutants (OMPs) are removed via sorption and biodegradation during wastewater treatment, however this has yet to be thoroughly invested for AGS systems. We hypothesized that different sized granules have potentially different sorption behaviour due to the differences in extracellular polymeric substances (EPS) and have different biodegradation patterns due to the differences in biomass composition among size fractions. Therefore, we investigated the capacity of AGS to remove OMPs via sorption and biodegradation by performing controlled batch experiments in the lab. We separated the sludge into different sizes in order to understand the role of different sludge composition on OMP removal.
We observed notable sorption (>40% removal) for 10 of the 24 OMPs tested in our study (Figure 1). The 10 OMPs include 3 fluoroquinolones (norfloxacin, ofloxacin, and ciprofloxacin), 3 macrolides (clarithromycin, azithromycin, and erythromycin), 2 beta-blockers (propranolol and atenolol), tetracycline, and citalopram. We noted that all of these 10 compounds are ionizable, with 6 positively charged compounds and 4 zwitterionic compounds at pH 7. Considering that sludge biomass typically has a negative charge, this seems to indicate electrostatic interactions between the 10 OMPs and the sludge. Larger fractions contributed more to sorption than smaller granules and flocs, as expressed per unit of biomass. Specifically, the normalized Kd¬ for large fractions was up to 100%larger than for small fractions, suggesting that larger fractions contribute more to sorption in real AGS systems than smaller fractions and flocs. However, sorption kinetics were most likely retarded by diffusion limitations in large granules. Biodegradation was observed for a number of compounds. Overall, this study elucidated the roles of sorption and biodegradation in the removal of OMPs in AGS WWTPs, showing that these processes are size fraction dependent.

4.07.P-Mo362 Phytotoxicity as a Tool for Evaluating Toxin Removal from Industrial Waste Following EGSB Reactor Operation
***Caroline Varella Rodrigues**[1], Mayara Caroline Felipe[1], Sandra Imaculada Maintinguer[2], Edson Luiz Silva[3] and Maria Bernadete Amâncio Varesche[4], (1)University of São Paulo (USP), Brazil, (2) São Paulo State University (UNESP), Brazil, (3)Federal University of São Carlos (UFSCar), Brazil, (4)University of São Paulo, Brazil*
The wet coffee bean processing generates two main wastes: solid lignocellulosic material (husk and pulp) and wastewater. With Brazil producing 3.6 million tons of coffee annually, this results in 27 to 432 million tons of solid waste and 1.8 × 10^1? to 5.4 × 10^1? liters of wastewater. Coffee waste is rich in carbohydrates and organic matter but contains toxic polyphenols, leading to environmental issues like aquatic eutrophication if improperly disposed of. Anaerobic digestion presents a promising solution by reducing organic matter and producing bioenergy (CH?). Combining coffee residues with brewery wastewater can

enhance biogas production, as polyphenols are diluted, improving organic matter utilization. Brewery wastewater production is substantial, with 10-30 m³ of water used per ton of beer, yielding 10-20 m³ of wastewater. Expanded Granular Sludge Bed (EGSB) reactors are effective for wastewater treatment, enhancing COD removal through bed expansion, improving organic matter reduction. To confirm the efficiency of anaerobic digestion in reducing toxicity, phytotoxicity studies provide a reliable assessment tool. This study investigated the effluent from an EGSB reactor using phytotoxicity assays to evaluate its efficiency in treating the combined wastes.

4.07.P Advancing Treatment of Organic Micropollutants in Water and Wastewater

4.07.P-Mo345 Characterization and Removal of Contaminants of Emerging Concern (CECs) During the Biological Treatment of Wastewater Batches from Individual Wastewater Treatment Systems

*Adrian Ferreiro[1], Alberto Suarez[1], **Paula Yumi Takeda**[2], Marcia Helena Rissato Zamariolli Damianovic[2], Francisco Omil[1], Sonia Suarez[3] and Juan Manuel Garrido[1], (1)University of Santiago de Compostela, Spain, (2)University of São Paulo, Brazil, (3)University of Santiago de Compostela, Spain*

Approximately 11% of the European Union population is not connected to sewage collection systems, especially in rural areas (Eurostat 2019), which can be a source of diffuse pollution. Among individual wastewater treatment/collection systems, septic tanks and holding tanks are widely used in Spain. Wastewater and sludge from these systems exhibit higher COD, total nitrogen (TN) and phosphorus concentrations compared to municipal sewage. Moreover, Information regarding contaminants of emerging concern (CECs) in these streams is scarce.

In this study, wastewater batches purged from holding tanks were treated using two lab-scale systems: an Upflow Anaerobic Sludge Bed (UASB) reactor and a Conventional Activated Sludge (CAS) reactor, both operated for almost 90 days under a hydraulic retention time of 1.37 ± 0.51 days. The average inlet COD and TN concentrations were 968 mg COD/L and 142 mg N/L, which are approximately twice as high as those typically found in urban wastewater. COD removal efficiencies were quite similar in both reactors (73 ± 7% in CAS vs. 76 ± 10% in UASB). Nitrification-denitrification was achieved in the CAS unit by alternating cycles of aeration and anoxia, being achieved a total nitrogen removal of 27 ± 13%, with nitrate as the predominant N form in the effluent.

Seven antibiotics, erythromycin (ERY), clarithromycin (CLA), roxithromycin (ROX), azithromycin (AZY), sulfamethoxazole (SMX), trimethoprim (TMP), and ciprofloxacin (CIP), were detected in concentrations of 0.1-10 ?g/L, with CIP and AZY exhibiting the highest values. Anti-inflammatories ibuprofen (IBP), naproxen (NPX) and diclofenac (DCF) were also detected, with IBP reaching up to 35 ?g/L. Removal varied under different reactor conditions: under aerobic/anoxic (CAS) five CECs were removed beyond 70% (ERY, ROX, SMX, IBP and NPX), while under anaerobic conditions only three were effectively removed (ROX, TMP and NPX). DCF is the most recalcitrant compound and the macrolide AZY was removed to a very low extent in both reactors.

These findings highlight the challenges posed by wastewater management in rural areas, which should be addressed taking into account all the complexity present in these streams, particularly due to the presence of CECs.

Disclaimer/Disclosure: Agencia Estatal de Investigación, Ministerio de Ciencia e Innovacion through the ARES Project, Reference: PID2022-141203OB-I00.Project funded by MCIN/AEI/10.13039/501100011033/FEDER, EU.

4.07.P-Mo346 Wide-Scope Suspect Screening of 24 Sewage Treatment Plants

*Tessa E. Pronk[1], Erik Emke[1], Stefan Kools[1], **Nienke Meekel**[2] and Frederic Been[2], (1)KWR Water Research Institute, Netherlands, (2)KWR Water Research Institute | Vrije Universiteit Amsterdam, Netherlands*

Sewage treatment plants (STP) affect water quality by discharging effluent by emitting nutrients and micropollutants. We will present measurements on 24 STPs in The Netherlands on both influent and effluent using wide-scope suspect screening. Our aim was to include known substances, emerging substances and (potential) Substances of Very High Concern. Influent mainly contained substances of human origin, sweeteners, medicines and industrial substances. In total, approximately 15,000 substances were found, of which 353 substances have been identified with high confidence (level 1-2). Of these, 168 substances are linked to a category that indicates the origin. Relatively speaking, medicines are the most frequently detected (118 substances), followed by industrial and household substances (39) and a small group of pesticides, including biocides (11). Six 'Substances of Very High Concern' and four potentially

Substances of Very High Concern have been determined: such as PFBS, a type of PFAS and tetraglyme (solvent). Some drug metabolites may be formed in WWTPs. All WWTPs seem to have many similarities in the disposal of substances, while the differences may be explained by using additional information.

4.07.P-Mo347 Understanding the Influence of Micro and Nano Plastics (PP, PE, and PS) on MBR Performance: A Comprehensive Study

*Junkal Landaburu-Aguirre[1], Francesca Nonnoi[1], Anamary Pompa-Pernia[1], Serena Molina[1] and **Imane Fellahi**[2], (1)IMDEA Water Institute, Spain, (2)IMDEA Water Institute Chemical Engineering Department, University of Alcala, Spain*

Introduction. Microplastics and Nanoplastics (MNPs) pose a pressing environmental concern as they inevitably infiltrate wastewater treatment plants (WWTPs), spreading into aquatic and terrestrial ecosystems through water reuse and sludge application. Membrane Bioreactors (MBRs) have demonstrated high efficiency in removing MPs, achieving rates as high as 99.9%. However, significant gaps persist in understanding the removal dynamics of MNPs and their long-term effects on MBR performance. While studies have examined individual MNPs, the combined impact of mixed plastics such as polyethylene (PE) and polypropylene (PP) microplastics with polystyrene (PS) nanoplastics remains largely unexplored. In this context, this study seeks to fill this critical research gap by investigating the removal efficiency and the synergistic impacts of the accumulation of these mixed plastics on water quality, the floc characteristics, microbial community, and fouling behavior, within a submerged integrated aerated membrane bioreactor system.

Experimental/methodology. The experiments were conducted in a laboratory scale fully automatic aerobic MBR that contains two independent tanks and an effective flat sheet membrane. The systems were seeded with aerobic sludge that was collected from the aeration basin of a WWTP located in Guadalajara (Spain) and was daily fed with synthetic wastewater. One reactor was used as a control , and the other one contained the addition of NP-PS, MP-PP and a recycled MP-PE. The study spans 120 days, including an initial acclimatization phase.
Results and discussion. Preliminary findings revealed that both MBR systems achieved high organic removal efficiencies, with COD reduction exceeding 97%. MP accumulation influenced the microbial structure and diversity, with the microbial community adapting over time under MNP stress. Moreover, MPs demonstrated a potential scouring effect on the membrane, as indicated by trends observed in the TMP profile analysis. Further analyses, including EPS characterization, detailed membrane fouling quantification, and MNP assessment results will provide a more comprehensive understanding of these interactions.
These analyses will contribute to a comprehensive understanding of the interactions between MNPs and the biological and physicochemical components of the treatment process, thereby informing effective mitigation strategies and advancing our knowledge of MNPs removal in MBRs wastewater treatment systems.

4.07.P-Mo349 Biotransformation and Biodefluorination of n:3 Fluorotelomer Acids in Sludge-Derived Enrichment Culture

***Anindya Dey**[1], Dan Wang[1], Ju Zhang[2], Nancy Nancy Perreault[3] and Jinxia Liu[1], (1)McGill University, Canada, (2)Civil Engineering, McGill University, Canada, (3)National Research Council Canada, Canada*

The extensive use of per- and poly-fluoroalkyl substances (PFAS) in various industries has led to significant environmental contamination, particularly from fluorotelomer-based aqueous film-forming foams (AFFF). This study investigates the biodefluorination capabilities of a unique microbial consortium derived from activated sludge, focusing on its ability to transform n:3 fluorotelomer carboxylic acids (n:3 acids). Previous research identified one-carbon removal pathways as key mechanisms for the stepwise biodegradation and defluorination of select fluorotelomers; however, an enrichment culture and a comprehensive understanding of these biotransformation processes were lacking.
We maintained this enrichment culture over 13 generations, demonstrating sustained defluorination efficiencies of 17% for 5:3 acid and 15% for 4:3 acid. In a detailed experiment conducted over one generation, we incubated the culture for up to 62 days. The culture exhibited logarithmic growth and

stable pH, with notable reductions in initial acid concentrations of 46% and 84% after 10 days during the exponential growth phase. Additionally, we explored the unusual incorporation of 5:3 acid into biomass during the logarithmic growth phase, revealing that 90-97% of the acid was retained during exponential growth. The differential results from two extraction methods suggest a reversible integration mechanism likely involving covalent bonding rather than simple biosorption.

Transformation products, including shorter-chain n:3 acids, short-chain perfluoroalkyl acids and other intermediates, were identified using ultra-high performance liquid chromatography coupled with high-resolution mass spectrometry (UHPLC-HRMS), underscoring the complexity of PFAS biotransformation pathways. Our metagenomic analysis further elucidates the microbial communities involved in defluorination, providing valuable insights into potential defluorinating enzymes and metabolic pathways. While we have yet to fully identify the key microbial players responsible for effectively degrading these highly fluorinated compounds, continued analysis of the metagenomic data promises to uncover critical information for future investigations. These findings enhance our understanding of natural attenuation processes and inform the potential for the biological treatment of polyfluorinated chemicals.

4.07.P-Mo351 Can Wastewater Treatment Plants' Mitigate Microplastic Contaminations? – A Comparative Study of Sludge Treatments.

Asta Hooge Poulsen[1]*, Gry Lyngsie*[1]*, Henrik Hauggaard-Nielsen*[2] *and Kristian Syberg*[3]*, (1)Roskilde University, Denmark, (2)Roskilde University, Denmark, (3)DSE, Roskilde University, Roskilde, Denmark*

The primary objective of this study is to quantify the efficiency of various sludge treatment methods in removing microplastics (MP) from sewage sludge at wastewater treatment plants (WWTPs). Given that approximately 99% of MPs entering WWTPs are retained in the sludge fraction, understanding the effectiveness of these treatments is critical for mitigating the environmental risks associated with the application of sludge as fertilizer in agricultural fields.

This study evaluates the effectiveness of different sludge treatment technologies in reducing MP concentrations in sludge. The assessment involves analyzing sludge samples collected before and after treatment from five different WWTPs. The sludge treatments examined include thermal processes (incineration, pyrolysis), anaerobic digestion and mechanical dewatering processes.

The analysis of plastic polymers and their concentrations is conducted using Fourier-transform infrared spectroscopy (FTIR).

This study contributes to increasing knowledge regarding the management of MPs in wastewater treatment processes. By systematically evaluating the efficiency of sludge treatment technologies in MP removal, this research provides essential insights that can inform best practices for WWTP operations and the sustainable use of treated sludge in agriculture. The findings give important insight into the of selecting appropriate treatment methods at WWTPs to mitigate the environmental impacts of microplastics on terrestrial ecosystem and promote safer agricultural practices.

4.07.P-Mo352 Effect of Thermal Hydrolysis on the Behaviour of Target Organic Micropollutants in Sewage Sludge

Andrea Deiana*, Merle de Kreuk and Jules van Lier, Section Sanitary Engineering, Department of Water Management, Delft University of Technology, Netherlands*

Growing concerns about organic micropollutants (OMPs) in sewage sludge (SS) are affecting its management strategy and disposal practices. Whilst, recovering nutrients and organic matter from digested SS for agricultural use is widely considered a positive contribution to the circular economy. One of the main concerns is that OMPs, such as pharmaceuticals, antibiotics and pesticides, may negatively affect environmental and human health when digested SS is used in agriculture.

Several pre-treatment technologies have been developed to stabilise and hygienise SS, to improve its dewatering and to facilitate its final disposal. Among these, the thermal hydrolysis process (THP) has proven effective in improving methane production in SS digestion, digestate dewaterability and pathogen removal. However, the fate of OMPs during and after THP is not yet fully understood. Some pollutants might degrade during the treatment, others might react with the present organic compounds.

This study investigates the behaviour of three target OMPs during THP, operated at temperatures of 160 200 °C, simulating the conditions in commercial THPs for sludge pre-treatment prior to anaerobic digestion. The persistence of the target OMPs will be assessed with analytical methods in both water with representative organic compounds and spiked SS samples, to understand the differences in the adsorption of different OMPs, characterised by comparable chemical properties. Moreover, the biochemical methane potential of the treated samples will be determined to assess the final biodegradation of the formed and/or residual compounds. We hypothesize that the OMPs will be better reduced after thermal treatment, because they will be (partially) degraded at the high temperatures, or they will be desorbed from the solid

sludge particles becoming available for biodegradation. Additionally, the desorbed compounds may react with other organic matter. The experimental results on the persistence of the thermally treated target compounds will be presented, along with findings from experiments using sewage sludge spiked with these three compounds and exposed to THP conditions.
By focusing on the potential interactions of the OMPs with recalcitrant organic compounds present in SS during the treatment, this research could pave the way for an improved (thermal) treatment process for SS that will also address the removal of OMPs and enhance the potential for direct reuse of the solid or liquid fraction.

Disclaimer/Disclosure: This research is funded by the EU Framework Program for Research and Innovation Horizon Europe under grant agreement no. 101120427 (HORIZON-MSCA INCLUE).

4.07.P-Mo353 Sorption and Biodegradation of Organic Micropollutants in Aerobic Granular Sludge
***Nora B. Sutton*[1]*, Zhaolu Feng[1], Heike Schmitt[2] and Mark van Loosdrecht[2], (1)Environmental Technology, Wageningen University & Research (WUR), Netherlands, (2)Department of Biotechnology, Delft University of Technology, Netherlands*
Aerobic Granular Sludge (AGS) is a relatively new approach to wastewater treatment. As opposed to activated sludge with mainly flocculant biomass of relatively even composition, the granules in AGS differ in size and composition. Biomass ranges from flocs similar to activated sludge to granules of >6 mm. Granules also have distinct biomass due to the stratification of redox conditions across the granules. Typically organic micropollutants (OMPs) are removed via sorption and biodegradation during wastewater treatment, however this has yet to be thoroughly invested for AGS systems. We hypothesized that different sized granules have potentially different sorption behaviour due to the differences in extracellular polymeric substances (EPS) and have different biodegradation patterns due to the differences in biomass composition among size fractions. Therefore, we investigated the capacity of AGS to remove OMPs via sorption and biodegradation by performing controlled batch experiments in the lab. We separated the sludge into different sizes in order to understand the role of different sludge composition on OMP removal.
We observed notable sorption (>40% removal) for 10 of the 24 OMPs tested in our study (Figure 1). The 10 OMPs include 3 fluoroquinolones (norfloxacin, ofloxacin, and ciprofloxacin), 3 macrolides (clarithromycin, azithromycin, and erythromycin), 2 beta-blockers (propranolol and atenolol), tetracycline, and citalopram. We noted that all of these 10 compounds are ionizable, with 6 positvely charged compounds and 4 zwitterionic compounds at pH 7. Considering that sludge biomass typically has a negative charge, this seems to indicate electrostatic interactions between the 10 OMPs and the sludge. Larger fractions contributed more to sorption than smaller granules and flocs, as expressed per unit of biomass. Specifically, the normalized Kd¬ for large fractions was up to 100%larger than for small fractions, suggesting that larger fractions contribute more to sorption in real AGS systems than smaller fractions and flocs. However, sorption kinetics were most likely retarded by diffusion limitations in large granules. Biodegradation was observed for a number of compounds. Overall, this study illucdated the roles of sorption and biodegradation in the removal of OMPs in AGS WWTPs, showing that these processes are size fraction dependent.

4.07.P-Mo354 Removal of Persistent, Mobile, Organic Compounds (PMOC) Using Activated Sludge-Based Hydrochars in a Decentralized Municipal Wastewater System
***Sampriti Chaudhuri*[1]*, Lisa Rover[2], Maria Balda[1], Anett Georgi[1], Martin Krauss[3] and Ariette Schierz[1], (1)Department of Technical Biogeochemistry, Helmholtz Centre for Environmental Research GmbH UFZ, Germany, (2)Department of Biorefineries, Deutsches Biomasseforschungszentrum gemeinnutzige GmbH DBFZ, Germany, (3)Department of Exposure Science, Helmholtz Centre for Environmental Research (UFZ), Germany*
Existing decentralized wastewater treatment systems already meet legal standards for water quality parameters (EU 2020/741). However, recent studies have demonstrated the uptake of persistent, mobile, organic compounds (PMOC) such as pharmaceuticals, tire additives and industrial chemicals by irrigated crops, raising concerns about human exposure through food consumption. The revised EU Urban Wastewater Treatment Directive (UWWTD 2024) outlines the need to include a quaternary treatment step that addresses micropollutants for safe water reuse in urban areas.
Hydrothermal carbonization (HTC) is a promising technology for the treatment of wet biological waste - it can recover nutrients and produce hydrochar, a carbon-rich solid residue with multiple applications. The aim of this study is to develop a sustainable sorbent from HTC of sewage sludge for the removal of PMOC from municipal wastewater. Sewage sludge, either alone or in combination with manure and seasonal biomass, is subjected to temperatures of 180-280°C and pressures of 10-65 bar to produce

hydrochar. The resulting hydrochar is activated by steam in a N2 atmosphere at temperatures between 800 and 900°C for 1-4 hours to increase its carbonization and micro- and mesoporosity, which is beneficial for PMOC sorption. Preliminary results from sorption studies using 8 different activated sludge-based hydrochars show efficient removal of model PMOC perfluorobutanoic acid, perfluorooctanoic acid and sulfamethoxazole (logarithmic sorption coefficients Kd ranging between 3.3 to 5.4 for PMOC concentrations of 40 to 150 µg/L). The results also indicate that a de-functionalized, micro- and mesoporous sorbent performs best in terms of sorption of these compounds.
The best-performing activated hydrochar will be tested at an existing pilot site where wastewater from 8 population equivalents is treated by an aerated constructed wetland (CW). Water from the CW will pass through a slow trickling sand filter to reduce the bacterial load, followed by the reactor packed with the tailored activated hydrochar to remove residual PMOC. The final water quality from the decentralized treatment system is expected to be suitable for horticulture thereby improving water resilience in urban areas.

4.07.P-Mo355 Biochar as a Green Remediation Approach for Per- and Polyfluoroalkyl Substances in Contaminated Stormwater

***Alberto Celma**[1], Aleksandra Skrobonja[2], Lutz Ahrens[1] and Karin Wiberg[1], (1)Department of Aquatic Sciences and Assessment, Swedish University of Agricultural Sciences (SLU), Sweden, (2)Vinca Institute for Nuclear Sciences, University of Belgrade, Serbia*

Pyrolyzed organic matter, also known as biochar, has recently shown strong potential as a treatment solution for sorption of organic micropollutants in contaminated water. Biochar generally consists of a complex structure of carbonaceous fibers with different chemical composition and physical properties depending on the feeding material used for the pyrolysis. Due to its intrinsic hydrophobic characteristics as well as a variety of chemical moieties on its surface, biochar has been proved valuable for soil function improvement, by retaining nutrients and contaminants. In this study, we aim to evaluate the potential removal of per- and polyfluoroalkyl substances (PFAS) using biochar as a green remediation strategy for PFAS-polluted stormwater systems. To that end, different biochar materials (both commercial and research-based), as well as different feedstock (e.g. forest biomass, seed waste, sewage sludge) have been tested. At first, static flow systems were carried out over 7 days in a set of 12 different biochar materials to screen for the best performing ones as a pre-selection for the subsequent experiments. As the next step, 5 selected materials were used for filter tests in a constant-flow column experimental set-up. With the final goal of identifying retention rates as well as breakthrough levels for the 15 PFAS tested, the columns were constantly running over a period of 69 days. Our observations indicated that there were large differences in the biochar performance when it comes to the retention rates of the tested PFAS contaminants. Some materials, either plant- or sludge-based, showed relevant capacity to remediate PFAS from polluted stormwater in the long term, while others showed a poor performance to adsorb PFAS. Thus, biochar performance for removal of PFAS depends, among others, on both the feeding material and production conditions. Overall, static flow tests showed a very promising application of biochar as a remediation tool for PFAS with some materials reaching removal efficiencies up to 99% in static systems. Also, long-chain PFAS showed a stronger sorption to the biochar compared to short-chain PFAS. For the dynamic flow systems, similar observations were achieved. Short-chain PFAS tended to remain in the aqueous phase and, thus, column breakthrough occurred at an earlier stage. However, overall biochar has been proven as a promising and green strategy for the removal of PFAS from polluted stormwater.

4.07.P-Mo356 Understanding Sorption and Enhancing Sorption of OMPs in Soils to Optimize Nature-Based OMP Removal in Drinking Water Treatment

***Anne van Dalen**[1], Gabriel Sigmund[2], Nora B. Sutton[3] and Thomas Wagner[1], (1)Wageningen University and Research (WUR), Netherlands, (2)EDGE, Wageningen University and Research (WUR), Wageningen, Netherlands, (3)Environmental Technology, Wageningen University and Research (WUR), Wageningen, Netherlands*

Organic micropollutants (OMPs) at trace level in surface waters can threaten sources for drinking waters. Soil passage is a commonly used nature-based pre-treatment of surface water used in drinking water production. Previous studies have shown that certain OMPs can be removed during soil passage, whilst other OMPs are not removed. Also, removal efficiencies can vary greatly between different locations. Sorption to soil is hypothesized to be an important OMP removal mechanism. Especially for OMPs that are ionizable at environmentally relevant pH, sorption behavior is not well understood. Also, the lack of reliable experimental data hinders the development of reliable predictive models for OMP sorption.

We here present insights from sorption tests that were carried out according to the OECD-106 guideline on sorption-desorption batch experiments with different soils and over 60 OMPs (including pharmaceuticals, pesticides, industrial chemicals, PFAS) that were selected based on their occurrence in Dutch surface waters. Three different soils - cyclone sand, aquifer material from 7-8m depth and infiltration pond material from 0-1m depth were tested for their OMP sorption. The cyclone sand was a washed sand acting as a blank sandy soil, whereas the aquifer and infiltration pond sediment represented Dutch drinking water aquifers and soil passage, respectively. Secondly, green sorbent amendments biochar, peat, and iron sludge from rapid sand filters - were added to these three soils to explore how sorption of mobile OMPs could be enhanced in the soil passage. These sorbents were tested to identify the most suitable material for field application, balancing practical considerations and enhanced sorption. In summary, this study focused on understanding and enhancing the sorption of OMPs to different soils and soil amendments with special attention to ionizable OMPs. The results created a better understanding of OMP sorption to soils - especially charged OMPs- and served as input for the design of lab-scale soil passage systems optimized for OMP removal.

4.07.P-Mo357 Photochemical Degradation of a Mixture of Pharmaceuticals in Wastewater
Sanjeeb Mohapatra[1]*, Tejas N. Vasa*[2]*, Jan Peter van der Hoek*[2] *and Henri Spanjers*[2]*, (1)National University of Singapore (NUS), Singapore, (2)Department of Water Management, Faculty of Civil Engineering and Geosciences, Delft University of Technology, Netherlands*
Organic micropollutants, such as pharmaceuticals, represent a significant environmental and public health challenge due to their persistence, toxicity, and potential to contribute to antimicrobial resistance. These contaminants often pass through conventional wastewater treatment, entering aquatic environments and posing risks to ecosystems and human health. Advanced oxidation processes (AOPs), particularly photoelectrochemical oxidation (PEC), offer a promising solution for removing trace-level pharmaceuticals from secondary-treated wastewater. However, the photocurrent conversion efficiency, catalytic activity, and stability of BiVO4-based photoanodes, which are key components in PEC systems, are still limited. Surface modifications have shown potential to address these challenges and enhance their performance. This study aims to improve the PEC activity of BiVO4-based photoanodes for the degradation of pharmaceutical mixtures in secondary-treated wastewater through surface modification using quaternary ammonium-based compounds (QACs). The photoanodes were fabricated using ultrasonic spray pyrolysis and characterized using techniques such as scanning electron microscop y (SEM), X-ray diffraction (XRD), and linear sweep voltammetry (LSV). PEC experiments were conducted under simulated solar light to assess the degradation of a mixture of pharmaceuticals at an initial concentration of 10 µg/L.

The results demonstrated that the surface modification of BiVO4 with QACs significantly enhanced the degradation rate of pharmaceuticals compared to unmodified BiVO4 photoanodes. SEM images confirmed the successful deposition of needle-like QAC particles on the BiVO4 surface, leading to improved charge separation. Notably, pharmaceuticals such as diclofenac, sulfamethoxazole, sulfadimethoxine, and acetaminophen showed higher removal rates in the presence of the modified photoanodes. This research highlights the potential of QAC-modified BiVO4 photoanodes as an effective approach for enhancing the degradation of pharmaceuticals in wastewater. The findings contribute to advancing the field of PEC-based wastewater treatment technologies and offer promising implications for upscaling and practical application in treating pharmaceutical-contaminated wastewater.

4.07.P-Mo358 Treatment of Pharmaceutical Industry Wastewater Using Peroxydisulfate Activated by Nano-Scale Zero Valent Iron
Adam Loos*, Monika Lavickova, Radek Škarohlíd, Jiri Krouzek and Lenka McGachy, Department of Environmental Chemistry, University of Chemistry and Technology Prague, Czech Republic*
Wastewaters from the pharmaceutical manufacturing contain high concentrations of active pharmaceutical ingredients (APIs) that are resistant to conventional wastewater treatment methods, posing significant environmental risks. Traditional approaches like thermal oxidation and activated carbon sorption face challenges as thermal oxidation is energy-intensive and activated carbon sorption generates secondary waste without addressing degradation. Advanced oxidation processes (AOPs) offer a promising

alternative, with peroxydisulfate (PDS) showing strong potential due to its ability to produce reactive sulfate radicals and other reactive oxygen species. Despite this, its application in API degradation remains relatively under-investigated, with notable gaps, particularly in the context of pharmaceutical wastewaters. This study examines the degradation of the synthetic azasteroid Finasteride in wastewater from its production, using PDS activated by nanoscale sulfidized zero-valent iron (nZVI). Key operational parameters, including temperature, pH, and the presence of scavengers and surfactants, were systematically evaluated. Response surface methodology (RSM) was employed to optimize the system by analysing interactions between variables and their effects on degradation efficiency. Optimal conditions were achieved with an equimolar nZVI-to-PDS ratio and low carbonate concentrations. Interestingly, a molar surplus of nZVI-to-PDS diminished degradation efficiency, revealing a non-linear relationship. Neither initial pH nor chloride concentration significantly affected the process.
These results indicate the potential of PDS/nZVI systems as environmentally sustainable solutions for pharmaceutical wastewater treatment. The findings also highlight the value of RSM in designing and optimizing advanced treatment systems for complex wastewater matrices.

4.07.P-Mo359 Removal of Perfluorooctanoic Acid Using Biopolymer Functionalized Graphene Oxide Nanocomposites: Isotherm, Kinetics, and Thermodynamics

***Byomkesh Mahanty**, Vani Grover, Bhavini Saawarn, Sahid Hussain and Subrata Hait, Indian Institute of Technology Patna, India*

Perfluorooctanoic acid (PFOA) is a recalcitrant emerging organic contaminant from the per- and polyfluoroalkyl substances (PFAS) family that poses serious environmental challenges. PFOA has been extensively produced and utilized across various industries, such as textile and paper coatings, metal plating, semiconductor manufacturing, etc. Its widespread occurrence and significant bioaccumulation have sparked growing global concern, underscoring the urgent need for effective removal strategies. Among existing treatment methods, adsorption has shown considerable effectiveness in removing PFOA, and there is a continued need to develop more efficient adsorbents for this purpose. In this context, this study prepared ultrasonic-assisted chitosan-functionalized graphene oxide (GO-CS) nanocomposites and used it for the removal of PFOA. The surface characteristics of the nanocomposites are tailored by adjusting the chitosan loading amounts to attain optimal performance in PFOA adsorption. Different advanced characterization results confirmed the successful functionalization of graphene oxide with chitosan. In batch experiments, the most effective GO-CS nanocomposite achieved approximately 95% PFOA removal under favorable conditions: an adsorbent dose of 240 mg/L, pH 4, and a contact time of 120 min. Non-linear regression analysis revealed that the adsorption process followed pseudo-second-order kinetics and was best represented by the Langmuir isotherm model, with a maximum adsorption capacity of approximately 642 mg/g. The thermodynamic analysis revealed that the adsorption of PFOA onto the developed adsorbent was spontaneous and exothermic in nature. Spectroscopic and zeta potential analyses confirmed that electrostatic interaction and hydrogen bonding are the primary mechanisms facilitating PFOA adsorption. The regeneration study demonstrated that the developed adsorbent could be reused across multiple regeneration cycles while maintaining significant adsorption performance. This study provides valuable insights into the adsorption behavior of PFOA and highlights the substantial potential of chitosan-functionalized graphene oxide nanocomposites as highly efficient adsorbents for PFOA removal.

4.07.P-Mo360 Preparation of Green Synthesized Nano-Catalyst for the Sono-Catalytic Degradation of Emerging Organic Contaminants

*Shravya C, **Binay Kumar Tripathy** and Keshava Balakrishna, Manipal Institute of Technology, Manipal, India*

Emerging Contaminants (ECs) are group of chemical substance that are resistive to degradation and recently have been detected in surface waterways, groundwater, drinking water, food sources, and municipal wastewater. Trace amounts of ECs such as per-fluorinated compounds (PFCs), per fluorinated alkyl substances (PFAS), perfluorooctanoic acid (PFOA), endocrine disrupting compounds, pharmaceuticals, synthetic dyes, phenolic compounds, microplastics and alkyl benzene sulfonates have been found in most terrestrial and aqueous ecosystem. Due to this, global attention has been drawn to the transport, retention, bioaccumulation, and adverse consequences of ECs that are toxic to human health even at lower concentration. This study aims to improve the degradation rate of ECs from wastewater by using green-synthesized nano-catalyst prepared from lantana camara plant leaf extract under ultrasound radiation. Nanoparticles' distinct physicochemical characteristics allow them to have a significant capacity for adsorption and catalytic degradation of organic compounds. The use of ecologically friendly synthesis methods for nanoparticles is consistent with the increased focus on sustainable and green technologies.

Sono-catalytic study is conducted using an ultrasound reactor to determine the degradation rate of ECs in the presence of nano-catalyst. The green synthesized nanomaterial was prepared by leaf extract from lantana camara with titanium dioxide (TiO2) powder for its application in ECs degradation. Post synthesis, the catalyst was characterized in order to determine its structural characteristics, such as particle size and composition using scanning electron microscope (SEM), transmission electron microscopy (TEM), Energy Dispersive X-Ray (EDX), and Fourier-transform infrared spectroscopy (FTIR). The formation of tetragonal-shaped TiO2 nanoparticles was validated by a variety of characterisation techniques.

Disclaimer/Disclosure: This work is funded by Vision Group of Science and Technology (VGST), Karnataka Science and Technology Promotion Society (KSTePS), Grant No: GRD 1167 (2024-26).

4.07.P-Mo361 Evaluation of the Environmental Toxicity of Wastewater Treated by the Emerging Solar Chlor-Photo-Fenton Process for Reuse in Agricultural Irrigation

Solaima Belachqer-El Attar[1], Paolo Taborelli[2], Paula Soriano-Molina[1], ***Peter Roslev**[2]* *and Jose Antonio Sanchez Perez[1], (1)Solar Energy Research Centre (CIESOL), Joint Centre University of Almer a-CIEMAT, Chemical Engineering Department, University of Almer a, Spain, (2)Department of Chemistry and Bioscience, Section of Bioresources and Process Engineering, Aalborg University, Denmark*

The toxicity of wastewater treated by applying the novel solar chlor-photo-Fenton (SCPF) process has been assessed for the first time. This innovative process, based on the simultaneous supply of hydrogen peroxide (H2O2) and sodium hypochlorite (NaOCl) using ferric nitrilotriacetate (Fe3+-NTA) as an iron source, has shown promising results in terms of disinfection and removal of organic microcontaminants while minimizing disinfection by-products occurrence.

In the present study, secondary effluents from wastewater treatment plants (WWTPs) in Uleila del Campo and El Toyo (Almería, Spain) were treated using the SCPF process with low reagent concentrations: 0.1 mM of Fe3+-NTA (molar ratio 1:1, 5.5 mg/L Fe3+), 0.73 mM of H2O2 (25 mg/L), at different chlorine doses ranging from 0.13 mM (10 mg/L) to 0.39 mM (30 mg/L). Conventional chlorination at comparable chlorine concentrations and solar photo-Fenton were also evaluated in parallel to compare with the novel strategy.

The potential environmental toxicity of the treated wastewater was evaluated using different bioassays. Microbial toxicity was evaluated using the luminescent bacteria test with Aliivibrio fischeri, and a new microrespirometry toxicity test targeting responses of microplankton communities. Phytotoxicity was evaluated using a freshwater algal growth inhibition test with the unicellular green algae *Raphidocelis subcapitata*, and a germination test using emergence of lettuce seedlings (*Lactuca sativa* L.). The genotoxicity of treated wastewater was evaluated using the Umu-C and the Ames fluctuation tests. The traditional bioluminescence inhibition test showed no apparent toxicity regardless of the wastewater treatment process. In contrast, the freshwater algal test showed detectable phytotoxicity in wastewater treated by conventional chlorination, while no or very low phytotoxicity was detected in samples treated with the other processes. The lettuce germination test indicated low phytotoxicity for a few undiluted samples but could be mitigated by dilution. No or very low apparent genotoxicity was detected for the treated wastewater samples. Overall, comparable or lower ecotoxicity and genotoxicity were observed for wastewater treated with SCPF compared to conventional processes. This research sheds light on the application potential of the novel SCPF process and may pave the way for large-scale sustainable applications.

Disclaimer/Disclosure: S. Belachqer-El Attar gratefully thanks the PPIT-University of Almería for her predoctoral research grant (CPRE2023-007) and Junta de Andalucía ERDF 2021 2027 (Program: 54. A). The authors acknowledge the LIFE PHOENIX (LIFE19 ENV/ES/000278) and ANDROMEDA (PID2022-140875OB-C31) projects.

4.07.P-Mo362 Phytotoxicity as a Tool for Evaluating Toxin Removal from Industrial Waste Following EGSB Reactor Operation

***Caroline Varella Rodrigues**[1], Mayara Caroline Felipe[1], Sandra Imaculada Maintinguer[2], Edson Luiz Silva[3] and Maria Bernadete Amâncio Varesche[4], (1)University of S o Paulo (USP), Brazil, (2)S o Paulo State University (UNESP), Brazil, (3)Federal University of S o Carlos (UFSCar), Brazil, (4)University of Sao Paulo, Brazil*

The wet coffee bean processing generates two main wastes: solid lignocellulosic material (husk and pulp) and wastewater. With Brazil producing 3.6 million tons of coffee annually, this results in 27 to 432 million tons of solid waste and 1.8 × 10¹? to 5.4 × 10¹? liters of wastewater. Coffee waste is rich in carbohydrates and organic matter but contains toxic polyphenols, leading to environmental issues like aquatic eutrophication if improperly disposed of. Anaerobic digestion presents a promising solution by reducing organic matter and producing bioenergy (CH?). Combining coffee residues with brewery wastewater can enhance biogas production, as polyphenols are diluted, improving organic matter utilization. Brewery wastewater production is substantial, with 10 30 m³ of water used per ton of beer, yielding 10 20 m³ of wastewater [3]. Expanded Granular Sludge Bed (EGSB) reactors are effective for wastewater treatment, enhancing COD removal through bed expansion, improving organic matter reduction. To confirm the efficiency of anaerobic digestion in reducing toxicity, phytotoxicity studies provide a reliable assessment tool. This study investigated the effluent from an EGSB reactor using phytotoxicity assays to evaluate its efficiency in treating the combined wastes.

4.07.P-Mo363 Assessing Ecotoxicity of Textile Effluents: A Comparative Study of Electrochemical Ozone Oxidation (ECOOP) and Conventional Treatments with Focus on River Ecosystem Impact

Anju Anna John[1], Stella Jennes[2], Jan Halaunia[3], Marius Hinrichs[4], Kannan Aravamudan[1], Henner Hollert[5] and Indumathi M. Nambi[1], (1)IIT Madras, India, (2)Goethe University Frankfurt, Frankfurt, Germany, (3)Evolutionary Ecology & Environmental Toxicology, Goethe University Frankfurt, Frankfurt am Main, Germany, (4)Goethe University Frankfurt, Germany, (5)Evolutionary Ecology and Environmental Toxicology, Goethe University Frankfurt, Germany

The textile industry is one of the significant water-intensive industries in the world that generates 90% of the consumed water as wastewater. Generally, the wastewater discharged from the textile industry contains dyes, heavy metals, scattering materials, acids, alkalis, salts, and detergents. Among these contaminants, it is becoming particularly a challenging problem to degrade dyes due to their complexity. Incomplete removal of these pollutants during conventional treatment processes may result in the discharge of harmful byproducts into the water bodies. This can have detrimental effects on aquatic ecosystems, disrupt food chains, and deteriorate water quality, ultimately causing ecological imbalances. To address the environmental impacts associated with conventional treatment technologies, an electrochemical-based advanced oxidation process called the Electrochemical Ozone oxidation process (ECOOP) was assessed for its efficacy in the complete mineralization of textile effluent. The primary objective was to tailor the treatment process to minimize the formation of undesirable toxic byproducts, making it suitable for safe discharge. Laboratory-scale studies demonstrated that the proposed treatment system could achieve a remarkable 65% removal of total organic carbon (TOC) from real textile effluent. Implementing this system in textile wastewater treatment will have the added benefit of eliminating the need for chlorination, consequently reducing the formation of chlorinated disinfection byproducts. Furthermore, it is crucial to study the potential impacts of contaminants on ecosystems and aquatic organisms. Relying solely on chemical analysis may not provide a complete picture of the toxicity levels of treated wastewater. Therefore, there is a need to develop holistic and impact-oriented methods to assess the ecotoxicity of textile effluents. In this study, ecotoxicological analysis was conducted on samples treated with ECOOP and conventionally treated samples from a CETP. Results revealed differences in toxicity levels, providing valuable insights for assessing the environmental impact of this treatment technology.

4.07.P-Mo364 Spatial Distribution of Pharmaceutical Compounds and Pesticides Concentration in Zarqa River, Jordan

*Aisha Hushki[1], Almoayied Assayed[2] and **Hadeel Hosney**[3], (1)Water, Environment and Climate Change Centre, Royal Scientific Society, Jordan, (2) Water, Environment and Climate Change Centre, Royal Scientific Society, Jordan, (3)Wastewater Treatment and Reuse in Agriculture, Netherlands*

The Zarqa River is critical to Jordan's agricultural supply and social development. It is used to irrigate a variety of crops, including vegetables, fodder crops, trees, and commercial crops. The river is facing tremendous challenges caused by contamination from various sources, including industrial and domestic wastewater overflow. Several WWTPs release treated effluent into the Zarqa River. In addition to these effluents, another significant source of contamination arises from the unregulated consumption of PhACs. Furthermore, industrial discharges from pharmaceutical, pesticide, and fertilizer manufacturing plants, coupled with the improper disposal of expired or unused medications, represent pollutants of concern. These contaminants pose serious risks to aquatic ecosystems in the Zarqa River (ZR) and beyond, impacting both environmental and human health. Therefore, understanding the spatial distribution of these pollutants in ZR is critical for effective environmental management, public health protection, and safe

reuse practices in irrigated agriculture in Jordan Valley.
The study focuses on Assamrah WWTP's great efficiency in removing major physical and chemical water quality factors, with effluent matching Jordanian regulations (JS893/2021) for discharge and agricultural irrigation. The water quality of the Zarqa River and other sample sites was declared appropriate for irrigation of industrial and field crops, as well as forest trees. However, pharmaceutical residues, particularly carbamazepine, showed persistence, with concentrations increasing downstream indicating resistance to breakdown. Ofloxacin and diclofenac were greatly reduced, although pesticide residues such as chlorpyrifos and diazinon had high influent levels that significantly decreased downstream, suggesting effective WWTP treatment and natural dilution. Despite the reductions, stable chemicals such as diuron remained detectable. The absence of THMs demonstrates good management at WWTP.
These findings highlight the widespread prevalence of pharmaceutical and pesticide residues in environmental matrices, necessitating improved treatment technologies, public awareness campaigns, regulatory enforcement, and continued monitoring to reduce their environmental and health effects. The study establishes a vital baseline for regulating OMPs and optimising wastewater treatment systems.

Disclaimer/Disclosure: The IHE Delft Water and Development Partnership Programme, financed by the Dutch Ministry of Foreign Affairs, provided support for this research through the SafeAgroMENA project.

4.07.P-Mo365 Evaluating Organophosphate Flame Retardant (OPFR) Removal in Drinking Water Treatment: A Multi-Site Study in England and Wales

*Chesney Swansborough[1], Emma Goslan[2], Michael Whelan[3], Emma Pemberton[1], Lauren Dawson[1], **Megan Griffith**[1], Nathan Hobbs[1], Emily Bird[1], Sarah Bull[4] and Mick Stanger[5], (1)Ricardo, United Kingdom, (2)Cranfield University, Cranfield, United Kingdom, (3)University of Leicester, United Kingdom, (4)TARA Consulting, United Kingdom, (5)Drinking Water Inspectorate, United Kingdom*

Flame retardants are functional additives designed to prevent ignition or slow fire progression. These chemically diverse substances are crucial for enhancing the fire safety of various products used both in industry and daily life. Organophosphate flame retardants (OPFRs) are commonly used as additives in items such as building materials, electrical devices, and upholstered furniture. Since OPFRs are not chemically bonded to these materials, they can be easily released into the environment, resulting in their widespread detection in both environmental and biological samples. Concerns about OPFRs in drinking water are growing due to their potential health risks, including neurotoxicity, cancer, and endocrine disruption. However, information on OPFR levels in drinking water and the efficacy of current treatment processes in removing these chemicals remains limited.
This study aimed to examine the presence of OPFRs in untreated and treated drinking water and to assess how effectively current treatment processes remove these contaminants at facilities across England and Wales. A risk-based approach was utilised to select three drinking water treatment plants with various water sources and treatment methodologies. Samples were collected at three stages in the treatment process: raw water, intermediate treatment stages, and final drinking water at four intervals throughout 2024. A range of OPFRs were analysed in these samples to better understand their presence and the likelihood of their removal during water treatment. The findings that will be presented from this monitoring program provide insights into the performance of advanced and conventional treatment processes.
The results of this study will inform further monitoring actions to ensure safe water supplies, support the creation of guidance for water companies, and aid in shaping water safety plans. Additionally, the findings will be valuable for future UK policy development concerning these emerging contaminants of concern.

4.07.P-Mo366 Removal of Micropollutants in Phytoparking Pilot: Insights from the MULTISOURCE Project

***Vaidotas Kisielius**[1], Mireille Martens[2], Dion van Oirschot[2], Diederik Rousseau[3] and Pedro N. Carvalho[1], (1)Aarhus University, Department of Environmental Science, Denmark, (2)Rietland BV, Belgium, (3)Ghent University, Belgium*

The EU Horizon 2020 MULTISOURCE project promotes the use of nature-based solutions (NBS) for urban wastewater treatment and reuse across seven diverse pilot sites in Europe and the USA. These pilots showcase Enhanced Natural Treatment Systems (ENTS) designed to improve water quality, promote sustainable reuse, and boost urban resilience to climate change. This study focuses on the Phytoparking pilot in Belgium, an innovative 76 m² dual-stage aerated hybrid wetland implemented at an off-grid campsite. The system efficiently separates and treats grey and black wastewater streams at their source. Over two years of continuous monitoring during the active seasons, the Phytoparking system

demonstrated high performance, achieving >90% removal of many organic micropollutants, including challenging compounds such as carbamazepine (with >50% reduction) and oxazepam (with >30% reduction). It also achieved significant pathogen removal, consistently meeting local discharge standards for BOD, COD, TSS, and pH, as well as Class C criteria under the European Irrigation Regulation EU2020/741 for water reuse.
The Phytoparking pilot's robust operation underscores the potential of NBS to provide effective wastewater treatment solutions that can be integrated into multifunctional urban spaces, such as parking areas. Its success showcases the feasibility of adopting NBS for wider urban applications to enhance water resilience, conserve water resources, and comply with the recently adopted EU Wastewater Treatment Directive. The findings from the Phytoparking system contribute valuable insights into how nature-based solutions can be scaled and integrated into urban and peri-urban areas across Europe and beyond, aligning with global sustainability efforts to mitigate water scarcity and improve ecological resilience while providing economic and societal benefits.

4.07.P-Mo367 Novel Laser Pre-Structured Silicon Filters for Micro- and Nanoplastics Analysis
*Paul-Tiberiu Miclea[1], Hardik Vaghasiya[2], Susanne Gramsall[1], Steffi Goller[1], Piotr Pawlik[3], **Korinna Altmann**[4] and Monika Lelonek[3], (1)Fraunhofer Center for Silicon Photovoltaics, Germany, (2)Martin Luther University Halle-Wittenberg, Germany, (3)SmartMembranes GmbH, Halle(Saale), Germany, (4)Federal Institute for Materials Research and Testing (BAM), Germany*
Microplastics defined according to DIN/TR 21960:2020 as plastic particles in the size range of 0.001 1 mm have become a pervasive and concerning pollutant in aquatic environments worldwide. It originates from a variety of sources, including plastic debris fragmentation, microbead abrasion, and synthetic fiber shedding, and these minute particles pose significant threats to marine ecosystems, wildlife, and human health. Despite growing awareness of the issue, effective methods for their detection and removal from environments remain limited, highlighting the urgent need for innovative solutions. The ever-decreasing size of microplastic particles, with some reaching as small as nanometers, presents a formidable challenge for existing technologies to identify and remove them from the environment accurately. Silicon filters offer a promising solution for filtering out microplastics, because they do introduce contamination, maintaining the purity of samples during filtration processes. Additionally, silicon exhibits a Raman shift that minimally overlaps with the Raman spectra of common microplastics. This spectral separation facilitates clearer detection and identification of microplastics in Raman spectroscopy analyses, as it minimizes background interference from the filter material itself. However, the development and fabrication of such filters are costly and complex, primarily due to the reliance on photolithographic mask processes required to achieve the desired pore geometries.
For this purpose, our study focuses on an innovative laser-based approach to streamline the fabrication of silicon filters with precise pore geometries. The effectiveness of this method is demonstrated by the successful fabrication of a silicon filter with elongated 15-micrometer pores. Moreover, this study also explores a novel cascade filtration system incorporating elongated 15-micron holes and a 90 nm aluminum oxide (AlOx) filter. The design combines high throughput with precision, targeting microplastics across a broad size range. The elongated holes ensure effective pre-filtration by capturing larger particles, while the AlOx filters enhance selectivity for submicron debris. This approach offers a scalable solution for water treatment applications, advancing microplastic removal technologies.

4.07.P-Mo368 Co-Benefit or Antagonisms of a Reed Filter for Water Treatment and Biodiversity?
***Juliette Fabure**[1], Marine Landrieux[1], Giacomo Grassi[1], Laetitia Routet[2], Marjolaine Deschamps[1], Claire-Sophie Haudin[1], Jeremie Lebrun[3] and Isabelle Lamy[1], (1)University of Paris-Saclay, INRAE, AgroParisTech, UMR ECOSYS, France, (2)Water and Sanitation Technical Department, France, (3)University of Paris-Saclay, INRAE, UR HYCAR - Artemhys, France*
As part of the treatment of run-off water from the Paris western ring road, the City of Paris has installed an extensive filtration system in the Bois de Boulogne site (West of Paris woods). The aim of the system is to combine the need to clean up polluted water with the need to preserve biodiversity.
In addition to treating polluted water, particularly in terms of Trace Metal Elements (TME) and polycyclic aromatic hydrocarbons (PAH), our objective is to study the colonisation dynamics of the sandy substrate of the reed filter and the influence of changes in physico-chemical parameters on the filter ecology, and to verify the impact of treated water discharges on the receiving aquatic environment. For 2 years, we monitored changes in substrate properties (pH, organic matter, cation exchange capacity, etc.), levels of

TME and PAH contamination, enzymatic activities in the environment, and earthworm and enchytraeid populations (density, specific richness). At the same time, we caged gammarids, a model aquatic invertebrate, in the receiving river, upstream and downstream of the planted filter discharge, and measured sublethal biomarkers to characterise the impact of the filtration system on the receiving environment. As the filter plant evolved, and in particular as the sedimentation and reeds enriched the substrate with organic matter, an increase in the oligochaetes density and diversity was observed. The results show that the dynamics of planted filter colonisation are strongly linked to changes in the properties of the environment, in particular the level of organic matter. Although contamination levels are increasing, they remain relatively low and have no impact on the biological colonisation dynamics of the filter. On the other hand, discharges of treated water are beneficial to the receiving environment, firstly because contaminant levels are fairly low, and secondly because the treated water helps to improve some river parameters, particularly oxygen level. The planted filter system is therefore a water treatment system of ecological interest.
In the future, the long term monitoring of the chemical, physico-chemical and ecological dynamics in the filter will enable to assess the benefits or limitations of this type of water treatment system in terms of environmental quality and biodiversity.

4.07.P-Mo369 Simultaneous Partial Nitritation, Anammox and Denitrification Reactor: A Focus on Alkalinity Availability Under Mainstream Conditions

Paula Takeda[1]*, Elis Watanabe Nogueira*[1]*, Andre do Vale Borges*[1]*, Adrian Ferreiro*[2]*, Juan Manuel Garrido*[2] *and Marcia Helena Rissato Zamariolli Damianovic*[1]*, (1)University of São Paulo, Brazil, (2)University of Santiago de Compostela, Spain*
Simultaneous partial nitritation, anammox, and denitrification (SNAD) in a single-stage reactor has emerged as a feasible and sustainable approach for mainstream nitrogen removal. SNAD offers several advantages over conventional biological nitrogen removal (CBNR), such as reduced costs associated with aeration, sludge generation, and disposal. However, maintaining long-term stable SNAD operation remains challenging due to the simultaneous growth of different functional microorganisms. Municipal wastewater typically contains nitrogen concentrations of 1.8-4.3 mEq N L-1 and alkalinity levels between 1.5 4.0 mEq CaCO3 L-1. While CBNR processes generally consume alkalinity at a rate of 1.0 mEq CaCO? por mEq N removed, the role of alkalinity in SNAD processes is still not fully understood. This study aimed to evaluate alkalinity availability in a SNAD reactor fed with anaerobically pre-treated municipal wastewater (APMW). The bioreactor was operated over 90 days in three experimental phases: (I) SNAD start-up and granular biomass adaptation from synthetic wastewater to APMW; (II) addition of biocarriers to improve biomass retention; and (III) an increase in the hydraulic retention time from 8 to 12 hours. During phases I and II, ammonium removal rates reached approximately 46% and 61%, respectively, which primarily drove alkalinity consumption in the reactor by nitritation and anammox reaction. Additionally, denitrification likely contributed to alkalinity production, resulting in increased effluent concentrations of 9.5 mEq L-1 and 9.7 mEq L-1, respectively. In phase III, high and stable performance was observed for both organic matter (75% COD) and nitrogen (70% N) removal, along with alkalinity production of approximately 1.5 mEq L-1, or 0.8 mEq CaCO? por mEq N removed. This production rate helped regulate effluent pH, which ranged from 7.4 to 7.6, ensuring suitability for wastewater discharge in water bodies. Moreover, optimal mEq HCO?-/mEq NH??-N ratios reported for partial nitritation and anammox processes range from 0.2-0.9 and 1.2-3.5, respectively; in this study, stable SNAD performance was achieved at an approximate ratio of 3.7 mEq HCO?-/mEq NH??-N. Overall, these findings demonstrate that using APMW in a SNAD reactor provides adequate influent alkalinity for bioprocessing and results in suitable effluent alkalinity for subsequent wastewater disposal.

4.07.P-Mo370 Aqueous Phase Mitigation of Chemical Oxygen Demand in Wastewater using Adsorbents from *Delonix regia* Pod Husks

Emmanuel Onche[1]*, Sarah Doofan Adia*[2]*, Aka Joy Egwumah*[1]*, Stephen Kuleve*[1]*, Joseph Yande*[2] *and Raymond Wuana*[1]*, (1)Joseph Sarwuan Tarka University (Formerly Federal University of Agriculture, Makurdi), Nigeria, (2)Benue State University Makurdi, Nigeria*
The present study aimed to compare the adsorption efficiency of an adsorbent derived from agricultural waste, specifically *Delonix regia* pod husks, as the widespread use of commercial activated carbon is often limited by its high cost. The *Delonix regia* pod husks were ground into a fine powder using a mortar and

pestle. This powdered material was then sieved using a 0.25 mm mesh sieve and steeped overnight in a saturated ammonium chloride solution (NH_4Cl) for chemical activation. The resulting slurry was filtered and the filtrate was discarded. The residue was thoroughly washed with distilled water and subsequently sun-dried. Next, the activated material was divided into two portions. The first portion produced the chemically activated adsorbent, designated as ADR, while the second portion underwent pyrolysis in a muffle furnace (NEY M-525) at 350°C for 1.5 hours to yield the activated carbon, referred to as CDR. Both adsorbents, ADR and CDR, were utilized to treat wastewater, focusing on the removal of organic components responsible for the chemical oxygen demand (COD) in industrial wastewater. The adsorption process was assessed through batch adsorption experiments, measuring the amount of COD adsorbed (mg.g-1). Various factors were investigated, including adsorbent dosage, pH, contact time, and temperature. The optimal adsorbent dose was determined to be 2.5 g for both ADR and CDR, achieving removal rates of 64.21% and 66.48%, respectively. FTIR analysis indicated absorbance peaks at 2363 cm-1 and 2963 cm-1 for OH functional groups, and at 3226 cm-1 for NH2 groups, suggesting that the adsorbent CDR has a higher adsorption capacity than ADR. The equilibrium data for COD removal were found to fit both the Linearized Langmuir and Freundlich models well. This strong correlation between the experimental adsorption rate data indicates that these models could be effectively applied in design applications.
Keywords: Activated Delonix regia (ADR), Carbonized Delonix regia (CDR), Chemical Oxygen Demand (COD),Potential of Hydrogen (pH), Fourier Transform Infrared Spectroscopy(FTIR)

4.07.P-Mo371 Removing Chromium (VI) from Wastewater with Crosslinked Calciumphosphate/Chitosan/Gelatine Coated Polylactic Acid Pellets

***Michelle Reese*[1]*, Andreas Taubert*[1]*, Judtith Schicks*[2]*, Christina Gunter*[1] *and Jiyong Kim*[3]*, (1)University of Potsdam, Germany, (2)GFZ Potsdam, Germany, (3)Fraunhofer IAP, Germany*

Chromium (VI) [Cr(VI)] is, among others, toxic and carcinogenic. Nevertheless Cr(VI) compounds are still used in different industries such as tanning and chromium plating and can be found in soil and water around the factories in various concentrations. Chitosan/crosslinked chitosan can be used for the removal of Cr(VI) from wastewater. However the synthesis of crosslinked chitosan is often time consuming. In addition the data situation in the analytical field have so far been unsatisfactory, especially in regards to the possible reduction of Cr(VI) to Cr(III). However this information is crucial because Cr(III) is less dangerous than Cr(VI).

The current work is an extension to existing systems and focuses on calciumphosphate/crosslinked biopolymer-coated poly(lactic acid) pellets for the removal of chromate from aqueous solution, where the biopolymer is chitosan or gelatine. The best adsorption results were obtained by a crosslinked chitosan/gelatine material (99.6% removal in 24 h). All three materials were analyzed by scanning electron microscopy (SEM), energy-dispersive X-ray spectroscopy (EDX), X-ray photoelectron spectroscopy (XPS), UV-VIS spectroscopy, X-ray microprobe and inductively coupled plasma optical emission spectroscopy (ICP-OES). Microprobe and ICP-OES measurements point out the successful adsorption of chromium. A color change of all three materials to a a greenish tone suggested the reduction to Cr(III) and XPS and UV-VIS spectroscopy prove that Cr(VI) can be reduced by the material. Overall, the data suggest a possible application of chitosan materials in wastewater treatment where adsorption and Cr(VI) to Cr(III) reduction can be combined in one material.

All in all the results show that the addition of chitosan is crucial for the adsorption of Cr(VI). By adding gelatine the adhesion of the coating can be improved. Current challenges include upscaling of the synthesis and adsorption experiments, using real wastewater and substitution of glutaraldehyde by a biocompatible and biodegradable crosslinker.

4.07.P-Mo372 Mitigation of Hydrogen Sulfide Emissions and Corrosion in Wastewater Treatment Using Ferric Chloride Foam: A Comparative Study with $FeCl_3$ Mixing

Seung-Woo Jeong *and Rabin K.C., Kunsan National University, "Korea, Republic of"*

Hydrogen sulfide (H2S) emissions from wastewater sludge cause intense odors and severe corrosion in treatment facilities. While ferric chloride (FeCl3) mixing is a common strategy for reducing H2S emissions, its efficiency decreases at high concentrations. This study investigates the use of ferric chloride foam (FC-foam) as an alternative surface application method and compares its effectiveness with traditional FeCl3-sludge mixing.

Batch tests revealed that FC-foam reduced cumulative H2S emissions by 86.44%, significantly outperforming the 49.22% reduction achieved by FeCl3 mixing. In semi-continuous tests, FC-foam

application reduced H_2S concentrations by 91.40% (from 5125 ppm to 440.5 ppm), compared to a 71.38% reduction (from 5125 ppm to 1466.5 ppm) with $FeCl_3$ mixing. FC-foam mitigates H_2S emissions through two primary mechanisms: forming a stable 28-hour barrier that prevents H_2S release and leaching ferric chloride to react with sulfide ions on the sludge surface.
The study also evaluated the biodegradability and corrosion-inhibition properties of the AOS surfactant in FC-foam. Biodegradability tests confirmed near-complete degradation within 10 days, while corrosion tests demonstrated a 61.19% to 67.04% reduction in corrosion on carbon steel compared to $FeCl_3$ mixing. These findings suggest that FC-foam is a promising alternative for maintaining low H_2S concentrations (6-8 ppm) and mitigating corrosion, offering a simple yet effective solution that addresses the limitations of conventional $FeCl_3$ mixing in wastewater treatment.

4.07.P-Mo373 Effluent Reuse in Greenhouse Horticulture: Measures to Ensure Safe and Sufficient Irrigation Water

*Nienke E. Koeman[1], Astrid Reus[1], Patrick Smeets[1], Milou M.L. Dingemans[1,2], Carina Eisfeld[3], **Stefan Kools**[1] and Emile Cornelissen[1,4], (1)KWR Water Research Institute, Netherlands, (2)Institute for Risk Assessment Sciences, Utrecht University, Netherlands, (3)Stichting Control in Food & Flowers, Netherlands, (4) Ghent University, Netherlands*

Due to changing rainfall patterns, water supply in greenhouse horticulture is under pressure. While most growers currently rely on rainwater as the primary source for irrigation, this is generally insufficient to meet the needs of plants. As a result, growers often use supplementary sources, such as groundwater, which is a precious resource which faces future restrictions. Effluent from wastewater treatment plants, which can be treated to become suitable for irrigation, is increasingly considered as an irrigation source. However, growers are hesitant to adopt this solution without guarantee that the effluent is safe for human, animal, and plant health and the environment. Here, measures are presented to provide water with the required quality requirements to guarantee safe irrigation for the crops, employees, and consumers of the crops. They are included in a framework that entails water treatment, process monitoring, water quality monitoring and risk assessment.
As effluent quality can fluctuate over time it is important to implement treatment processes such as reverse osmosis combined with advanced oxidation. This treatment can remove many contaminants, although some may remain. A risk analysis, including a quantitative microbial risk assessment (QMRA), is required to meet EU regulations and address health risks. Findings suggest that additional treatment steps, such as ultraviolet (UV) or ozone disinfection, are necessary to ensure safe water for irrigation. Moreover, the current EU regulations do not address risks to plants, which are a significant concern for growers. While treatment processes like reverse osmosis and UV can reduce microbial contaminants, the acceptable levels of phytopathogens and their treatment remain unclear. As part of the chemical and ecological risk assessments, the use of bioassays is explored for testing the effects of specific contaminants on plant growth.
In conclusion, regulations and trade practices allow the use of treated effluent as an irrigation water source, and advanced treatment processes ensure a water quality that can mitigate microbial and chemical risks. Monitoring and verification systems are essential to ensure the continued safety and efficacy of effluent as irrigation water. In this way, safe effluent reuse in greenhouse horticulture can contribute to sustainable water use.

4.08 Antimicrobials and Antimicrobial Resistance in the Environment

4.08.T-01 Minimum Selective Concentrations of Antibiotics: A Resistance Cost-Based Approach Towards Representative Estimates

David Kneis[1]*, Magali de la Cruz Barron[1], Uli Klumper[1], Patrick Schroder[2], Kathi Westphal-Settele[2], Jens Schonfeld[3], Dirk Jungmann[1] and Thomas U. Berendonk[1], (1)TU Dresden, Institute of Hydrobiology, Germany, (2)Pharmaceuticals, German Environment Agency (UBA), Dessau-Rosslau, Germany, (3)German Environment Agency (UBA), Germany*

Selection for antibiotic resistance in bacteria is known to occur at drug concentrations far below therapeutic levels. At the same time, reports of elevated concentrations of antibiotics in contaminated environments call for the prediction of no effect concentrations (PNECs) and corresponding regulatory measures. The standard approach to the derivation of PNECs addressing selection for antibiotic resistance is centered around the minimum selective concentration (MSC). The latter is defined as the drug concentration where resistant and susceptible bacteria are subject to equal fitness. Competition assays provide straightforward means to determine the MSC for particular pairs of resistant and susceptible strains. However, in light of substantial inter- and intra-species diversity, the large number of resistance gene variants, their embedding in alternative genetic contexts, and the variability of environmental conditions, it is hardly feasible to derive truly representative MSC values through experiments. Consequently, attempts have been made to derive minimum values of the MSC from existing data for subsequent use as PNECs. The most prominent approach computes the PNEC as the lowest observed inhibitory concentration (lowest MIC) of any bacterial strain multiplied by an assessment factor of 1/10. Here, we demonstrate that the factor providing the link between MSC and MIC is equivalent to the cost of resistance. Specifically, the cost reflects a relative drop in the intrinsic growth rate associated with the resistance trait. Because the distribution of resistance costs can be estimated from existing data with reasonable accuracy, we propose to employ this information in the derivation of PNECs. Our results suggest that the current, most widely used approach (PNEC = lowest MIC * 1/10) is rather tolerant. In this contribution, we provide arguments for a more stringent approach considering, e.g., the very low costs of laterally transferable plasmid-borne resistance or the yet underexplored consequences of evolutionary cost reduction.

4.08.T-02 Antibiotics Residues in Irish Sediments
***Martin Sharkey**[1], William A. Stubbings[2], Stuart Harrad[2], Mark Healy[1], Shijie Wang[2], Jinxi Jin[2] and Marie Coggins[1], (1)University of Galway, Ireland, (2)University of Birmingham, United Kingdom*
This study assesses the concentrations of a range of antibiotics in riverine and transitional sediments in Ireland. A selection of 12 macrolide, fluoroquinolone, sulphonamide, and diaminopyrimidine antibiotics were quantified in 80 grab surficial sediment samples from around Ireland, selected to investigate areas of potentially higher pollution risk (agriculture, aquaculture, industrial emissions, and wastewater emission points) as well as isolated areas where there are no known pollution sources. Several of the macrolides and sulphonamides/trimethoprim were generally detected more frequently above limits of quantification (LoQ). Fluoroquinolones, while frequently detected above limits of detection (LoD), concentrations were mostly below method LOQs. The most prevalent antibiotic detected was clarithromycin, found at the highest mean concentration (6.65 ng/g) and detected in ~90 % of samples. Comparing levels of quantified antibiotics to levels reported internationally, Ireland is at the lower end for all quantified antibiotics. This is with the notable exception of clarithromycin, which is higher than levels found in comparable studies in Italy, Spain, France, and Argentina. Higher levels of total antibiotics (49.3 ± 24.7 ng/g) were found to be present immediately adjacent to wastewater emission points while moderate degrees of contamination (9.0 ± 9.7 ng/g) were also linked to wastewater, aquaculture, or agricultural pressures. Based on risk quotients calculated from available sediment PNECs taken from the NORMAN ecotoxicology database, clarithromycin was also the only compound to be present at concentrations indicative of a moderate degree of environmental risk, with most of the remaining falling below this threshold. Ciprofloxacin was ostensibly found to be of a high degree of environmental risk; however, this is based on only a single sample quantified above the LoQ. Overall, antibiotic sediment concentrations suggest a low ecotoxicological risk for most of the target antibiotics, although clarithromycin, ciprofloxacin, and sulfamethoxazole warrant further monitoring in sediments.

Disclaimer/Disclosure: This project is funded under the EPA Research Programme 2021-2030 (2021-HE-1056) and co-funded by the Department of Agriculture, Food and the Marine. The EPA Research Programme is a Government of Ireland Initiative funded by the Department of Environment, Climate, and Communications.

4.08.T-03 Evaluation of Antibiotic Mixtures through the SELECT Assay and Risk Assessment of Antibiotics in the World's Rivers
***Alejandra Bouzas Monroy**[1], John Wilkinson[2], Ville Friman[3] and Alistair Boxall[4], (1)University of York, York, United Kingdom, (2)Environment and Geography, University of York, United Kingdom, (3)University of Helsinki, Finland, (4)University of York, United Kingdom*
Due to the extensive use of antimicrobials throughout the human, veterinary and agricultural sectors, antimicrobial resistance has become one of the greatest concerns to human health across the world. Though selection for antimicrobial resistance (AMR) has been proven to occur at environmental

concentrations of antimicrobials, no standardized experimental method has been designed to determine this. In the last couple of years, various predicted no effect concentrations for AMR have been suggested. However, selection for resistance some PNECs may not protect against selection and do not consider mixture effects. Therefore, this study aimed to: 1) evaluate mixtures of antibiotics using the SELECT assay and qPCR, 2) assess the potential risk of antibiotic exposure worldwide through the generation of hazard quotients, and 3) compare different sets of PNECs proposed in recent years based on various endpoints. No Observed Effect Concentrations (NOECs) were previously determined for fifteen antibiotics using the SELECT assay. A mixture of the single compound NOEC for five WWTP was then evaluated using the SELECT method. Hazard quotients were calculated using the measured concentrations of antibiotics detected by Wilkinson et al. (2022) across the world and various Predicted No Effect Concentrations (PNECs). The different PNECs used were those determined by Bengtsson-Palme and Larsson (2016) (PNECMIC), the AMRIA (PNECAMRIA) and the SELECT assay (PNECsSELECT). The mixture of NOECs for each WWTP presented a lower NOEC than the mixture of the single compound NOECs. One in seven river sites globally presented concentrations where antibiotics may be expected to be causing some effects on bacteria. Overall, the findings in this study indicate that even at concentrations where no effect is expected for antibiotics as single compounds, the combination of these may cause selective pressure on bacterial communities and may be increasing the relative abundance of certain resistance genes. Additionally, this study showed the potential hazards of antibiotics in surface waters across different continents, providing us a first glimpse into the potential impacts of AMR globally.

4.08.T-04 Flow of AMR Drivers Through the Farm Environment

*Felicity C.T. Elder[1], Tony Buckley[2], Katie McDermott[2] and **Laura Carter**[3], (1)School of Geography, University of Leeds, United Kingdom, (2)University of Leeds, United Kingdom, (3)School of Geography, University of Leeds, United Kingdom*

A circular economy between agriculture and organic waste streams can recycle essential resources for farming through the recovery of water, biomass, and nutrients from sanitation waste solids, effluents, and livestock manure at scale. However, one of the most challenging barriers to safely operating a sanitation-agriculture circular economy is the widespread occurrence of antibiotics and other antimicrobial agents in manure and sanitation waste and the potential role this plays in the development of antimicrobial resistance (AMR). The potential environmental and health risks of the transmission of antimicrobial molecules and ARGs in farm settings are currently unknown. To address this knowledge gap, laboratory models were used to track antibiotic resistant genes and antimicrobial residues at a bench top scale to reveal novel insights into where biological and chemical contaminants aggregate following antibiotic administration to livestock and manure reuse. Specifically the fate of a tagged blaCTX-M antibiotic resistant gene alongside amoxicillin and oxytetracycline antibiotics were tracked across a model gut soil plant continuum to help identify contaminant hotspots and thus identify where interventions need to be made. The fate of the tagged ARG and antibiotics was monitored in the porcine gut model over 4 weeks, after which the slurry was stored and then applied to soil, which was used to grow radish (*Raphanus sativus*). Quantification of ARG and chemical fate was achieved using Liquid Chromatography Mass Spectrometry and real-time PCR. Our results showed the dissemination and longevity of AMR drivers in slurry-soil-plant systems. With and without antibiotic pressure (i.e. no oxytetracycline or amoxicillin) the tagged ARG was quantified in the slurry pre-soil application and in the soil on day 0 (29.58 32.88 copies per 16S rDNA). Antibiotics were detected in the slurry (<372352 ng/g), slurry amended soil (<84.35 ng/g) and radish (<436.1 ng/g) demonstrating the persistence of antibiotics and ability to bioaccummulate in crops. The soil appears to be acting as a barrier to ARG accumulation in crops as blaCTX-M antibiotic resistant gene abundance in the radish was below quantifiable levels. Overall, our work therefore confirms that AMR constituents present in farm waste streams can accumulate in agricultural systems with the potential to crops, demonstrating pathways for human exposure via the consumption of contaminated produce.

4.08.T-05 Implementing Environmental Criteria for Antibiotics Production - Antibiotic Occurrence in Wastewater, Runoff and Impacted Water Bodies

***Ursula Karges**[1], Tim aus der Beek[2], Pia Springmann[1], Arne Hein[3], Daniela Gildemeister[3] and Ute Kuhnen[3], (1)IWW Water Research Institute, Germany, (2)IWW Water Research Insitute, Germany, (3)UBA (German Environment Agency), Germany*

Antibiotic resistance is increasingly jeopardising the effectiveness of prevention and medical treatment of an increasing number of infectious diseases and is causing a high number of premature deaths worldwide.

By now, it is widely recognised that the release of antibiotics into the environment via production wastewater discharged from the pharmaceutical industry constitutes an important factor. Evidently, tackling such point sources through appropriate treatment of production wastewater would be a decisive step towards achieving a substantial reduction in antibiotic pollution and consequently in a reduction of occurrences of resistant pathogens. The here presented study addresses the overall feasibility of implementing maximum permitted API concentrations in production wastewater and how to verify compliance. Wastewater from 19 production sites from Europe, India and China has been investigated. The sites selected previously agreed to comply with the PNEC values for certain antibiotics in their wastewater and to permit independent inspections. In addition, wherever possible, supplementary environmental investigations were conducted in water bodies adjacent to the production sites.
Over 27 different antibiotics have been detected, some of them repeatedly and at several sampling locations. Antibiotic concentrations exceeding PNEC limits were found at ten production sites - both in wastewater samples and in affected environmental samples. Maximum environmental concentrations ranged from 0.1 µg/l up to 18.5 mg/l, wastewater concentrations from 0.1 µg/L to 22.5 µg/L. In the total number of environmental water samples analysed, more than 60% of antibiotic concentrations exceeded the ecotoxicological PNEC value, whereas no reliable, scientifically derived effect threshold was available for other antibiotics in these samples.
The results of our study confirm and quantify that wastewater from pharmaceutical production sites, as well as surface runoff and thus the general handling of active substances at these sites, contribute significantly to high concentrations of antibiotics in the environment and thus to the potential emergence of antibiotic resistance. Moreover, in view of the current intention to regulate the emissions of antimicrobial substances via the environmental risk assessment for human pharmaceuticals, it should be borne in mind that an effective system for verifying the values or explanations provided by the companies is required.

4.08.P Antimicrobials and Antimicrobial Resistance in the Environment

4.08.P-Tu341 Monitoring Antibiotics and Antimicrobial Resistance in an Urban Waterway

Shubham Anurag *[1], Ravikrishna Raghunathan[1] and Indumathi M. Nambi[2], (1)Department of Chemical Engineering, Indian Institute of Technology Madras, India, (2)Division of Environmental and Water Resources, Department of Civil Engineering, Indian Institute of Technology Madras, India*

Antimicrobial resistance (AMR), often termed the "Silent Pandemic," poses a significant global health challenge, with environmental reservoirs playing a crucial role in the evolution and transmission of resistance. Urban waterways like the Buckingham Canal (BKM) in Chennai, Tamil Nadu, India which receives 60% of untreated sewage and acts as a conduit for stormwater and various pollutants, may serve as potential hotspots for AMR proliferation.
This study investigated the presence of antibiotics, antibiotic-resistant bacteria (ARBs), and resistance genes (ARGs) in BKM, assessed their temporal and spatial variations, and explored correlations to understand AMR contributing factors. Water samples were collected at different intervals (June 2022, April 2023, June 2023, and January 2024), and sediment samples were obtained in April and June 2023 across approximately a 45-km stretch of the canal. Antibiotic concentrations were quantified via liquid chromatography-tandem mass spectrometry (LC-MS/MS) and bacterial counts by colony-forming units (CFU). Antimicrobial susceptibility testing (AST) and the Multiple Antibiotic Resistance (MAR) index measured resistance patterns in *Escherichia coli*, a fecal contamination indicator. Metagenomic sequencing identified ARGs and ARBs. Correlations among physicochemical parameters, antibiotic concentrations, and AMR indicators established a baseline understanding.
Results showed higher *E. coli* counts in water than in sediment due to sewage discharge. MAR indices exceeded 0.2 at all locations, indicating high-risk contamination. The wet season had increased CFU counts. Antibiotic concentrations exceeded 30,000?ng/L, even at less polluted sites like KVM and MBR, suggesting unexpected sources. Correlations between antibiotic concentrations and AMR indicators indicated a complex relationship influencing AMR development.
The insights gained will inform future studies on the exchange and transport of AMR elements between environmental compartments (water, sediment, air), which is essential for identifying sources, high-risk environments, and dissemination pathways to guide the development of predictive models aimed at mitigating the spread of AMR, contributing to global efforts to safeguard public health and ecosystems.

4.08.P-Tu342 Multi-Contamination and Antimicrobial Resistance Genes in a Stretch of River Danube

Paola Grenni[1]*, Ludovica Rolando*[1]*, Alessandra Narciso*[1]*, Chiara De Carolis*[1]*, Michela Pirredda*[2]*, Luisa Patrolecco*[3]*, Jasmin Rauseo*[3]*, Francesca Spataro*[3]*, Katalin Monostory*[4]*, Bernadet Khayer*[5]*, Karoly Tor*[5]*, Marta Vargha*[5] *and Anna Barra Caracciolo*[6]*, (1)Water Research Institute, National Research Council, Italy, (2)Departamento de Biotecnología-Biología Vegetal, ETSIAAB. Universidad Politecnica de Madrid, Spain, (3)Institute of Polar Sciences, National Research Council (ISP-CNR), Italy, (4)Institute of Molecular Life Sciences, HUN-REN Research Centre for Natural Sciences, Budapest - Hungary, Hungary, (5)National Public Health and Pharmaceutical Center (NNGYK), Budapest Hungary, Hungary, (6)Water Research Institute-National Research Council, Italy*

Legacy and emerging pollutants are present as a mixture in river waters. Antibiotics (ABs) and antimicrobial resistance genes (ARGs) have been arising particular concern for the possible effects on ecosystems and human health, in accordance with the One-Health concept. WWTPs are recognized as the main source of river contamination for ABs and ARGs. These contaminants can cause disappearance and inhibition of some microbial species involved in key ecosystem functions promoting AB resistance spread among natural microbial populations and from them to humans, plants and animals by using river water for drinkable purposes and/or reclaimed water. The antibiotic resistance phenomenon seems linked not only to AB presence, but also to co-selection on bacteria by other pollutants (e.g. biocides, heavy metals) commonly found in surface water.

A river Danube stretch has been studying for 2 years (2023 and 2024) and was sampled during two consecutive seasons (spring and autumn) in selected site inside and outside Budapest city (1. before the city, close to the bank filtration water supplies; 2. inside Budapest city and downstream from a WWTP; 3. after the city, downstream another WWTP). Antibiotics (amoxicillin, ciprofloxacin, enrofloxacin, erythromycin, sulfamethoxazole and its main metabolite N4-smx) and several other contaminants (metals, antipyretics, anti-inflammatories, hormones, anticonvulsants, insect repellents, stimulants, disinfectants) were analysed. The resistance genes for sulphonamides (sul1 and sul2), the plasmid-mediated quinolone resistance genes (aac-(6')-Ib-cr, qnrS and qepA) and the mobile genetic element intI1 were also searched for. Moreover, microbial abundance (direct counts), main pathogens (indicators of human footprint and water quality), including *Clostridium perfringens* (potential hosts of ARGs) and possible estrogenic effects (Yeast Estrogenic Screen, YES), were measured.

Overall results showed diffuse pharmaceutical residual concentrations (e.g. antibiotics, antipyretics and anti-inflammatories) in all sampling points, with seasonal differences. The most polluted point was that inside the city. The estrogenic effects also showed this point as the most polluted one.

Sulfamethoxazole and ciprofloxacin were the antibiotics found at the highest concentrations in all three sampling points. ARGs were always found, with the highest values for sulfonamides; however their presence was not directly correlated to antibiotic concentrations

4.08.P-Tu343 Monitoring Antibiotic Resistance from Hospital Effluent and Wastewater Treatment Plant to Surface Waters

Judit Kalman *and Yolanda Valcarcel Rivera, Rey Juan Carlos University, Spain*

Hospitals and wastewater treatment plants (WWTP) are significant sources of antibiotic resistance, introducing resistant bacteria and genes into surrounding water systems. The environment plays a crucial role in the spread of antibiotic resistance and is a key focus of the One Health approach to tackle this global issue. To trace the route of antibiotics and antibiotic resistance genes (ARGs) from hospital sources through wastewater treatment processes and into the environment, a study was conducted in a southern region of Madrid, Spain. With approximately 350 beds, the public hospital provides healthcare services to an estimated population of 170,000. The nearby WWTP, which serves a population of over 200,000 employs secondary and tertiary treatment processes to ensure water quality prior to discharge. These processes play a critical role in mitigating the release of antibiotics and ARGs into the environment.

Two sampling campaigns were carried out in early spring and summer, during which water samples were collected from hospital effluent, WWTP influent and effluent, a downstream location, and a nearby river into which the stream flows. Eight antibiotics, including macrolides, sulfonamides, fluoroquinolones, penicillins, and tetracyclines, were analyzed using liquid chromatography coupled with mass spectrometry. Six ARGs, the class 1 integron-integrase, and 16S rRNA gene abundance were quantified by real-time PCR.

All ARGs were detected, with gene copy numbers generally decreasing from the hospital effluent to the river.

The study will explore potential differences in antibiotic and ARG levels between early spring and summer to identify possible relationships between climatic environmental conditions and the increased frequency of resistance in hospital effluent, WWTP influent and effluent, and receiving water bodies. Additionally, the performance of the WWTP in removing antibiotics and ARGs will be assessed to better understand the role of the WWTP in mitigating the spread of antibiotic resistance to the surrounding environment.

Disclaimer/Disclosure: Funding: Program for the Promotion and Development of Research and Innovation of the URJC (Bridge Projects).

4.08.P-Tu344 Dissemination of Antimicrobial Resistance Contaminants from On-Site Sewage Facilities and Potential Mitigation Strategies

Valentina Ugolini[1]*, Harold Flores Quintana*[1]*, Jessica Subirats Medina*[2]*, Paul Loffler*[3]*, Lutz Ahrens*[1]*, Elin Ulinder*[4]*, Pia Rapp*[5]*, Catarina Dunge*[5]*, Alberto Celma*[1]*, Gabriel Sigmund*[6] *and Foon Yin Lai*[7]*, (1)Department of Aquatic Sciences and Assessment, Swedish University of Agricultural Sciences (SLU), Sweden, (2)IDAEA-CSIC, Spain, (3)Aquatic Sciences and Assessment, Swedish University of Agricultural Sciences (SLU), Sweden, (4)RISE Research Institutes of Sweden, Sweden, (5)Oskarshamn Municipality, Sweden, (6)EDGE, Wageningen University and Research (WUR), Wageningen, Netherlands, (7)Swedish University of Agricultural Sciences (SLU), Sweden*

Domestic wastewater is a reservoir of contaminants related to antimicrobial resistance (AMR), including antimicrobial chemicals and AMR-related genes (e.g., antibiotic resistance genes (ARG)). On-site sewage facilities (OSSF) are used for decentralized wastewater treatment in areas without access to centralized sewage systems. In Sweden, OSSF treat ~13% of domestic wastewater. Occurrence of several organic chemicals in OSSF and receiving waters has been reported, although a substantial gap remains in understanding the role of OSSF in the proliferation and dissemination of AMR contaminants into the environment. This study aims to investigate the occurrence and dissemination of AMR contaminants in OSSF and its associated receiving groundwater, as well as the potential of biochar as a sustainable mitigation material. Wastewater and groundwater samples were collected during four different months from an OSSF, comprising a septic tank, aerated pond, and infiltration site, as well as a nearby centralized wastewater (WWTP) and drinking water treatment plants. UHPLC-MS/MS was used for chemical analysis, and high-throughput qPCR was used to quantify AMR-related genes. AMR selection risk and potential human ARG intake were also evaluated. Lab-scale experiments to assess the potential of biochar for removal of AMR contaminants were performed. Antimicrobial chemicals were less frequently found in OSSF compared to WWTP, attributed to sporadic consumption and lack of hospital or industrial discharges. Fluconazole was consistently detected in receiving groundwater but below AMR selection thresholds. Ciprofloxacin and fluconazole presented high AMR selection risk in OSSF wastewater. While septic tanks and aerated ponds removed many AMR-related genes, some (e.g., IncP_oriT, sul1) exhibited higher abundance in post-treatment. Clinically relevant ARG (e.g., blaCTX-M) were enriched in groundwater downstream of OSSF and occasionally also in a downstream private well. Biochar with high specific surface area effectively removed chemical contaminants in lab-scale experiments, while AMR-related genes were better retained with lower specific surface area, although with gene-specific variation. These findings underscore OSSF as contributors to AMR dissemination, necessitating better monitoring and regulation. Biochar may be a viable, sustainable, implementable mitigation strategy for the studied OSSF.

4.08.P-Tu345 Tracking Antimicrobial Resistance in Hyderabad's Musi River: Identifying Simple Markers for Wastewater-Driven AMR Pollution

Vikas Sonkar*, Indian Institute of Technology Hyderabad (IITH), India*

Antimicrobial resistance (AMR) is a silent pandemic that can be transmitted, spread and evolve in the environment. Numerous studies have been performed on waterborne AMR spread, but few have characterised the prevalence, sources, and transport of AMR in an Indian river catchment in adequate detail to inform mathematical modelling and exposure risk assessments.

Here we quantified taxonomic and AMR genes (ARGs), sensitive and AMR culturable bacteria (ARBs), and water quality conditions in water and sediment samples at ten locations along the Musi River (153 km. stretch) through Hyderabad, a city renowned for antimicrobial manufacturing, to develop a hydraulic model for AMR spread the catchment.

In the dry season, absolute water column ARG and ARB abundances increased rapidly upon entering into the city, then declined downstream, whereas the increase and decline of AMR levels was more gradual in the wet season. Clustering and ordination showed that the river consisted of three stretches in terms of

AMR: upstream, city, and downstream. Most water quality and AMR indicators differed significantly between stretches and seasons ($p < 0.05$; PERMANOVA), although the relative distribution of ARGs between sediment and water column samples differed in the dry and wet seasons. Linear Discriminant Analysis showed that some water quality parameters, such as lower dissolved oxygen and elevated total nitrogen, can distinguish between AMR-polluted and less-polluted sites and might be good AMR proxies in river monitoring. Modelling showed that between 60 and 80% of water in the flowing river was untreated wastewater, suggesting wastewater releases dominate AMR in the river, not manufacturing sources.
The study proposes using DO and TN measurements as cost-effective proxies for wastewater pollution and AMR contamination in resource-limited settings, offering a practical alternative to qPCR-based monitoring. Also this work here highlights the urgent need for improved municipal wastewater management and treatment to make rivers like the Musi safer for use, such as irrigation, reducing AMR exposures across wider environments.

Disclaimer/Disclosure: This work was part of the project AMRflows: antimicrobials and resistance from manufacturing flows to people: joined up experiments, mathematical modelling and risk analysis supported by the Department of Biotechnology (DBT) in India (Computer No. 8981 || BT/IN/Indo-UK/AMR-Env/03/ST/2020-21 || AMRFlows) and the Natural Environment Research Council (NERC) in the UK (NE/T013222/1).

4.08.P-Tu346 Antibiotic Resistance in *Lactococcus garvieae* in Italy: Temporal Dynamics and Geographic Patterns

Paolo Pastorino*, Silvia Colussi, Fabio Bondavalli, Giuseppe Esposito, Elena Bozzetta and Marino Prearo, The Veterinary Medical Research Institute for Piedmont, Italy*

Piscine lactococcosis is a significant bacterial disease in aquaculture, particularly affecting rainbow trout (*Oncorhynchus mykiss*), and leads to considerable economic losses worldwide. The increasing antibiotic resistance in *Lactococcus garvieae* poses a growing challenge, reducing treatment efficacy and necessitating the monitoring of resistance patterns over time. This study analyzed 62 *L. garvieae* strains isolated in Italy between 1991 and 2021 during lactococcosis outbreaks in rainbow trout to evaluate temporal trends and explore geographical differences in resistance patterns between two river basins with documented histories of the disease.
Antibiotic susceptibility testing was conducted using the Kirby-Bauer disk diffusion method for the following antibiotics: amoxicillin, ampicillin, erythromycin, enrofloxacin, florfenicol, gentamicin, kanamycin, penicillin, spiramycin, streptomycin, oxytetracycline, tetracycline, and thiamphenicol. Inhibition zone diameters were classified as susceptible, intermediate, or resistant according to the Clinical and Laboratory Standards Institute (CLSI) guidelines for aquatic animal pathogens. These categories were converted into semi-quantitative values for statistical analysis. Temporal trends (1991 1999, 2000 2010, 2011 2019, and 2020 2021) were assessed using Principal Component Analysis (PCA), while cluster PCA was applied to identify differences between strains from trout farms in the Ticino and Sile river basins. Statistical analyses were performed using R software. The results revealed notable resistance to aminoglycosides, including kanamycin, spiramycin, streptomycin, and gentamicin. Temporal PCA indicated an almost consistent resistance trend over time, though the ellipse for 2020 2021 deviated slightly, reflecting greater variability. Cluster PCA showed overlapping resistance patterns between strains from the two river basins, suggesting similar trends in antibiotic resistance. The observed resistance aligns with global reports of increasing aminoglycoside resistance among Gram-positive cocci. The observed trends highlight the need for enhanced antibiotic stewardship and the implementation of alternative strategies, such as vaccination, and improved farm biosecurity. Additionally, breeding programs focused on enhancing the genetic resistance of rainbow trout to diseases like lactococcosis could play a pivotal role in mitigating the impact of bacterial infections.

4.08.P-Tu347 Speciation/Characterisation of Chemical of Concern in Livestock Farming Systems

***Tolulope Lawrence**[1], Ana Castro-Castellon[2], Sydney Enns[2], Penny Johnes[2] and Barbara Kasprzyk-Hordern[1], (1)University of Bath, United Kingdom, (2)University of Bristol, United Kingdom*

Research on the impact of chemicals of concern (CoCs) like pharmaceuticals, antibiotics, pesticides, and sewage pollutants on UK freshwater quality has increased. However, livestock-derived organic matter (LDOM), which includes manure, slurry, urine, and dung, which is an equally important driver of change in freshwater quality has received insufficient attention. LDOM acts as a reservoir for CoCs from

veterinary treatments, pesticides, feed additives, and excreta management. These CoCs can persist in the environment, affecting the ecosystem and public health. There is significant knowledge gaps regarding the chemical and ecotoxicological impacts of livestock excreta, influenced by livestock type, production methods, management practices, and climate change. Livestock farming in the UK involved approximately 9.65 million cattle, 32.7 million sheep, 5.15 million pigs, and 183 million poultry in 2020. Cattle and sheep farming is predominantly located in the wetter northern and western regions, utilizing 10 million hectares of grassland, which accounts for 57% of the UK's agricultural land. It has also been reported that over 80% of oestrogen in UK rivers are from livestock production, with cattle excreting oestrogen an order of magnitude higher than humans. This study focus on 198 CoCs quantified in collected livestock excreta (farm manure, dung, slurries, and urine) from six UK cattle and sheep farms using ultra-performance liquid chromatography tandem mass spectrometry which forms part of a bigger study to understand the impact of sheep and cattle farming on UK freshwater quality under different environmental conditions..
This study identified the prevalence of antitubercular agents (isoniazid and isonicotinic acid) and macrolides (clarithromycin N-desmethyl, clarithromycin, erythromycin, and erythromycin N-desmethyl) among other antibiotic class in farm manure, dung, of sheep, dairy and beef cattle and slurries of cattle, while in the urine of the mentioned livestock, macrolides were prevalent. The detected antibiotics can cause antimicrobial resistance development, influence freshwater biota responses and pose a risk to human health through the food chain. This study reveals the range of CoCs released to the UK environment by livestock farming and provides some of the essential data required to support new, focused management and policy for livestock farming and UK freshwaters, and to inform the management of veterinary medicines in livestock husbandry.

4.08.P-Tu348 Manipulating the Antimicrobial Resistance Profile of Poultry Litter and Investigating the Effect on Microbial Community Composition and the Degradation of Trimethoprim

Bethany Adams[1]*, Laura Carter*[2]*, Paul Kay*[2]*, Chris Sinclair*[3]*, Philip Rooney*[4] *and Edward Haynes*[4]*,*
(1)University of Leeds, United Kingdom, (2)School of Geography, University of Leeds, United Kingdom, (3)Bayer S.A., São Paulo, Brazil, (4)Fera Science Ltd., United Kingdom

The current environmental risk assessment for antimicrobials used for the treatment of poultry does not take into account their potential contribution to the development and spread of antimicrobial resistance (AMR). Research on the emergence of AMR in poultry scenarios is limited, and existing studies have not explored how resistance affects the persistence of antimicrobials in poultry litter. This experiment aims to investigate how the microbial community and resistance profile varies across different poultry farms and how the resistance profile of the microbial community in the litter influences the persistence of the commonly used antibiotic trimethoprim. In order to address the first objective of this study, the microbial community profile and bacterial and fungal diversity of three different litters from three different farms was investigated using 16S and ITS metabarcoding. The AMR profiles of each of the litters from the different farms were tested using an agar well diffusion method for antibiotic susceptibility testing. The experiment conducted to address the second objective of this study included three sample groups: one group of litters inoculated with bacteria with known resistance to trimethoprim, another with bacteria with known susceptibility to trimethoprim and a control group with no additional bacterial inoculation. All samples were dosed with trimethoprim at 10 µg/g and a degradation study was carried out over 90 days in line with the guidance published by the European Medicines Agency in 2011 and OECD320 (where appropriate). The hypothesis of this experiment was that the degradation of trimethoprim will be slower in the samples inoculated with resistant bacteria and quicker in the samples inoculated with susceptible bacteria. Initial results from this study revealed that there were statistically significant differences ($p < 0.05$) between the alpha and beta diversity of the three litters from the different farms. Initial results from the antibiotic susceptibility testing revealed differences in the zones of clearance and levels of resistance between farms. The findings from this study will improve our understanding of the role of antibiotic resistant bacteria in the persistence of antimicrobials in the environment.

Disclaimer/Disclosure: The authors would like to thank the NERC Panorama DTP and Fera Science Ltd for funding this project.

4.08.P-Tu349 Antimicrobial Resistance Profiles of *Lactococcus garvieae* and *L. petauri* Isolated from Cultured Rainbow Trout in Türkiye, Italy, Spain and Greece

Paolo Pastorino[1]*, Rafet Cagri Ozturk*[2]*, Fabio Bondavalli*[1]*, Silvia Colussi*[1]*, Ana Isabel Vela*[3]*,*
Charalampos Kotzamanidis[4]*, Donatella Volpatti*[5]*, Lucio Fariano*[6]*, Ilhan Altinok*[2] *and Marino Prearo*[1]*,*
(1)The Veterinary Medical Research Institute for Piedmont, Italy, (2)Department of Fisheries Technology

Engineering, Karadeniz Technical University, Turkiye, (3)VISAVET and Department of Animal Health, Universidad Complutense de Madrid, Spain, (4)Veterinary Research Institute, Greece, (5)Department of Agricultural, Food, Environmental and Animal Sciences (DI4A), University of Udine, Italy, (6)Azienda Agricola Canali Cavour, Italy
Lactococcus garvieae and *L. petauri* are etiological agents of fish lactococcosis, causing severe losses in trout aquaculture, especially at elevated water temperatures. As there are no established zone diameters or minimum inhibitory concentration (MIC) breakpoints for these bacteria, classifying *Lactococcus* spp. as resistant or susceptible to antimicrobials remains challenging. Determining epidemiological cutoff values (ECVs) is critical for assessing antimicrobial resistance and distinguishing wild-type (WT) isolates (with no detectable resistance) from non-wild-type (NWT) isolates (with resistance), which are less responsive to antimicrobial therapy.
In this study, ECVs for 14 antimicrobials were established using *L. garvieae* (n = 32) and *L. petauri* (n = 78) isolates collected from rainbow trout farms across Türkiye, Spain, Italy, and Greece during lactococcosis outbreaks from 2003-2022. The study aimed to investigate and compare (i) ECV calculated using two different approaches, (ii) genetic antibiotic resistance, and (iii) the presence of gene cassettes and capsule gene clusters. The ECOFFinder and normalized resistance interpretation (NRI) approaches were used to calculate the provisional ECVs. An evaluation of gene cassettes, capsule gene clusters, and the presence of fourteen antibiotic resistance genes (ARGs) that encode resistance against seven antimicrobial agents, was conducted.
The ECVs ranged from 1.25 ?g mL?1 (amoxicillin) to 80.25 ?g mL?1 (streptomycin). The WT and NWT isolate percentages differed between methods, with ECOFFinder generally yielding higher WT percentages. ARGs for tetracycline (tetA), ?-lactamase (blaSHV, blaTEM, blaOXA), amphenicol (floR), and macrolide (ermA) resistance were detected in <10% of isolates, while those for quinolones (gyrA and qnrA) and aminoglycosides (strB) were most prevalent. The presence of Class 1 and Class 2 integron cassette regions was noted in 40.9% and 33.6% of isolates, respectively, with 9.1% containing both. None of the isolates tested positive for capsule gene clusters.
Significant but weak correlations were observed between and among ARGs and MIC distributions of antibiotics. These findings facilitate the classification of WT and NWT isolates and contribute to improved surveillance of antimicrobial susceptibility patterns in aquaculture pathogens.

Disclaimer/Disclosure: This study was funded by SUPERTROUT Project (20E03).

4.08.P-Tu350 In-Vitro Analysis of Environmental Factors - Induced Responses in Multidrug-Resistant *Escherichia coli* Strains

Maria Rosa Loffredo[1]*, Ifra Ferheen*[2]*, Chiara Poletti*[3] *and Stefania Marcheggiani*[1]*, (1)Istituto Superiore di Sanit, Environment and Health Department, Ecosystem and Health Unit, Italy, (2)Istituto Superiore di Sanit, Environment and Health Department, Ecosystem and Health Unit, Pakistan, (3)Istituto Superiore di Sanit, Environment and Health Department, Ecosystem and Health Unit & School of Biosciences and Veterinary Medicine, University of Camerino, Italy*
Climate changes can influence pathogenic bacteria directly by affecting their life cycles or indirectly by impacting their habitats and environments. Global temperature, precipitation, and humidity increase affect their transmission and distribution. Environmental stresses like pH, salinity, or temperature may also affect bacterial growth, replication, and physiological fitness, diving evolutionary trend-offs. One example is acquiring or losing antibiotic resistance from chemical residuals spread onto the environment. Rising antibiotic levels from anthropogenic activities and global temperature shifts highlight the need to understand how environmental factors influence bacterial survival and antimicrobial resistance. This study performed in the context of the European BlueAdapt project (https://blueadapt.eu/) aims to investigate the effects of environmental parameters, temperature and salinity, on antibiotic-resistance bacteria such as extended-spectrum beta-lactamases (ESBLs) *E. coli* isolated in our laboratory from the aquatic plastisphere community compared to reference *E. coli* ATCC 25922 strain. To simulate the change in bacterial growth due to the effect of climatic change, *E. coli* strains were incubated in a mesocosm model using media mimicking different salinities. To reflect the bathing water classification two initial inocula of *E. coli*, i.e., 102 CFU/100 mL and 105 CFU/ 100mL, were used and the bacterial growth was assessed daily after by CFU counting in different agar media after incubation at 25°C and 37°C. Data conducted on non-selective culture medium, i.e., Muller Hinton agar, showed that temperature did not markedly affect bacterial survival of both *E. coli* strains when grown in nutrient media. Conversely, a rapid decrease in

colony numbers was observed in media with a significantly higher salinity. Interestingly, the results obtained on selective culture medium, i.e., Tryptone Bile X-GLUC agar, showed that high temperature significantly affected the *E. coli* ATCC growth in saline buffers. In contrast, the ESBL-*E. coli* growth did not appear to be affected by synergic effect temperature-salinity showing a better adaptation to climate-induces changes. These findings highlight the intricate interplay between environmental factors in AMR survival and growth dynamics. Understanding these interactions is crucial for predicting the impacts of climatic changes on bacterial viability and antimicrobial resistance, especially in aquatic ecosystems.

4.08.P-Tu351 A Mesocosm Study to Assess the Effects of Benzalkonium Chloride on Biofilm, Phytoplankton, and Zooplankton

*Claire Estey[1], **Karen A. Kidd**[1], Jose Luis Rodriguez Gil[2], Lauren Timlick[2] and Michael Paterson[2], (1)McMaster University, Canada, (2)IISD-ELA, Canada*

Benzalkonium chloride (BAC) is a potent antimicrobial commonly used as the main ingredient in disinfectants and sanitizers, including those approved for use against COVID-19. Consequently, BAC use has increased globally in industrial, clinical, and household settings since the onset of the pandemic. This widespread usage has led to the continuous discharge of BACs into surface waters primarily via wastewater treatment plant effluents. Little is known about the effects of chronic BAC exposure on aquatic biota, particularly lower-trophic-level organisms such as biofilm, phytoplankton, and zooplankton. In the summer of 2023, an eleven-week mesocosm study was conducted at the International Institute for Sustainable Development Experimental Lakes Area (IISD-ELA) in northwestern Ontario, Canada, to assess the effects of BACs using five nominal concentrations (20, 112, 632, 3556, and 20 000 ng/L) and controls. Strips were deployed in the water column of each mesocosm to colonize with biofilm and sampled for chlorophyll a and ash-free dry mass. Integrated water samples were taken for BACs, nutrients, chlorophyll a and phytoplankton community assemblage. Zooplankton samples were collected and preserved at two- to three-week intervals and were identified to species and life stage for abundance and diversity analyses. Preliminary analyses indicate a decrease in biofilm chlorophyll a with increasing BAC concentration, but little effect on phytoplankton chlorophyll a or zooplankton abundance. Across all mesocosms, zooplankton communities were dominated by the cladoceran *Bosmina* spp., while the copepod *Tropocyclops extensus* was the most common cyclopoid. Calanoids were seldom observed. Mean dissolved oxygen was lowest in the highest treatment mesocosm (8.11 mg/L), with all others ranging from 8.69 to 8.89 mg/L. Further analyses of biofilm, phytoplankton, zooplankton and water quality endpoints are ongoing. Understanding the effects of BAC on aquatic biota, particularly lower-trophic-level organisms, is necessary to assess potential bottom-up effects this compound may have on aquatic food webs. This is work is part of a larger study at IISD-ELA investigating the effects of BACs on aquatic ecosystems.

4.08.P-Tu352 Sulfamethoxazole and Copper Effects on the Plant-Microbiome System in an Agricultural Fertilized Soil

*Alessandra Narciso[1], **Paola Grenni**[1], Francesca Spataro[2], Chiara De Carolis[3], Jasmin Rauseo[2], Luisa Patrolecco[2], Gian Luigi Garbini[3], Ludovica Rolando[3] and Anna Barra Caracciolo[3], (1)Water Research Institute-National Research Council, Italy, (2)Institute of Polar Sciences, National Research Council (ISP-CNR), Italy, (3)Water Research Institute, National Research Council (IRSA-CNR), Italy*

Livestock manure and biosolids as fertilizers in agriculture can be a multi-contamination source for soil ecosystems. Several classes of antibiotics (ABs) such as sulphonamides are commonly used for preventing animal disease and their incomplete metabolization in the organism treated and subsequent excretion determine that animal manure can contain AB residues. On the other hand, copper (Cu) can also be present in soil due to its wide use as a fungicide for several crops.
In recent years, the effects of contaminant co-selection, such as co-resistance and cross- resistance phenomena, have been investigated. Particular concern is due to antibiotic and heavy metal co-presence in terms of antibiotic resistance persistence and spread in agricultural soil.
In this context, a microcosm experiment was performed with an agricultural soil from an organic farm. The soil was differently amended with manure or digestate as fertilizers and spiked with Cu and an AB (sulfamethoxazole, SMX) in presence of *Lactuca sativa.* Adding amendments, an initial increase in soil microbial activity was observed, on the other hand some ARGs increased. In the spiked conditions, the antibiotic almost completely degraded and no bioaccumulation in lettuce was found. Interestingly, SMX and Cu co-presence conditions showed an increase in the sul2 gene, and this can be ascribed to a co-selection phenomenon. Plant-microbiome system was negatively affected by Cu in terms of vegetal biomass and microbial activity, however in digestate conditions this detrimental effect was significantly buffered. Indeed, digestate favoured microbial activity, biodiversity and lettuce growth, independently

from presence or absence of Cu. In conclusion, the active plant-microbiome system established favoured plant growth and the latter in turn positively promoted bacterial diversity and taxa indicative of a good-quality soil, confirming their synergic interactions.

4.08.P-Tu353 Antimicrobial Activity of Cadmium Sulphide Nanoparticles Against Microbial Contaminants from Wastewater Environment

Mzimkhulu Monapathi[1]*, Michael J. Klink*[2] *and Ezinne Ekwujuru*[1]*, (1)Vaal University of Technology, South Africa, (2)Natural Sciences, Vaal University of Technology, South Africa*

Conventional wastewater treatment technologies should treat microbial contaminants that could pose risk to human health. However, some of the treatment processes have proved ineffective. The existing problems are execrated by increasing antimicrobial resistance (AMR) to commonly used antimicrobial agents. There is rapid growth in research on nanomaterials, as alternative antimicrobial agents in wastewater treatment processes. The present study was aimed to treat microbial contaminants from wastewater environments using Cadmium Sulphide Nanoparticles (CdS NPs). CdS NPs were obtained from Vaal University of Technology, Natural Sciences Department, Chemistry division. Antimicrobial assay of the nanoparticles was evaluated against selected potential pathogenic bacterial species (*Escherichia coli* and *Staphylococcus aureus*) using Agar well diffusion and Minimum Inhibitory Concentration (MIC) assays. In a concentration-dependent approach (50 mg/ml, 25 mg/ml and 10 mg/ml), CdS NPs were subjected to the test organisms. In averages, the following zones of inhibition were observed against *E. coli*; 50 mg/ml (14 mm), 25 mg/ml (10 mm) and 10 mg/ml (9 mm), and *S. aureus*; 50 mg/ml (16 mm), 25 mg/ml (13 mm) and 10 mg/ml (12 mm). The following MICs were observed against *E. coli*; 50 mg/ml (3.125 mg/ml), 25 mg/ml (25 mg/ml) and 10 mg/ml (0.391 mg/ml), and *S. aureus*; 50 mg/ml (6.25 mg/ml), 25 mg/ml (6.25 mg/ml) and 10 mg/ml (no inhibition observed). Antimicrobial activity in the present study was confirmed by the formation of zones of inhibition and low MIC values. CdS NPs have shown that they do exhibit antimicrobial properties. The present study is aligned to Sustainable Development Goals 3 and 6, which champion for good health and well-being and provision of clean water for all by 2030. Nanotechnology has made substantial contribution in wastewater decontamination, and thus warrants further research.

4.08.P-Tu354 Can the Type of Inhibitor Interfere with the Adsorption Dynamics of Antibiotics in Granular Anaerobic Sludge?

Elias Gabriel Fernandes de Rezende[1]*, Matheus Neves de Araujo*[2]*, Thiago Vinicius Ribeiro Soeira*[2] *and Rogers Ribeiro*[1]*, (1)Environmental Biotechnology Laboratory - Faculty of Animal Science and Food Engineering - FZEA/USP, Brazil, (2)Biological Processes Laboratory (LPB), São Carlos School of Engineering (EESC), University of São Paulo (USP), Brazil*

The presence of antibiotics in environmental compartments is mainly attributed to the discharge of treated effluent from wastewater treatment plants (WWTP). Biological processes are key players to achieving satisfactory removal of antibiotics in WWTP. Biotransformation and sorption to sludge are the main mechanisms identified in the removal of these compounds in biological reactors. These mechanisms occur simultaneously, but in some cases, it is necessary and advantageous to evaluate them separately. Partitioning of the biotransformation and sorption of antibiotics is commonly accomplished by inhibiting the biological activity of microorganisms to prevent biotransformation. The aim of this work is to assess whether the type of inhibitor can modify the adsorption dynamics of antibiotics in granular anaerobic sludge. Different inhibitors were evaluated to determine the concentration required for inhibition. After this, the removal of the antibiotics ofloxacin, norfloxacin, perfloxacin, ciprofloxacin, trimethoprim, sulfacetamide, sulfadimethoxine, sulfamethoxazole and sulfadiazine was evaluated using batch reactors under the following experimental conditions: (i) biomass inhibited with 8% (v/v) formaldehyde, (ii) biomass inhibited with 2% (v/v) glutaraldehyde, (iii) active biomass without substrate, (iv) active biomass with substrate, and (v) without biomass. The results indicated that the type of inhibitor can interfere with the dynamics of antibiotic removal by adsorption. This difference is more evident in antibiotics that are poorly removed by adsorption during anaerobic digestion, such as those of the sulfonamide class (sufalcetamide, sulfamethoxazole, sulfadimethoxine and sulfadiazine) and trimethoprim. For antibiotics that have a greater affinity for adsorption in anaerobic biomass, such as the fluoroquinolone class (ofloxacin, norfloxacin, perfloxacin and ciprofloxacin), the effect of the inhibitor on adsorption is lower. The initial findings suggest that the use of inhibitors to assess antibiotic adsorption should be carefully approached. First, the minimum concentration for inhibition must be determined and the feasibility of its application assessed. Secondly, the type of antibiotic must be taken into account, if it has an affinity for removal by adsorption the inhibitor will not have an effect on adsorption, otherwise the effect of the inhibitor will be greater.

Disclaimer/Disclosure: This study was sponsored by the Fundação de Amparo à Pesquisa do Estado de São Paulo (FAPESP) [grants numbers 20/15087-8 and, 2022/0436-7] and financed in part by the Coordenação de Aperfeiçoamento de Pessoal de Nível Superior - Brasil (CAPES) - Finance Code 001.

4.08.P-Tu355 Enhanced Antibiotic Removal in Anaerobic Wastewater Treatment Using Granular Activated Carbon

Thiago Vinicius Ribeiro Soeira[1], *Elias Gabriel Fernandes de Rezende*[2], *Matheus Neves de Araujo*[1] *and Marcia Helena Rissato Zamariolli Damianovic*[1], *(1)Biological Processes Laboratory (LPB), São Carlos School of Engineering (EESC), University of São Paulo (USP), Brazil, (2)Environmental Biotechnology Laboratory - Faculty of Animal Science and Food Engineering FZEA-USP, Brazil*

Antibiotics can have a number of adverse effects on human health and the environment, requiring their removal in wastewater treatment plants (WWTPs). Anaerobic biological reactors have been highlighted as a sustainable and economically viable alternative for wastewater treatment, particularly during the methanogenic phase. This study aimed to evaluate the presence of granular activated carbon (GAC) as a conductive support material in a methanogenic hybrid reactor (R1) for the removal of antibiotics (Ciprofloxacin, Norfloxacin, Ofloxacin, Enrofloxacin, Pefloxacin, Sulfamethoxazole, Sulfadimethoxine, Sulfadiazine, Sulfacetamide, and Trimethoprim) in synthetic wastewater. To enable comparisons to be made, polyurethane foam was used as a non-conductive support material in a second reactor (R2). Both reactors had the same design characteristics and were operated in continuous flow for 182 days at four different hydraulic retention times (HRTs) (18h, 12h, 8h and 4h, orderly). Removal efficiency was evaluated using an online SPE system and liquid chromatography interfaced with mass spectrometry QTRAP 5500 HPLC-MS/MS. In general, the treatment decreased antibiotics concentration in effluents. The reduction in HRT decreased the antibiotic removal efficiency in both reactors. However, in all four operating conditions, R1 showed higher removal rates (73,5%, 65,6%, 54,6%, and 53,5% respectively) compared to R2 (47,4%, 52,2%, 41,5%, and 42,3%, respectively), revealing that the presence of conductive support material enhances antibiotic removal efficiency in anaerobic methanogenic reactors. For most antibiotics, the statistics show that there are no significant differences between the removal efficiencies of the 18h and 12h HRTs, but there are for the 12h, 8h and 4h HRTs ($p > 0.05$). These results show that the 12h HRT is the best suited to the removal of these antibiotics in methanogenic hybrid reactors containing GAC as a conductive support material, when compared to all the other operating conditions and support material. High rates of removal efficiency of chemical oxygen demand (95.86%), carbohydrate (97.05%) and protein (93.26%) were also achieved in this operating condition for R1. These findings indicate that the incorporation of conductive materials, such as GAC, can be an effective alternative for optimizing the treatment of wastewater contaminated by antibiotics, contributing to the sustainability and efficiency of treatment processes.

Disclaimer/Disclosure: This study was sponsored by the Fundação de Amparo à Pesquisa do Estado de São Paulo (FAPESP) [grants numbers 2023/08707-8, and 2020/15087-8] and financed in part by the Coordenação de Aperfeiçoamento de Pessoal de Nível Superior - Brasil (CAPES).

4.08.P-Tu356 Advancing Antimicrobial Resistance Control: Electro-Oxidation Technology for Wastewater Treatment with Comprehensive Ecotoxicology Assessment

Thara Methale Velakkath Paramba[1], *Indumathi M. Nambi*[2] *and Henner Hollert*[3], *(1)India, (2)IIT Madras, India, (3)Evolutionary Ecology and Environmental Toxicology, Goethe University Frankfurt, Germany*

The emergence and dissemination of antibiotic-resistant bacteria (ARB) and antibiotic-resistance genes (ARGs) in aquatic ecosystems represent a pressing global health concern. Conventional wastewater treatment approaches inadequately address this challenge, underscoring the urgency for innovative solutions such as electro-oxidation (EO) technology. However, the safety and sustainability of EO-treated wastewater, particularly with respect to toxicity and risk, necessitate rigorous evaluation.
This study addresses the pivotal challenge of assessing the safety and sustainability of EO technology in wastewater treatment, with a specific focus on its efficacy in eradicating ARB and ARGs while minimizing the production of toxic byproducts. Employing comprehensive toxicity and risk assessment methodologies, conducted at Goethe University Frankfurt, to evaluate EO-treated wastewater. Secondary effluent samples collected from real Sewage Treatment Plants (STPs) in Chennai subjected to electrochemical oxidation in a 50 L pilot-scale batch reactor. The reduction in bacterial counts and their Multidrug Resistance index and the reactor's efficacy in demineralizing 9 ARGs using qPCR technique were evaluated across various treatment intervals.
Results indicate EO's efficacy in eliminating ARBs, ARGs, and DNA concentrations in 45 minutes, significantly curtailing operational costs and environmental footprint by eliminating need for extra

chemicals. EO emerges as a comprehensive, eco-friendly solution, generating zero sludge. Notably, this study elucidates fluctuations in toxicity levels pre- and post-EO treatment, offering critical insights into potential toxic byproducts and their concentrations in EO-treated wastewater samples, imperative for ensuring the safe discharge of treated effluent into larger water bodies.
The study holds profound implications for policymakers and stakeholders, informing them of EO technology's efficacy in combating AMR while addressing associated risks and toxicity concerns. By shedding light on both the efficacy and toxicity aspects of EO technology, this research contributes significantly to advancing our understanding of its role in wastewater treatment and its broader implications for public and environmental health. Consequently, the findings serve as a guiding framework for devising strategies to mitigate AMR and facilitate the safe integration of EO technology into wastewater treatment facilities.

4.08.P-Tu357 Accounting for Microorganisms Yields Stricter Water Quality Criteria and Elevated Ecological Risks of Antibiotics: A Case Study of Sulfonamides in the Yangtze River Delta
*Xinyang Zhang and **Nan Lin**, Shanghai Jiao Tong University, China (Mainland)*
The derivation of water quality criteria (WQC) for antibiotics, such as sulfonamides, is complex and influenced by the inclusion of toxicity data from various organisms, including microorganisms. However, no definitive conclusions have been established on the extent of this influence. This study investigates how different organisms' toxicity data, including microbial data, affect the calculation of WQCs and the subsequent ecological risk assessment for sulfonamide antibiotics in the Yangtze River Delta (YRD), a region with significant antibiotic contamination. We selected 263 toxicity data points for eight common sulfonamides, including sulfamethoxazole (SMX) and sulfamethazine (SM2), to derive WQCs using the Species Sensitivity Distribution (SSD) method. Three types of WQCs were calculated: based on native species (WQC-n), a combination of native and non-native species (WQC-nn), and a combination of species and microorganisms (WQC-nnm). The inclusion of microbial toxicity data led to more conservative short-term WQCs, with values approximately 40.97% to 60.80% lower than those calculated without microbial data. Additionally, monitoring data from the past 15 years in the YRD indicated a 150% increase in notable ecological risks when using the WQC-nnm compared to WQC-n and WQC-nn, particularly under normal pollution scenarios. Despite this increase, there was a slight temporal decline in overall ecological risks observed over the monitoring period. This study underscores the importance of incorporating microbial toxicity data in the derivation of WQCs, as it leads to more protective criteria. The results also highlight the need for further research to refine WQCs, particularly in terms of more accurately reflecting real-world exposure scenarios, such as the complex mixture exposures that often occur in the environment. This study provides a critical foundation for future ecological risk assessments and water quality management practices.

Disclaimer/Disclosure: This study was supported by grant 2022YFC3105800 from National Key Research and Development Program of China.

4.08.P-Tu358 Using Bayesian Networks for Antimicrobial Resistance Risk Assessment: A Conceptual Framework
***Mads Troldborg**[1], Rupert L. Hough[2], Miriam Glendell[3], Kerr Adams[3], Zisis Gagkas[3], Lisa Avery[3], Eulyn Pagaling[3], Zulin Zhang[3], Shashidhar Thatikonda[4], Indumathi M Nambi[5], David Graham[6] and Jan-Ulrich Kreft[7], (1)James Hutton Institute, United Kingdom, (2)Ics, James Hutton Institute, United Kingdom, (3)James Hutton Institute, United Kingdom, (4)Indian Institute of Technology Hyderabad (IITH), India, (5)Indian Institute of Technology Madras, India, (6)Newcastle University, United Kingdom, (7)University of Birmingham, United Kingdom*
Antimicrobial resistance (AMR) poses a significant global challenge. While AMR can evolve in many ways in the environment, the water environment is often shown to be a unifying transmission pathway, with AMR often linked to discharges of inadequately treated wastewaters. Understanding and assessing the risk of AMR is complex. Factors such as limited data, epistemic uncertainties, and the lack of consensus on methodologies hinder the development of robust predictive models. Here, we explore the potential of Bayesian Networks (BNs) as a flexible and comprehensive tool for addressing these challenges.
BNs offer unique advantages for AMR risk assessment. By integrating diverse datasets, including both quantitative and qualitative information, and explicitly accounting for uncertainties, BNs provide a structured probabilistic approach that supports both predictive and diagnostic inference. Their graphical nature enables collaborative model co-construction with experts and stakeholders, fostering transparency,

credibility, and shared understanding of complex AMR dynamics.
In this work, we explore and demonstrate the utility of BN for AMR risk assessment via two interconnected strands. The first involves the application of BNs within a standard Quantitative Microbial Risk Assessment (QMRA) framework to estimate human infection risks arising from exposure to antimicrobial-sensitive and -resistant bacteria via contaminated river water; hence estimating not only the risk of illness but also if the illness is treatable or not. The proposed BBN has a modular structure with each module representing a step along the source-pathway-receptor conceptualisation. The approach is demonstrated on an Indian river catchment (Musi) characterised by high rates of antibiotic manufacturing and discharge.
The second focuses on modelling pharmaceutical pollution in a Scottish river catchment (Ugie) using detailed prescribing data, spatial wastewater treatment data, and pharma-specific properties and linking this to sub-minimum inhibitory concentration selective windows to assess the likelihood of AMR development via qualitative inference.
This work highlights the promise of BNs to navigate the multifaceted challenges of AMR risk assessment, offering a pathway to advance our understanding and inform risk management strategies. Future efforts will focus on refining this framework, incorporating empirical data, and applying it to further real-world case studies to validate its efficacy.

4.08.P-Tu359 Environmental Quality Standards for Antimicrobials: A Challenge for Regulatory Risk Assessment

***Gianna Ferrari**, Swiss Centre for Applied Ecotoxicology, Dubendorf/Lausanne, Switzerland*

Traditionally, environmental risk assessment is concerned with protecting the health of environmental organisms, whereas threats to human health are a part of human health risk assessment. For antimicrobial substances the situation is more complex: antimicrobial substances in water can not only have adverse ecotoxicological effects on aquatic life, but they can also exert selection pressure on environmental bacteria, leading to the selection of pre-existing and even emergence of new antimicrobial resistances. The more widespread and diverse the environmental reservoir of antimicrobial resistance becomes the higher chances of infection and subsequent treatment failure for both animals and humans.
To avoid this, Predicted No Effect Concentrations (PNEC) for resistance selection have been proposed, to be applied in environmental risk assessment alongside PNEC based on ecotoxicological data. The current work compares concentrations of antimicrobial substances in Swiss waters with both ecotoxicological PNEC, as well as PNEC for resistance selection. Beyond this, these environmental concentrations will be used to reflect on the data availability of either PNEC type, how that relates to the underlying methods, and finally how the two PNEC types relate to each other and contextualize their differences.
In a broader context, the question is open as to how this particular challenge in antimicrobial risk assessment can be incorporated into regulatory risk assessment, e.g., into the derivation of Environmental Quality Standards (EQS) PNEC derived under the EU Water Framework Directive (WFD). Presently, the decision of if and how to incorporate resistance selection as an adverse outcome has been up to the individual assessors.
The present work explores one framework that has been used in EQS derivation previously, as well as suggested in guidance documents by the World Health Organization and the Antimicrobial Resistance Industry Alliance. This framework, while simple enough in its application, has several shortcomings, among which are data gaps; for some substances PNEC derivation is challenging because the necessary data is not available.
To further tackle the complexity of the regulatory risk assessment of antimicrobials, the revision of the Technical Guidance Document for EQS seems a next possible step. A collaboration bringing together experts from academia and regulatory risk assessors is needed.

4.08.P-Tu360 Do Clarithromycin, Ciprofloxacin or Tetracycline Pose a Risk for AMR Selection in the Environment? A Check via Classical PEC/PNEC Approach

*Kathi Westphal-Settele[1], Uli Klumper[2], David Kneis[2], Dirk Jungmann[2], Thomas U. Berendonk[2], **Patrick Schroder**[1] and Jens Schonfeld[3], (1)Pharmaceuticals, German Environment Agency (UBA), Dessau-Rosslau, Germany, (2)Technische Universitat Dresden, Germany, (3)German Environment Agency (UBA), Germany*

The overuse of clinically relevant antibiotics in human and veterinary medicine is contributing to the global increase in antimicrobial resistance (AMR). The environment serves as a reservoir for AMR and plays an important role in the development and spread of resistance.
Thus, there is need to develop a standardized risk assessment on the potential of antibiotics to select for

AMR in the environment. Various approaches based on existing data have been used to determine these selection concentrations. However, they have not been adequately validated by experimental data and there is no consensus on the advantages of the different methods for risk assessment.
Here we present a risk assessment approach for AMR with integration of classical exposure assessment (PECAB = predicted environmental concentration of a certain antibiotic) and a standardised effect assessment (PNECresist = predicted no effect concentration for resistance selection) resulting in a PECAB/PNECresist risk quotient.
This approach requires data on environmental threshold concentrations, i.e., antibiotic concentrations which are unlikely to select for AMR. As a basis, we conducted single-strain competition experiments with a variety of environmentally relevant bacteria and used antibiotics from 13 individual antibiotic classes. Finally, based on these data and clinical MIC (minimum inhibitory concentration) values, we developed a methodology to calculate valid minimum selection concentrations (MSCs), which also take fitness costs into account, as PNECresist values.
To illustrate our risk assessment approach, we have used the three clinically relevant antibiotics clarithromycin, ciprofloxacin and tetracycline as examples. The PECAB values were calculated as described in the European Medicines Agency guidelines on the environmental risk assessment of human and veterinary medicinal products. The PNECresist values were calculated using our newly developed online tool Cost-based MSC estimates (soon online).
The results for all three antibiotics will be presented here in form of a flow chart risk assessment approach.
With regard to One Health, a standardised risk assessment of antibiotic resistance selection in the environment, with knowledge of the PNEC values at which resistance selection may occur, is crucial to identify where mitigation strategies are needed.

4.08.P-Tu361 A Risk-Based Quantitative Regulatory Approach to Implement the Assessment of AMR Spread via the Environment in Pharmaceutical Authorisation

***Patrick Schroder*[1]**, *David Kneis[2], Uli Klumper[2], Dirk Jungmann[2], Thomas U. Berendonk[2], Kathi Westphal-Settele[1] and Jens Schonfeld[3], (1)Pharmaceuticals, German Environment Agency (UBA), Dessau-Rosslau, Germany, (2)Technische Universitat Dresden, Germany, (3)German Environment Agency (UBA), Germany*

Antimicrobial resistance (AMR), as one of the most crucial human health problems all over the world, can only be managed if all relevant sectors (human health, animal health, environment) work together as part of a One Health approach. Therefore, the issue of AMR in the environment is now also addressed in the veterinary pharmaceutical legislation and in the draft human pharmaceutical legislation.
So far, standardised approaches for assessing the risk of AMR spread via the environment due to anthropogenic antimicrobial emissions are missing. Here, a quantitative risk-based approach on the implementation of such an assessment in the authorisation procedures for antibiotics as human and veterinary medicinal products is presented.
The approach assumes that the abundance of resistances will be increased in the environment if the antibiotic concentration in a certain habitat leads to selection.
In order to derive a predicted no effect concentration for the selection/spread of AMR via the environment (PNECresist) the research project MSC ok? was carried out to derive a method to calculate realistic environmental minimum selective concentration values (MSCs). These MSCs can directly be used as PNECresist for the assessment approach. To determine the predicted environmental concentration of antibiotic (PECAB) it is suggested to use the standardised methods described in the guidelines on the environmental risk assessment (ERA) for human and veterinary medicinal products.
In line with the ERA for human and veterinary pharmaceuticals, a quantitative risk quotient (RQ) for the risk of AMR spread via the environment due to antimicrobial emissions can be calculated by dividing the PECAB by the PNECresist. If RQ is below 1, no risk is expected, while at RQ above 1 a further selection and spread of AMR has to be assumed.
The presented approach can be used to quantitatively assess the risk for AMR being spread via the environment due to anthropogenic antimicrobial emissions. Although aspects like the risk of AMR being transferred back from the environment to humans or animals are not included in this approach the proposal can be seen as a starting point for future guidance development.

4.08.P-Tu362 The Collaborative AMR Multi-Stakeholder Partnership Platform: A Great Opportunity to Engage with Partners from Around the Globe to Address the Challenges of the

Global Risk of Antimicrobial Resistance

Paola Grenni[1], *Andrea DiCesare*[1], *Sabiha Essack*[2], *Francesca Latronico*[3] *and Nelea Motriuc*[4], *(1)National Research Council, Water Research Institute, Italy, (2)University of KwaZulu-Natal, South Africa, (3)Antimicrobial Resistance Laboratory Coodinator, Food and Agriculture Organization of the United Nations, Rome, Italy, Italy, (4)Quadripartite (FAO, UNEP, WHO and WOAH) AMR Multi-Stakeholder Partnership Platform Coordinator, Italy*

Although antimicrobials play a crucial role in preventing and treating infections, the side effects are the possible antimicrobial resistance (AMR) in humans, animals and environment. AMR is a serious threat to global health, affecting not only the efficiency of treatments, increasing medical risks, but also food safety, food security and economic prosperity, as well as planetary biodiversity and ecosystems. Only a close collaboration between a diverse range of stakeholders at all levels of the One Health spectrum can be an effective tool to counter this phenomenon.

The AMR Multi-Stakeholder Partnership Platform, launched in 2022, is a quadripartite (FAO, UNEP, WHO, WOAH) collaboration on AMR and One Health. It is a global, inclusive and collaborative platform which catalyses a global movement for action against AMR by fostering cooperation between a diverse range of stakeholders at all levels across the One Health spectrum.

The inaugural Plenary Assembly of the Platform at FAO headquarters in 2023 joined more than 130 member delegates from different countries and interest groups. Subsequently, several representatives participated in high-level national and international meetings for strengthening global commitments and accelerating collective action on AMR. For the United Nations General Assembly High-Level Meeting (UNGA HLM) on AMR in New York in Sept. 2024, members of the multi-stakeholder partnership platform, led by the UNGA HLM Action Group, outlined key recommendations to address AMR, with the aim of making tangible progress. These recommendations call for concrete steps to address the growing threat of AMR using the One Health approach.

There is still a lot of work to be done, and all members of the platform are called to collaborate to achieve the next goals.

The Fourth High-Level Ministerial Conference on Antimicrobial Resistance, which took place in November 2024 in Jeddah, Saudi Arabia, was concurrent with the Second Plenary Assembly of the Partnership Platform on Antimicrobial Resistance. This occasion marked the adoption of the Jeddah Commitments, which define practical, actionable and cross-sectoral measures that stakeholders can take to address this complex health problem.

Transforming the Declaration from promise to practice will take an incredible amount of work, finance and political will. We must think outside the box and learn from each other's experiences to find impactful solutions.

4.09 Global Drinking Water Quality: Exposure to Natural and Anthropogenic Contaminants and Their Human-Health Effects

4.09.T-01 Pilot-Scale Suspect Screening and Non-Targeted Analysis with Integrated Toxicity Evaluation of Polar to Non-Polar Organic Contaminants in Tap Drinking Water from Western Oregon, USA.

Peter Bright*, Chloe Fender, Miranda Elizabeth Jackson, Kenneth Lee, Lisa Truong, Robyn Leigh Tanguay and Manuel Garcia-Jaramillo, OSU, United States*

Drinking water contamination is an unbiased appraisal of the relationship between anthropogenic activity and water resources. Securing the quality and availability of drinking water is an escalating global challenge. A key hurdle in mitigating contamination is comprehensively addressing the chemical composition of tap water, as contaminants of emerging concern (CECs), population growth, and the impacts of climate change all exert influence over the predominant chemical constitution of waters. This variable composition similarly makes linking specific health outcomes to exposure difficult, though a growing body of evidence indicates that consuming contaminated drinking water may contribute to the development of chronic diseases associated with prolonged exposure to dilute mixtures of chemicals. Suspect screening (SS) and non-target analysis (NTA) utilizing high-resolution mass spectrometry (HRMS) offer robust capability for evaluating drinking water for mixtures of both known and unknown contaminants. Here we present findings from a 2022 sampling campaign where 12 tap water sources across western Oregon and 1 commercial water source were sampled and analyzed using SS and NTA paired with multi-modal extraction and chromatographic techniques prior to HRMS analysis. The amalgamation of analytical approaches targeting a range of physiochemically polar to non-polar contaminants resulted in 5,000 non-target spectral features. Tentative chemical annotations were made for over 100 features including the CEC benzothiazole-2-sulfonic acid, which was confirmed at the level 1 confidence interval. Toxicity data for the chemical annotations were obtained from the USEPA s

Cheminformatics Hazard Comparison Dashboard revealing potential developmental, reproductive, and carcinogenic risks to humans. Raw tap water samples were evaluated for toxicity using the zebrafish model, demonstrating adverse outcomes in the embryonic photomotor response (EPR) endpoint, a behavioral biomarker of neurotoxic effects of chemical exposures.
Comparison of the number of annotations made across extraction and chromatographic environments helps inform future analytical efforts in identifying the best practices for screening organic contaminants in tap drinking water. This study aims to support regulatory actions through the characterization, prioritization, and in vitro and in vivo toxicity testing of CECs and other contaminants detected in tap drinking water in Western Oregon.

4.09.T-02 Identification and Risk Screening of Micropollutants in Processed Drinking Water

Mulatu Nanusha[1]*, Emil Egede Frøkjær*[1]*, Annaliese Vernon*[1]*, Ida Balsby Jakobsen*[2]*, Peter Lysholm Tuchsen*[3]*, Ida Holm Olesen*[3]*, Liselotte Clausen*[4]*, Ulla Brinkmann Trettenes*[5]*, John Jensen*[6]*, Hans Sanderson*[6]*, Bo Lindhardt*[3]*, Hans-Jorgen Albrechtsen*[1] *and Martin Hansen*[1]*, (1)Technical University of Denmark (DTU), Denmark, (2)TREFOR, Denmark, (3)Novafos, Denmark, (4)HOFOR, Denmark, (5)VandCenter Syd, Denmark, (6)Aarhus University, Denmark*

Groundwater, a vital source of drinking water worldwide, is increasingly vulnerable to contamination from agriculture, healthcare, and industrial activities. The occurrence of various chemicals in drinking water raises health concerns, amplified by the discovery of new substances. Non-targeted screening in combination with risk evaluation offers comprehensive insights into chemical profiles in drinking water and their potential human health risks. Accordingly, a tandem-SPE analyte extraction using HLB and ENVI-Carb was performed on processed drinking water collected from the waterworks outlet. The subsequent LC-HRMS chemical analysis and data processing made the assignment of the chemical structure possible for about 278 features, which represent different chemical classes pesticides, pharmaceuticals, industrial compounds, and others. Using a qualitative risk evaluation based on the margin of exposure (MoE) and risk quotient (RQ), none of the individual compounds, whose MoE and RQ were computed, exceeded the threshold values (1000 for MoE and 1 for RQ). However, when considering the mixture of compounds detected within each sample, the computed values approached the threshold limits for both MoE and RQ. The qualitative hazard evaluation for the remaining compounds, using the USA-EPA hazard comparison chemometrics module, suggested several compounds rated with medium and high ranking levels. Therefore, the combination of NTA chemical profiling and risk evaluation helps explore not only the occurrence of unnoticed contaminants in processed drinking water but also demonstrates the human health concerns of the identified substances.

4.09.T-03 Revealing Per- and Polyfluoroalkyl Substance (PFAS) Contamination and Exposure Pathways in Suriname and Ghana

Carla A. Ng[1]*, Nesta Bortey-Sam*[2]*, Firoz Zulfikar Wahid*[2]*, Osei Akoto*[3]*, Kwadwo A. Asante*[4]*, Daniel K. Amoah*[4]*, Addo Acheampong*[4]*, Anisma Gokoel*[5]*, Leanne Ruiz*[2]*, Xinran Zhu*[2]*, Shan Niu*[6] *and* ***Arundhati Tewari***[2]*, (1)University of Pittsburgh, United States, (2)University of Pittsburgh, United States, (3)Kwame Nkrumah University of Science and Technology, Ghana, (4)CSIR Water Research Institute, Ghana, (5)Academic Hospital Paramaribo, Suriname, (6)Beijing Normal University, China (Mainland)*

Per- and polyfluoroalkyl substances (PFAS) are persistent pollutants with significant health and environmental implications. While global understanding of PFAS contamination is advancing, substantial knowledge gaps remain in lower- and middle-income countries such as Suriname (South America) and Ghana (West Africa), where vulnerable populations face exposure from diverse sources. In Suriname, potential sources include pesticides, firefighting foams, carpets, and plastic manufacturing, while in Ghana, e-waste processing hotspots such as Agbogbloshie and Ashaiman are likely major contributors. Despite these risks, limited data exist on PFAS levels in indoor and outdoor environments in these regions. This project addresses these gaps by evaluating PFAS exposure in Ghana and Suriname through environmental sampling of drinking water, fish, soil, and household dust from urban and rural areas. Sampling targeted high-risk and background sites to capture diverse exposure pathways. PFAS analysis of 40 compounds was performed using liquid chromatography mass spectrometry (LC-MS/MS), complemented by the Total Oxidizable Precursor (TOP) assay to assess precursor transformation. In Ghana, drinking water samples near e-waste processing areas revealed significantly higher contamination levels compared to background regions, with legacy PFOA and other perfluorocarboxylic acids (PFCAs), including PFHxA, being prevalent. Sachet water, which is increasingly used as a drinking water source, was also included as a background reference but still showed PFAS contamination, with PFHxA being the only detected compound. Similarly, fish samples from Ghana demonstrated elevated PFAS concentrations, with tilapia showing the highest levels. PFHxA was the most abundant compound, and legacy PFOS was also detected, highlighting ongoing contamination despite its global phase-out. These findings highlight e-waste sites as significant contributors to PFAS pollution, driven by both current and legacy emissions. Ongoing analyses in Suriname focus on assessing PFAS contamination and precursor dynamics across various regions. By providing initial scoping data, this study addresses critical knowledge gaps and aims to inform evidence-based policies and mitigation strategies to reduce PFAS exposure in vulnerable populations in Suriname, Ghana, and similar regions globally.

4.09.T-04 Challenges of Managed Aquifer Recharge (MAR) - Potential Pathway of Contaminants of Emerging Concern (CECs) into Ground- and Drinking Water Systems or Effective Treatment?
Tabea Mumberg[1]*, Lutz Ahrens*[2] *and Philipp Wanner*[1]*, (1)University of Gothenburg, Department of Earth Sciences, Sweden, (2)Swedish University of Agricultural Sciences (SLU), Department of Aquatic Sciences and Assessment, Sweden*
Managed aquifer recharge (MAR) is a common method to ensure ground- and drinking water quality and quantity, especially in high-populated, arid regions or areas with little aquifer storage capacity. MAR systems artificially infiltrate surface water into groundwater systems and eventually drinking water supplies, but surface waters often contain higher concentrations of contaminants of emerging concern (CECs) that could then enter groundwater systems through MAR. However, the fate of CECs in MAR systems and the controlling parameters of CEC transport within the subsurface are not well understood. We conducted a systematic literature review giving a detailed overview of (1) CEC abundance in surface waters, (2) factors controlling CEC mobility and retention in MAR systems as well as concluding with (3) the identification of key CECs that pass through the MAR system into groundwater reservoirs and drinking water supplies. During the review process, a search string in Scopus and Web of Science was used and followed the PRISMA diagram to screen 1543 papers resulting in 89 included papers. From the reviewed literature, we give recommendations to monitor and optimize MAR systems for upcoming demands of increasing water quality and quantity in a time of exponentially increasing numbers of new CECs. Those recommendations include the need for regular monitoring programs to address seasonal peaks and to achieve a good understanding of highly site-specific parameters. We further recommend the consideration of non-regulated, yet (very) mobile and (very) persistent, compounds in monitoring programs, as well as the redesign of MAR systems including pre-treatment options, treatment trains coupling several treatment steps, or strategic operational planning. This review therefore points out current challenges of CECs entering MAR systems and contributes with clear suggestions towards cost-efficient water treatment options to meet upcoming drinking water guidelines.

Disclaimer/Disclosure: The research was financially supported by a FORMAS Early Career Grant awarded to Dr. Philipp Wanner (grant number 2021-00510).

4.09.T-05 A Harmonized Approach for the Conduction of Treatments and Analytics According to EFSA/ECHA GD on Water Treatment
Michael Kubicki[1]*, David Pelzer*[1]*, Patrick Olaf Helmer*[2] *and Thomas Boultwood*[3]*, (1)Bayer AG, Germany, (2)BASF SE, Germany, (3)Syngenta Ltd., United Kingdom*
In the domain of plant protection product (PPP) authorization under commission regulation (EU) No. 1107/2009, one approval criterion requires to identify transformation products of active substances and their environmental metabolites that may be formed during drinking water treatment (DWT) and conduct a human health assessment.
In August 2023, EFSA and ECHA published a new guidance document on the impact of DWT processes on residues of PPP, biocides, and their environmental metabolites. For PPP, this guidance was entered into force in April 2024.
The guidance describes several individual test procedures to evaluate the transformation of active substances and their metabolites under DWT processes: 1) chlorination, 2) oxidation 3) ozonation, 4) a combined process of pre-oxidation followed by chlorination, 5) UV disinfection and 6) sand filtration. These tests are to be conducted at environmental related concentrations in the range of 1-10?µg/L, with detection and identification of possible transformation products (TPs) by non-target analysis, and concentration estimation through quantification via structurally related compounds. TPs quantified above

0.075 µg/L shall subsequently undergo structure elucidation and need to be further evaluated with toxicity studies and a dietary risk assessment.
Non-target analysis holds promise but lacks clear guidelines, particularly for data processing and filtering algorithms, hindering regulatory applicability. Additionally, suggested tests, conducted in isolated laboratory screens, deviate from real-world waterworks conditions, omitting pre- and post-treatments and potentially yielding "artificial" transformation products.
Despite their regulatory significance, the experimental tests lack essential validation and ring-testing for consistency and reliability. Even the interpretation of how to perform the individual procedures (e.g., concentration of the oxidant) is given by a quiet high flexibility. Within CropLife Europe (CLE) a harmonized approach of all individual test procedures was development to ensure the best possible comparability and reproducibility by running these new regulatory studies at different laboratories. This presentation shares the harmonised approach and the recommendation of the CLE Group for the conduction of treatments and analytics according to the new guidance document on the impact of drinking water processes for plant protection products, biocides and their environmental metabolites.

4.09.P Global Drinking Water Quality: Exposure to Natural and Anthropogenic Contaminants and Their Human-Health Effects

4.09.P-We337 Toxic Legacy of Brazil's Mining Disasters: Micropollutants Profile and Health Risks in Drinking Water after Mariana and Brumadinho collapses

Carolina Panis[1], *Altair Rodrigues Pires De Paula Filho*[2] *and Marcia Castro*[3], *(1)State University of Western Parana, Brazil, (2)Laboratory of Tumor Biology, State University of Western Parana, Brazil, (3)Harvard T.H. Chan School of Public Health, United States*
Brazil has witnessed some of the most severe environmental disasters globally, notably the mining dam collapses in Mariana (2015) and Brumadinho (2019), both located in the state of Minas Gerais. These incidents are regarded as among the largest environmental and labor-related crimes in Brazilian history, collectively resulting in nearly 300 fatalities and causing extensive environmental and social damage. In this study we profiled the micropollutants reported in drinking water from municipalities affected by these disasters, using data from the Brazilian Water Quality Surveillance Information System for Human Consumption (SISÁGUA). Our analysis shows that Minas Gerais state accounted for approximately 70% of recorded exceedances of the maximum residual limits (MRLs) for drinking water in Brazil between 2011 and 2023, with 18,040 entries for Mariana and 5,966 for Brumadinho. Approximately 30% of these data points came from municipalities within the Rio Doce Basin, which supports a population of 3.5 million across 228 cities. Of these, 53 municipalities (serving around 1.4 million people) reported contaminants exceeding MRLs. A total of 65 micropollutants were identified, with 41 detected in at least one city. The top 10 contaminants above MRLs were: lead (3,023 occurrences), selenium (2,430), bromates (1,658), ethylbenzene (1,522), 1,2-dichlorobenzene (1,395), 1,4-dichlorobenzene (1,387), toluene (1,412), xylene (1,417), trihalomethanes (1,320), and haloacetic acids (1,173). Radioactive uranium was also detected above MRLs (157 occurrences). Most of these contaminants have guideline values set by the World Health Organization (WHO) for drinking water and represent a potential long-term risk of cancer and other health impacts. In October 2024, a judicial ruling ordered compensation for residents near the Mariana disaster site, with each affected individual to receive an equivalent of 7,000 USD, acknowledging the uncertainty surrounding long-term health impacts. Current efforts from our study focus on estimating the potential public health impacts of exposure to micropollutants above MRLs among affected populations.

4.09.P-We338 Emerging Contaminant 1,4-Dioxane: Emission Sources, Global Contamination, and Regulatory Disparities

Nan Lin, *Shanghai Jiao Tong University, China (Mainland)*
1,4-Dioxane, a probable human carcinogen, has raised significant environmental concerns due to its widespread occurrence in countries with both known and unknown histories of production and use. While a comprehensive study on its global emissions, environmental distribution, and regulatory frameworks is lacking. This study aims to fill this gap by examining the sources, environmental occurrence, and regulatory measures associated with 1,4-dioxane. We conducted a comprehensive analysis of existing global data on 1,4-dioxane emissions, focusing on industrial and domestic sources. Using publicly available data and emission inventories from countries like the U.S., Germany, and Japan, we quantified emissions from industrial processes, particularly surfactant manufacturing, polyester production, and ethoxylation processes. Additionally, we estimated emissions from household products based on their usage and disposal patterns, which have previously been underrepresented in studies of 1,4-dioxane. Environmental data on the presence of 1,4-dioxane in groundwater, surface water, drinking water, and

indoor air were also reviewed. Our findings indicate a shift in emission sources, from industrial activities to diffuse emissions linked to consumer products, especially in regions without a history of 1,4-dioxane production. We found that emissions from household products may exceed those from industrial sources in certain areas, highlighting the growing significance of domestic contributions to global contamination. Environmental contamination is no longer limited to groundwater, with increasing detections in surface waters and indoor air. We also reviewed regulatory frameworks across different countries, noting disparities in toxicity assessments and regulatory limits. These differences are largely due to varying interpretations of 1,4-dioxane s mode of action and limited toxicity data. This study underscores the need for more accurate emission inventories, comprehensive environmental monitoring, and clearer global regulatory standards to address the environmental and health risks posed by 1,4-dioxane.

Disclaimer/Disclosure: Dr. Nan Lin was supported by grant 42307545 from the National Natural Science Foundation of China, and grant 2022YFC3105800 from National Key Research and Development Program of China.

4.09.P-We339 Collective Challenge: Contaminant Mixtures in United States Private, Public, and Bottled Drinking Water

*Paul Bradley[1], **Kelly L. Smalling**[1], Kristin M Romanok[1], Elizabeth Medlock Kakaley[2] and Daniel L. Villeneuve[2], (1)U.S. Geological Survey, United States, (2)U.S. Environmental Protection Agency, United States*

In the United States, point-of-use drinking water is supplied via private tapwater (predominantly private wells), public-supply tapwater, and bottled water. Differences in management, monitoring, and messaging and lack of directly intercomparable exposure data influence the actual and perceived quality and safety of these different drinking water supplies and directly impact consumer decision making. An analysis of point-of-use drinking-water contaminant-mixture exposures and corresponding potential human-health effects of private-supply, public-supply, and bottled drinking water was conducted by aggregating exposure results and harmonizing apical health-benchmark-weighted and bioactivity-weighted effects predictions across studies conducted and published previously by this research group. Simultaneous exposures to multiple inorganic and organic contaminants of known or suspected human-health concern are common across all three drinking water supplies, with substantial variability observed in each and no systematic difference in predicted cumulative risk between the supplies. The results emphasize the need for improved understanding of the adverse human-health implications of long-term exposures to low level inorganic /organic contaminant mixtures across all three distribution pipelines.

4.09.P-We340 Per- and Polyfluoroalkyl Substances in Tapwater: A Case Study in the United States

***Kelly L. Smalling**[1], Kristin M. Romanok[1], Paul Bradley[1] and Tyler Wagner[2], (1)U.S. Geological Survey, United States, (2)U.S. Geological Survey, PA Cooperative Fish & Wildlife Research Unit, United States*

Drinking-water quality is a rising concern worldwide emphasizing the need to broadly assess exposures and potential human-health effects at the point-of-use. Exposures to per- and poly-fluoroalkyl substances (PFAS) are also of concern in the US and globally, however, there is limited information on PFAS in residential tapwater, especially from private-wells. We conducted a reconnaissance to compare human PFAS exposures in unregulated private-well and regulated public-supply tapwater. Tapwater from 716 locations (269 private-wells; 447 public supply) across the US was collected during 2016-2021. Concentrations of PFAS were assessed by three laboratories and compared with land-use and potential-source metrics to explore drivers of contamination. The number of individual PFAS observed ranged from 1 to 9 with corresponding cumulative concentrations (sum of 16 detected PFAS) ranging from 0.348-346 ng/L. Seventeen PFAS were observed at least once with PFBS, PFHxS and PFOA observed most frequently in approximately 30% of the samples. Across the US, PFAS profiles and estimated median cumulative concentrations were similar among private wells and public supply tapwater. We estimate that at least one PFAS could be detected in about 45% of US drinking-water samples. These detection probabilities varied spatially with limited temporal variation in concentrations/numbers of PFAS detected. Benchmark screening approaches indicated potential human exposure risk was dominated by PFOA and PFOS, when detected. Potential source and land-use information was related to cumulative PFAS concentrations, and the number of PFAS detected; however, corresponding relations with specific PFAS were limited likely due to low detection frequencies and higher detection limits. Information generated supports the need for further assessments of cumulative health risks of PFAS as a class and in combination with other co-occurring contaminants, particularly in unmonitored private wells where information is limited or not available.

4.09.P-We341 Challenges and Gaps in the Human Health Risk Assessment of Per- and Polyfluoroalkyl Substances: Drinking Water Perspective

Adeolu Aderemi *and Ehi Idahosa-Taylor, Water Research Centre Ltd., United Kingdom*

The detection of per- and polyfluoroalkyl substances (PFAS) in surface water, groundwater, and drinking water at levels exceeding statutory or non-statutory regulatory limits has become a growing global concern due to the hazard posed to both environmental and public health. Some PFAS have been linked with various adverse health effects in humans including liver and developmental effects, decreased vaccine response in children, increased cholesterol levels and testicular cancer. However, there is a lack of consensus across the scientific community about the levels of PFAS that are of health concern. This paper reviews the varying approaches used by the various authoritative bodies in different countries in deriving health-based guideline values (HBGVs) for PFAS. For the continuous protection of public health, this paper also derives provisional HBGVs for a few PFAS with limited toxicological data which are monitored in drinking water under the EU and UK Drinking Water Inspectorate directives. The lack of toxicological data for the vast majority of PFAS and the inconsistencies in approaches to data interpretation across the authoritative organisations presents challenges for risk assessment. In the EU Drinking Water Directive for the sum of 20 PFAS, only 7 of the chemicals have HBGVs. Different organisations have proposed varying health-based guideline values (HBGV) and drinking water limits for the same compounds. For example, there is a > 4 order of magnitude difference in the HBGVs recommended by Health Canada and US Environmental Protection Agency for perfluorooctanoic acid or perfluorooctane sulphonic acid which demonstrates the complexities with PFAS risk assessment.

4.09.P-We342 Toxicity and Exposure Assessment of NDMA in Drinking Water: Multi-Omics Profiling using Zebrafish

Raquel Chaves[1]*, Joao Rodrigues*[2]*, Ana Gil*[2] *and Miguel M. Santos*[3]*, (1)CIIMAR - Interdisciplinary Centre of Marine and Environmental Research, University of Porto, Portugal, (2)CICECO, University of Aveiro, Portugal, (3)FCUP- Faculty of Sciences of University of Porto and CIIMAR-UP: Interdisciplinary Centre of Marine and Environmental Research, University of Porto, Portugal*

The presence of nitrosamines in drinking water has emerged as an ongoing concern, posing significant challenges to both water safety and public health. As widespread environmental contaminants with potent carcinogenic properties, nitrosamines, particularly N-nitrosodimethylamine (NDMA), remain a major focus of research due to their potential health risks. Despite this, the precise toxicity mechanisms and the full extent of their impact on human health have not been fully understood. NDMA is classified as a probable human carcinogen (Group B2) by the International Agency for Research on Cancer (IARC), and the World Health Organization (WHO) has set a guideline value of 100 ng/L for this compound in drinking water. Previous toxicological studies, often relying on in vivo models, such as Danio rerio, have highlighted the significant adverse effects of NDMA exposure. However, there is still a gap in our understanding of its toxicity at the molecular level, which is critical for assessing both environmental and human health risks.

In this study, we applied a multi-omics approach, combining transcriptomics and untargeted Nuclear Magnetic Resonance (NMR) metabolomics, to assess the metabolic and molecular impacts of NDMA exposure at different concentration levels on zebrafish. The results revealed significant alterations in both the transcriptomic and metabolomic profiles of zebrafish exposed to NDMA. NMR metabolomics identified several metabolites that were significantly affected by NDMA exposure, such as organic acids, amino acids and nucleosides. The most impacted pathways include purine and pyrimidine metabolisms and energy metabolism (enhanced glycolysis and TCA cycle activation). These alterations suggest that NDMA exposure disrupts fundamental biochemical processes, potentially leading to cellular stress, impaired metabolism, and carcinogenic effects.

This study underscores the importance of using multi-omics approaches in environmental toxicology. By capturing a broad spectrum of molecular alterations, from gene expression to metabolite levels, omics offer a deeper mechanistic understanding of how environmental contaminants like NDMA affect biological systems. The produced knowledge is essential in environmental pollutants risk assessment and for the development of more effective public health and regulatory strategies to protect human health and the environment.

4.09.P-We343 Suspect Screening and Non-Target Transformation Product Identification in Samples Derived from Drinking Water Treatment Processes

Rory Mumford[1]*, Daniel T. Evans*[1] *and Chris Kirkman*[2]*, (1)Environmental Fate and Metabolism, Smithers, United Kingdom, (2)Smithers, United Kingdom*

The EFSA guidance document on the impact of water treatment processes on residues of active substances or their metabolites in water abstracted for the production of drinking water was issued in August 2023

(DOI: https://doi.org/10.2903/j.efsa.2023.8194). In general, the guidance covers the identification and exposure assessment of transformation products (TPs) of Biocidal and Plant Protection Products (PPPs) using experimental and in silico methods for hazard prediction. This does not just cover the effects of water treatment on the active substances but also their transformation products and their toxicological assessment.
Drinking water treatment is generally performed using chlorination, ozonation or UV treatment processes for disinfection or a combination of several processes. The guidance provides methods for simple laboratory procedures that are intended to be performed without the need for complex and expensive equipment.
Performing the laboratory tests is not the major challenge when considering this guidance, rather, it is the analysis.
The number and complexity of potential transformation products can be significant when considering the multiple processes involved. One of the most extensively used analytical methods for suspect and non-target analysis is high resolution mass spectrometry coupled with liquid chromatography.
This presentation focusses on the strategies that can be employed using liquid chromatography with High Resolution Accurate Mass Spectrometry (HRAM) to perform suspect screening and non-target identification on samples derived from water treatment processes.

4.09.P-We344 EFSA Drinking Water Treatment Guidance - Challenges of Experiments for Plant Protection Products and Biocides
*Hauke Kattwinkel, **Volker Wedek** and Kristina Hoffmann, knoell Germany GmbH, Germany* The authorisation and use of plant protection products (PPP) and biocidal products (BP) are regulated by Regulations (EU) 1107/2009 and (EU) 528/2012 to ensure a high level of protection for human health and the environment.
During the evaluation of active substances (a.s.) present in PPP and/ or BP a conclusion on the impact of water treatment processes on residues of a.s. and their metabolites in water abstracted for the production of drinking water could not be drawn so far. To fill the existing information gap, EFSA and ECHA jointly developed a new guidance document, namely Impact of water treatment processes on residues of active substances or their metabolites in drinking water.
Even not yet started, the experimental assessment of drinking water treatment processes according to the new guideline has already occurred with significant challenges. As outlined by different stakeholders, especially Contract Research Organisations (CRO), inter-laboratory reproducibility varied. Obviously, the experimental designs described in the guideline are lacking precise information and are far away from a standard study plan. For the future, there is a substantial need for harmonised and agreed approaches in testing drinking water treatment processes. This does also include the use of analytical methods to identify and quantify transformation products during water treatment processes, non-target screening vs. radio-analysis. Further, low laboratory capacities for conducting comprehensive studies and uncertain high costs associated with unclear experimental procedures have hindered progress in this area so far.
Moreover, the timelines set by the European Commission for implementing the new guidance document are tight, leaving little room for stakeholders to adapt and conduct the required experiments and potential subsequent toxicity and dietary safety risk assessments of transformation products in time. Therefore, it is highly recommended to develop a study concept management on purpose at an early stage.
This contribution should provide a critical view of the challenges associated with the experimental and analytical procedures outlined in the guidance document, including the formation and identification of transformation products during water treatment processes. By highlighting these challenges, we aim to facilitate a more informed discussion on the need for harmonised approaches in experimental assessing drinking water treatment processes

4.09.P-We345 Chemical Monitoring in Biota for the Water Framework Directive: Large-Scale Implementation in France with in situ Caging of *Gammarus* sp. (Crustacea)
*Caroline Arcanjo[1], Olivier Geffard[2], Dorothee Bolzan[3], Amelie Vlandas[3], Berangere Pergeline[4], Luc Pereira-Ramos[4], Baptiste Casterot[4], Miguel Nicola[5], Magali Barnier[6], Sylvain Jolly[6], Jean-Pierre Rebillard[7], Jonathan Canal[7], Yohan Laigle[8], Cecile Dubois-Coli[8], Olivier Fontaine[8], Xavier Bourrain[9], Olivier Perceval[10], **Anthony Gérard Edouard Mathiron**[11] and Guillaume Jubeaux[12], (1)BIOMAE, France, (2)INRAE Riverly, France, (3)Artois Picardie Water Agency, France, (4)Seine Normandie Water Agency, France, (5)Rhin Meuse Water Agency, France, (6)Loire Bretagne Water Agency, France, (7)Adour Garonne Water Agency, France, (8)Rh ne-Mediterranee-Corse Water Agency, France, (9)Clermont-Ferrand University, France, (10)Office FranCais de la Biodiversite, OFB, France, (11) BIOMAE, France, (12) BIOMAE, Château Gaillard, France*

The application of WFD involves to member states of European Union two objectives: (1) assess the chemical status of water bodies, by checking their compliance with regulatory Environmental Quality Standards (EQSs) for priority substances and, (2) monitor trends of contamination. As an integrative matrix allowing measurements for many chemicals, biota-EQS have been included in WFD for bioaccumulative substances. Active biomonitoring using *Gammarus* sp. is applied in France based on a French standardized protocol. The purpose of this proposal is to give feedback on the application of this normalized method in France and illustrate how it meets the WFD requirements.

Gammarids are collected in breeding ponds, kept under laboratory conditions and calibrated before in situ exposure. After 21 days of exposure, inorganic and organic compound concentration levels were measured. These measurements are used to assess (1) compliance of water bodies towards crustaceans-EQS but also fish-EQS through their adjustment with the PULEX tool (Predict Usual Level Effects Xenobiotics) and (2) trends of contaminants based on available BBAC (i.e., bioavailable background assessment concentration).

Between 2018 and 2024, 4.231 cagings were performed (i.e., 891 stations and 102 campaigns). 98% of the caging systems were successfully retrieved. According to AFNOR-NF-T90-721, chemical analyses (at defined LOQ) were performed on 90% of stations.

In response to WFD requirements, the present study shows that in situ caging of *Gammarus* sp. has been successfully implemented in France since 2018. This method allows to (1) check compliance of water bodies to crustaceans/molluscs and fish-EQS, as illustrated for benzo(a)pyrene and PFOS compounds respectively, and (2) monitor contamination trends of historical (e.g., PCB, PHA) and more emerging (e.g., PFOS) compounds. Additionally, this method offers the opportunity to measure ecotoxicological effects in exposed gammarid as life traits and molecular markers.

4.10 Sustainable Remediation of Mining Impacts and Critical Materials Recovery

4.10.T-01 Mining Sites in Czechia as Potential Sites for Critical Element Recovery

Miroslav Cernik *and Martin Palusak, Technical University of Liberec, Czech Republic*

The Czech Republic has a long tradition of mining raw materials, and uranium has played a very prominent role. In the Middle Ages, silver was mined in many locations in Bohemia. Since 1945, uranium has been mined on an industrial scale at 23 uranium deposits. Most Czech mines were closed for ecological and economic reasons promptly after the Czech Velvet Revolution in the early 1990s. The ecological damage caused by long-term mining activity is enormous in many locations, and therefore the remediation is still incomplete and costly. Long-term human activity in the mines results in the weathering of rocks (oxidation) and releasing heavy metals into mine water. Weathering sulfide ores, common in mining sites, leads to generating acid mine drainage (AMD). With the cessation of mining, groundwater does not return to its natural state, but AMD flows (or has to be pumped out of the mine) for many decades.

The established practices in treating these acid mine waters include mainly aeration, raising the pH by lime milk, and precipitating heavy metals. The waters are treated in on-site treatment plants, which are permanent operations requiring constant supervision, the addition of chemicals, and toxic waste disposal. The whole operation is very costly and requires technologies that run for decades. Sustainable remediation of these waters, waste piles, and tailings is a challenge, especially in the possibility of simultaneous economically less demanding and sustainable remediation and recovery of critical elements in these wastes.

Within the framework of the Sustainable Remediation of Radionuclide Impacts on Land and Critical Materials Recovery (SURRI) project, a categorization of more than twenty sites under the responsibility of DIAMO s.e., was made. These are sites where uranium, precious metals, and other elements were mined. Selected sites were sampled, and the critical element content was evaluated. Further assessment was made on the possibility of recovering these elements from waste or solid samples from the sites. Experiments on the samples are underway and will be evaluated.

Disclaimer/Disclosure: This work was supported by the European Union s HORIZON EUROPE WIDERA 2021 programme under the SURRI project, Grant Agreement No 101079345.

4.10.T-02 A Deep Green Clean? Plant and Nature-Based Systems for Mining Wastes Risk Management and Critical Element Recovery

Frances Burrel[1], *Nhung Nguyen*[2], *Martin Palusak*[2], *Anna Bohmova*[2], *Marlita Marlita*[2], *Martin Pusztai*[2], *Jorge Ascencio Damian*[3], *Veronika Hlavackova*[2], *Alena Sevcu*[2], *Miguel Gomez-Gonzalez*[4] *and Andrew Cundy*[1], *(1)GAU-Radioanalytical Laboratories, University of Southampton, United Kingdom, (2)Institute for Nanomaterials, Advanced Technologies and Innovation, Technical University of Liberec, Czech Republic, (3)Division of Sustainable Energy and Environmental Engineering, Osaka University, Japan, (4)Diamond Light Source Ltd, United Kingdom*

Former metal mining areas present complex remediation and rehabilitation challenges, due to widespread metal contamination, and/or the presence of sulphide minerals, which may promote acid mine drainage. For uranium mining and milling tailings significant risk may also be generated by the presence of elevated radioactivity. The SURRI project is a current Horizon Europe programme aimed at developing new integrated risk management methods for legacy uranium mining and production sites, and historic metal mining sites, in Eastern Europe. The frequently large areal extent of contaminated materials at these former mining sites, coupled with the potential application (and lower application cost) of phyto- and other nature-based approaches to manage risk in both aquatic and terrestrial systems, make phytoremediation strategies potentially strong candidates for incorporation into integrated risk management and element recovery systems at these sites. This presentation outlines work within the SURRI project targeted on the application of plant or phyto-based techniques for risk management of tailings and other wastes, and critical element recovery, targeting U, Zn and As.

Initial work was performed on *Lemna* sp., due to their rapid growth potential and trace element accumulation capabilities, and their ability to be integrated into existing mining waste treatment systems such as settlement or clarification ponds, and constructed wetland areas. Locally collected *Lemna* sp. demonstrated a linear relationship between uptake and dosing concentration for U, with more complex relationships observed for As and Zn. Within-plant distribution and metal(loid) speciation was evaluated via SEM and XANES analysis. Results indicate that *Lemna* sp. are a promising candidate for recovery of critical elements from mining waters, given their widespread geographic distribution and rapid growth, particularly in final effluent polishing stages prior to final discharge. Ongoing work examines the transfer of elements between tailings and plant / rhizosphere using by Time of Flight Mass Spectrometry mapping, and the potential combination of electrokinetic remediation with phyto-extraction and critical metal recovery, with an overall aim of producing readily-implementable nature-based technologies that can be used both for effective risk management and metal recovery.

Disclaimer/Disclosure: The authors acknowledge Diamond Light Source for time on I14 beamline under rapid access proposal: mg39225, and support from Horizon Europe, via project HEU101079345.

4.10.T-03 Comparative Study Between Bacteria and Fungi Immobilized in Alginate Hydrogels for Bioremediation and Biorecovery of Selenium

Eduardo Gonzalez-Morales[1], *Esther Peula-Ruiz*[1], *Esther Diaz-Arinero*[2], *Antonio Luis Medina-Castillo*[3], *Modesto Torcuato Lopez-Lopez*[4], *Mohamed Merroun*[1] *and Miguel Angel Ruiz-Fresneda*[1], *(1)Department of Microbiology University of Granada, Spain, (2)Department of Physiology, Genetics and Microbiology University of Alicante, Spain, (3)Department of Analytical Chemistry University of Granada, Spain, (4)Department of Applied Physics University of Granada, Spain*

The immobilization of microorganisms in polymeric hydrogel matrices has gained attention in recent years for their application in environmental bioremediation and biorecovery of critical materials. This process, which improves cellular integrity, transport, handling and resistance against external stressors, is usually performed with bacteria and fungi due to their high metabolic diversity, rapid growth and evolution rate, and versatility.

The present study aims to compare the Se(IV) removal capacity of the bacterial species *Stenotrophomonas bentonitica* and the fungal species *Aspergillus ochraceus* (filamentous fungi) and *Rhodotorula mucilaginosa* (yeast). The obtained results show the great potential of Na-Alginate as an immobilization matrix for the tested species. Scanning electronic microscope images show that the biomass is widely distributed throughout the polymeric matrix in all cases. The Se(IV) removal experiments revealed the great capacity of *S. bentonitica* (70% Se(IV) elimination after one week of incubation) and *A. ochraceus* (97% Se(IV) removal rate after two weeks of incubation). *R. mucilaginosa* was also capable of reducing Se(IV) but the efficiency of the process is much lower to efficiently remove and transform soluble Se(IV) into Se(0) nanoparticles with industrial interest. In all cases, amorphous Se(0) nanospheres were produced but only crystalline (monoclinical or trigonal) nanoparticles were produced by *S. bentonitica*. All these Se(IV) reduction products are widely distributed and retained inside the polymeric matrix, demonstrating the potential of these systems to be used in Se(0) nanoparticle recovery. These results highlight the great potential of bacteria and especially filamentous fungi immobilization in alginate hydrogels for removing Se(IV) from the environment and recover Se nanoparticles with industrial interest within the framework of the circular economy.

4.10.T-04 Realising the Potential - Electrokinetic Technologies for Risk Management and Critical Element Recovery at Former Mining Sites: Outputs from the HEU SURRI Project

***Daniele Silvestri*[1]*, Martin Palusak*[1]*, Frances Burrel*[2]*, Veronika Hlavackova*[1]*, Miroslav Cernik*[1] *and Andrew Cundy*[2]*, (1)Institute for Nanomaterials, Advanced Technologies and Innovation, Technical University of Liberec, Czech Republic, (2)GAU-Radioanalytical Laboratories, University of Southampton, United Kingdom*

The SURRI project (HEU101079345) is an ongoing Horizon Europe programme aimed at developing new integrated risk management methods for legacy uranium mining and production sites (and other sites with potentially toxic trace element-containing wastes) in Eastern Europe. This presentation outlines work performed on the development of low-energy electrokinetic risk management and element recovery techniques, targeting metal-contaminated wastes from historic mining sites in the Czech Republic (here, the Zlate Hory site a polymetallic deposit exploited historically mainly for Au, with lesser Cu and Zn). Electrokinetic Remediation, EKR, involves implantation of electrodes in a substrate and the application of an electrical current to move, contain or recover contaminants through electromigration, electroosmosis, or electrophoresis. EKR is a highly flexible technique in which electrodes can be arranged in multiple ways, enabling it to work in various geometries and around site infrastructure. Importantly, EKR can work effectively in low permeability substrates which are not amenable to treatment by many existing techniques such as soil flushing or washing, e.g. low-permeability soils or tailings.

Electrokinetic systems tested and reported here used either a small diameter U-tube set-up or a larger volume cell with water reservoirs and ports for porewater measurement. Preliminary trials on the smaller U-Tube system showed rapid development of a pH gradient (due to hydrolysis of water at the electrodes), with spiked solutions showing migration of elements towards the oppositely charged electrode. In the larger test system spiking of test materials with Zn showed rapid electromigration of the Zn2+ ion away from the central injection point, and accumulation in the cathodic well, significantly exceeding diffusion-only migration rates. Further tests are underway with real site materials, and will be reported subsequently. These low-energy electrokinetic systems are promising tools for mining waste remediation and metal recovery, having been demonstrated previously at TRL7 and above. Ongoing work within SURRI examines up-scaling of electrokinetic treatment and recovery systems on real site materials, and integration of electrokinetic and bioremediation (including the potential biostimulation impact of electrokinetics on indigenous metal-tolerant or -recovering microbes) or phyto-recovery methods, with the aim of producing integrated technologies at TRL5 or higher.

Disclaimer/Disclosure: The authors acknowledge support from Horizon Europe, via project HEU101079345.

4.10.T-05 Sequential Treatment Chain for Removal of Iron and Selective Recovery of CRMs from Mine Effluent from Nizna Slana Ore Deposit (Eastern Slovakia)

Daniel Kupka*, Lenka Hagarova, Zuzana Bartova and Eva Macingova, Institute of Geotechnics of the Slovak Academy of Sciences, Slovakia*

In February 2022 a sudden major outbreak of mine waters from the abandoned flooded siderite mine in Nižná Slaná (Eastern Slovakia) caused an ecological disaster on the Slaná River. High-concentrated mine-impacted effluents transported huge amounts of toxic heavy metals and metalloids directly to the recipient stream. The high iron content resulted in a significant red coloration of the river, which was observed several tens of km downstream and contamination crossed borders to Hungary. The permissible limits for pollution of surface water in the Slaná River have been exceeded heavily and adversely affected the living quality of the river.

The passive treatment system using anoxic limestone drains (ALD) as alkalinity generators followed by aerobic wetland was considered. Unfortunately, mine water from the deposit is highly supersaturated with respect to ferric iron (oxy)hydroxides and alkali metal jarosites. Appreciable concentrations of dissolved

Fe2+ or Al3+ would result in precipitation and coating of limestone surfaces and in rapid clogging of the interstitial spaces. In addition, high sulphate concentration of the water (> 30g/L) would cause problems with clogging of ALD drains due to gypsum precipitation.
Instead, an active water treatment approach using Fe-oxidizing bacteria and tuneable iron(III) precipitation, followed by selective recovery of metallic CRMs was proposed. This study outlines a sequential treatment chain for removal of iron in mine effluents of the Nizna Slana ore deposit, along with recover of Mn, Co and Ni.

Disclaimer/Disclosure: Funded by the EU NextGenerationEU through the Recovery and Resilience Plan for Slovakia under the project No. 09I03-03-V03-00083.

4.10.P Sustainable Remediation of Mining Impacts and Critical Materials Recovery

4.10.P-Mo374 Secondary Minerals Formed in Mine Impacted Waters (Smolnik-Slovakia)

*Jaroslav Briancin, Lenka Hagarova, Daniel Kupka and **Zuzana Bartova**, Institute of Geotechnics of the Slovak Academy of Sciences, Slovakia*

Mine impacted waters (MIW) are a serious environmental problem in many countries around the world. Specific form of MIW, so called acid mine drainage (AMD), occurs predominantly in sulphide deposits and originates from the weathering of sulphide bearing rocks. Iron- and sulphur oxidizing chemolithotrophic, acidophilic bacteria play an essential role in the weathering of sulphide minerals such as pyrite, chalcopyrite, tetrahedrite etc. They accelerate the oxidation of ferrous and sulphur entities in metal sulphides, leading to mineral dissolution and acid generation.
The precipitates themselves, iron ochre, are mainly formed on surfaces that are in contact with mine water. These are mainly coatings on stones and organic material in the stream. However, larger pieces can be observed in places where the flow slows down and the mineral (ochre) has room to form.
The main mineral in the outflow is Schwertmannite (Fe8O8 (OH) 8 2x(SO4)x nH2O. Along with elements such as iron and sulphur, also metalloids such as arsenic or antimony co-precipitate here.
Schwertmannite has an interesting reddish colour and there is a possibility of its use as a natural pigment. After drying, it is brittle and easily crushed into a fine powder. It can be easily mixed with a base medium, such as oil, and the resulting colour is intense and well applicable.

Disclaimer/Disclosure: Funded by the EU NextGenerationEU through the Recovery and Resilience Plan for Slovakia under the project No. 09I03-03-V04-00697.

4.10.P-Mo375 Study of Microbial Communities of Mine Drainage from the Mária Mine in Rožňava, Slovakia

***Lenka Hagarova** and Daniel Kupka, Institute of Geotechnics of the Slovak Academy of Sciences, Slovakia*

This study focuses on the microbial diversity of mine water drainage from the Rožňava mine, Slovakia, with an emphasis on non-culturable bacterial communities. We conducted a comparative analysis using two molecular approaches: 16S rRNA gene sequencing and whole-genome sequencing (WGS). Water samples were collected and subjected to high-throughput sequencing to describe the structure, diversity, and relative abundance of microbial taxa. Our results revealed the bacterial community composition based on sequencing of the V3-V4 regions of the 16S rRNA gene, highlighting key genera with the highest relative abundance, such as Gallionella, Crenothrix (Verrucomicrobia), Bdellovibrio (Proteobacteria), Acidocella (Proteobacteria), Flavobacterium (Bacteroidetes), and Acidithiobacillus (Proteobacteria). In contrast, WGS provided greater resolution of taxonomic diversity, revealing additional bacterial taxa not detected by 16S rRNA gene sequencing alone. For instance, WGS identified bacterial species such as *Methylotenera versatilis*, *Gallionella capsiferriformans*, and even ammonia-oxidizing archaea like *Candidatus Nitrosoarchaeum limnia*. Measured abiotic factors, including pH, metal concentrations, and temperature, can significantly impact the composition and structure of the microbial communities present. This comparative approach underscores the advantages and limitations of each method, providing valuable insights into the microbial ecology of mine-impacted environments and informing strategies for potential mine water treatment and secondary raw material recovery.

Disclaimer/Disclosure: Funded by the EU NextGenerationEU through the Recovery and Resilience Plan for Slovakia under the project No. 09I03-03-V04-00271.

4.10.P-Mo376 Potential for Critical Element Recovery using Autochthonous Microbial Community from Former Mining Sites

Veronika Hlavackova[1], *Vira Velianyk*[1], *Nhung Nguyen*[1], *Martin Palusak*[1], *Cristina Povedano-Priego*[2], *Frances Burrel*[3], *Mohamed Merroun*[2], *Andrew B. Cundy*[3], *Miroslav Cernik*[1] *and Alena Sevcu*[1], *(1)Inst. of Nanomaterials, Advanced Technologies and Innovation, Technical University of Liberec, Czech Republic, (2)Department of Microbiology, Faculty of Science, University of Granada, Spain, (3)GAU-Radioanalytical Laboratories, University of Southampton, United Kingdom*

The remediation of areas contaminated by past and ongoing mining activities remains a significant environmental challenge, necessitating innovative strategies to address the complex nature of the pollution at these sites. Traditional approaches for treating industrial waste and mine water primarily involve aeration and the precipitation of heavy metals using lime milk, which introduces calcium-rich minerals. However, these methods generate toxic sludge as a by-product. Given the limited availability of metal resources, mitigation of heavy metal pollution at former mining sites offers an opportunity to recover critical elements, aligning with the growing emphasis on circular economy principles.

Microorganisms are particularly promising for remediation of polluted areas because (1) they are ubiquitous, inhabiting diverse ecological niches worldwide, and (2) they can survive and function under extreme conditions, employing various mechanisms to protect themselves against toxic loads. This study, developed under Horizon Twinning program SURRI, aims to characterize the composition of autochthonous microbial communities in response to mine water treatment. It also explores their potential not only to tolerate the toxicity of heavy metal toxicity but also to facilitate the recovery critical metals from contaminated areas.

Initially, microbial activity was screened at several former mining sites in the Czech Republic using molecular-genetic methods. Subsequently, microbial genera were isolated from original samples using standard media. The ability of these isolates to tolerate heavy metals was evaluated through minimal inhibitory concentration assay and assessments of growth performance in the presence of toxic metals. Advanced electron microscopy techniques (SEM and STEM) were employed to verify the capacity of isolated microorganisms to process and precipitate heavy metals.

In this presentation, we will provide data on the natural microbial load at several former mining sites in the Czech Republic. The isolated bacterial representatives demonstrated varying abilities to overcome the presence of heavy metals under environmental toxic loads, both before and after mine water treatment. In summary, our findings highlight microorganisms as promising candidates for the remediation of contaminated sites and the recovery of critical elements, owing to their ubiquity, remarkable adaptability, and capacity to transform, precipitate and accumulate heavy metals.

Disclaimer/Disclosure: The work was supported by the Horizon Europe Twinning, the SURRI project (GA No 101079345). The authors thank Dr. Pavel Kejzlar for the help with scanning electron microscopy and Dr. J. Riha for bioinformatic analysis.

4.10.P-Mo377 Performance of Sediment Bacterial Communities Upon Acid Uranium Mining: Advances for In Situ Recovery Technology

Fadwa Jroundi[1], *Cristina Povedano-Priego*[1], *Pierre Grizard*[2], *Michael Descostes*[3] *and* ***Mohamed Merroun***[1], *(1)Department of Microbiology, Faculty of Science, University of Granada, Spain, (2)ORANO Mining, France, (3)ORANO Mining; Centre de Geosciences, MINES ParisTech, PSL University, France*

Naturally occurring uranium (U) is a key resource in addressing the growing interest in the nuclear energy industry. Its efficient extraction is commonly achieved through acid In Situ Recovery (ISR), a process that induces alterations to the surrounding environment. Rehabilitation of ISR-impacted environment could be performed through natural attenuation, biostimulation or via bioaugmentation using indigenous microorganisms capable of acid neutralization and heavy metal immobilization. The behaviour and performance of these microorganisms under acidic conditions remain largely unknown, requiring further investigation to better understand their role in the environment restoration.

In this study, batch experiments were carried out using sediments collected from U ore at the Zoovch Ovoo deposit in Mongolia. Hipersaturation of the sediments was achieved by using synthetic aquifer water at different pHs (4.5, and 5.5). Furthermore, bacterial consortium including sulphate-reducing (SRB) and iron-reducing (IRB) bacteria, previously identified as sediment native microorganisms, were added to the different treatments. A mixture of lactate and acetate (and glycerol) was utilized as carbon sources to stimulate the growth of either sediment indigenous heterotrophic or added SRB/IRB bacteria. The microcosms were incubated under anoxic conditions at 28ºC for 5 months. Black precipitates appeared after 2 weeks of incubation only in the experiments at pH 5.5, where more reducing conditions were detected by pH and Eh monitoring. DNA extractions and 16S rRNA Illumina sequencing showed significant differences in the bacterial diversity. The predominance of *Clostridium* spp., and Desulfovibrio was notable at pH 5.5, while more heterogenous distribution of genera was observed at pH 4.5, except for Desulfotomaculum and members of Tissierellales, especially abundant in presence of glycerol. Microscopic and spectroscopic techniques (VP-FESEM and EDX) were performed to analyse the precipitates formed in the sediments. At pH 4.5, the minerals exhibited corroded appearance, whereas at pH 5.5, numerous framboidal pyrites (FeS?) and bacterial cells were observed co vering the sediments. These outputs highlight the critical role of the indigenous bacterial community in restoring reducing conditions necessary for uranium immobilization. They also offer valuable insights into developing effective rehabilitation strategies for environments impacted by acid ISR activities.

4.10.P-Mo378 Biosynthesis of Selenium Nanoparticles by *Variovorax* sp., a Bacterium Isolated from a Former Gold and Copper Mine

*Vira Velianyk[1], **Alena Sevcu**[1], Trung Le Duc[1], Mohamed Merroun[2] and Veronika Hlavackova[1], (1)Institute for Nanomaterials, Advanced Technologies and Innovation, Technical University of Liberec, Czech Republic, (2)University of Granada, Spain*

Former mining sites are a source of microorganisms with promising potential applications in biotechnology, bioremediation, and medicine. *Variovorax* sp. was isolated from sludge collected at a depth of 270 meters below ground level in the former gold and copper mine in Zlate Hory, Czechia. The strain demonstrated high metal tolerance, as evidenced by its minimum inhibitory concentrations and growth rate when exposed to selenium, copper, zinc, and lead. Subsequently, *Variovorax* sp. was further tested for its ability to synthesize elemental selenium nanoparticles (SeNPs) from selenium nitrate. The SeNPs were characterized using UV-Vis spectroscopy, transmission electron microscopy (TEM), and scanning electron microscopy (SEM). The nanoparticles exhibited irregular shapes, including round, elongated, and tooth-like forms, with sizes ranging from 100 to 200 nm and an average size of approximately 150 nm. Notably, the nanoparticles were detected inside the cells. Thus, *Variovorax* sp. shows promise for the recovery of elemental selenium from mine wastewaters.

4.10.P-Mo379 Selenite Reduction by Bentonite Microbial Communities: Insights from a Long-Term Study for Deep Geological Repositories

***Cristina Povedano-Priego**[1], Fadwa Jroundi[1], Maria del Mar Abad-Ortega[2], Isabel Guerra-Tschuschke[2] and Mohamed Merroun[1], (1)Department of Microbiology, Faculty of Science, University of Granada, Spain, (2)Centro de Instrumentacion Cient fica (CIC), University of Granada, Spain*

Deep Geological Repository (DGR) is the preferred strategy for the safe storage and management of high-level radioactive waste (HLW). This approach employs a multi-barrier system that includes sealing spent nuclear fuel within metal canisters, surrounded by engineered barriers such as highly compacted bentonite, and placing the whole structure within a stable geological formation. All projected scenarios for DGR suggest the probability of a long-term release of radionuclides (e.g., U-235, and Se-79) to the environment. Natural occurring microorganisms in bentonite have the potential to minimize the migration of radionuclides by promoting their immobilization. This study investigated the impact of microbial diversity on the immobilization of Se(IV) through its reduction and transformation in bentonites over a long-term experiment designed to simulate DGR conditions.
Water-saturated bentonite was treated with Se(IV) and inoculated with a bacterial consortium consisting of Pseudomonas, Stenotrophomonas, Shewanella, Bacillus, and Amycolatopsis. All the microcosms were incubated anaerobically for 4 years. DNA extractions and Next Generation 16S rRNA gene sequencing were conducted to analyze the shifts in microbial diversity. The results revealed that Firmicutes and Proteobacteria were the most abundant phyla. Interestingly, the presence of Desulfobacterota was detected, which could play a key role in Se(IV) immobilization through bioreduction. Precipitates ranging in color from orange to black were observed in Se(IV)-treated microcosms. Microscopic and spectroscopic techniques (VP-FESEM, STEM/HRTEM, EDX) were performed to characterize the Se(0) nanostructures (SeNS). Different crystalline forms of Se(0) were identified, including monoclinic (m-Se), and trigonal (t-Se) with diverse morphologies such as spheres, nanotubes, and hexagonal structures.
These results highlight the direct and indirect potential of bentonite-associated microbial communities in the immobilization of Se(IV). Through reduction to elemental selenium and subsequent biotransformation,

selenium is converted into a more stable and less biologically toxic element. These findings provide critical insights into the role of microbial activity in enhancing the long-term safety of DGRs.

Disclaimer/Disclosure: Financial support by the Horizon Europe SURRI project (GA No 101079345).

4.10.P-Mo380 A Hyphal Mat Solution? Root-like Fungal Networks for Mining Waste Remediation and Metal Bioextraction

Nhung Nguyen[1], *Cristina Povedano-Priego*[2], *Vira Velianyk*[1], *Trung Le Duc*[1], *Veronika Hlavackova*[1], *Martina Maruskova*[1], *Martin Palusak*[1], *Frances Burrel*[3], *Miguel Gomez-Gonzalez*[4], *Mohamed Merroun*[2], *Andrew Cundy*[3] *and Miroslav Cernik*[5], *(1)Department of Applied Biology, Institute for Nanomaterials, Advanced Technologies and Innovation, Technical University of Liberec, Czech Republic, (2)Department of Microbiology, University of Granada, Spain, (3)GAU-Radioanalytical Laboratories, University of Southampton, United Kingdom, (4)Diamond Light Source, Harwell Science and Innovation Campus, United Kingdom, (5)Institute for Nanomaterials, Advanced Technologies and Innovation, Technical University of Liberec, Czech Republic*

Mining activities in Europe have caused extensive environmental issues, including acid drainage and metal pollution, necessitating sustainable remediation strategies. Within the Horizon Europe project SURRI, this study explores fungi as a biotechnological solution for remediating metal-contaminated sites and recovering critical metals and metalloids such as Mn, Zn, Co, Cu, Pd, As, and Se. Unlike the well-studied bacterial systems, fungi offer unique advantages, including their ability to biosorb, sequester, and detoxify metals through their mycelial networks, making them promising agents for critical element recovery. Samples from uranium and gold mining sites in the Czech Republic were analyzed to isolate indigenous fungal species. These fungi were identified using ITS rRNA sequencing and characterized for their growth, tolerance, and metal accumulation capacities using advanced techniques like SEM, STEM, and ICP-MS. The fungi were tested on solid and liquid media under metal(loid) concentrations ranging from 1 to 16 mM. A total of 29 fungal strains were isolated, predominantly from the Zlaté Hory site. These fungi demonstrated high tolerance to metals, particularly Zn and Mn (4 8 mM), with moderate tolerance to metalloids such as As and Se, the latter tolerated up to 16 mM by some strains. Metal tolerance patterns (Zn = Mn > Co > Pb > Cu > As > Se) aligned with the concentration hierarchy of elements in the mining samples. Colony size decreased with higher metal concentrations, indicating a trade-off between growth and tolerance. Certain fungi exhibited selective accumulation, with Pb being sequestered efficiently at acidic pH 5 and As at neutral pH 7. Precipitation of Mn, Co, Pd, and As was observed on fungal agar plates within 7 days. These findings highlight the potential of fungi for critical element recovery due to their adaptability and selective metal sequestration. Future studies will assess their performance using real mine water and investigate fungi-bacteria combinations to enhance recovery efficiency. These advancements could lead to sustainable management of contaminated mining sites.

4.10.P-Mo381 Circular Economy Approach for Cr^{6+} Adsorption from Water Using Black Carbon

Mohammad Gheibi, *Martin Palusak, Daniele Silvestri, Miroslav Cernik and Stanislaw Waclawek, Institute for Nanomaterials, Advanced Technologies and Innovation, Technical University of Liberec, Czech Republic*

The demand for effective water treatment systems has risen significantly due to increasing industrial activity and growing environmental concerns. Heavy metal contamination, such as chromium (Cr??), poses serious risks to both human health and ecological systems because of its high toxicity and persistence. Among the various methods available, adsorption stands out as one of the most effective techniques for removing heavy metals from water. However, adsorbents can be expensive, so the search for inexpensive yet effective alternatives has generated significant interest.

This study explores the potential of black carbon (BC), a versatile and cost-effective material commonly used in applications like plastic fillers, conductive systems, and tire reinforcements, as an efficient and affordable adsorbent for removing Cr?? from water. Because of its distinct physical and chemical characteristics, BC has shown great promise for use in water treatment applications.

The impact of changing pH, adsorbent mass, and contact time on the removal effectiveness of Cr?? was examined in batch adsorption experiments as part of the experimental investigation. Energy Dispersive X-ray Analysis and Field Emission Scanning Electron Microscopy were used to describe the BC material, which showed a porous structure that was conducive to adsorption. The findings demonstrated that raising BC mass considerably improves the removal effectiveness of Cr??, with near-complete removal occurring

at 150 mg under acidic circumstances. Furthermore, the best results were obtained at acidic and neutral pH values, which achieved near-complete elimination for 150 mg in 5 minutes and over 70% clearance for lower BC masses in 10 minutes. The study shows that BC is an excellent adsorbent of Cr??, particularly in acidic environments, providing a long-term option for water treatment applications.
The study suggests that BC, an industrial cheap product, is an effective adsorbent for Cr??, supporting circular economy principles through waste minimization and reuse. BC's potential for cost-effective, sustainable water treatment is highlighted, and future research is recommended to optimize operational conditions and further explore adsorption mechanisms.

4.10.P-Mo382 Low-Energy Electrokinetic Remediation for Site Risk Management and Metal Recovery

Ruby Lunn[1]*, Shaun Hemming*[1]*, Frances Burrel*[1]*, Phillip Warwick*[1] *and Andrew Cundy*[2]*, (1)University of Southampton, United Kingdom, (2)Ocean and Earth Science, University of Southampton, United Kingdom*
Electrokinetic Remediation, EKR, is a flexible remediation and element recovery technique that involves implantation of electrodes into a substrate and the application of an electrical current to move, contain, degrade or recover contaminants through electromigration, electroosmosis, or electrophoresis. Electrodes can be arranged in multiple ways, enabling EKR to work in various geometries and around site infrastructure. Importantly, EKR can work effectively in low permeability substrates which are not amenable to treatment by many existing techniques such as soil flushing or washing, e.g. low-permeability soils or tailings. As such, EKR has potential application for treatment of a wide variety of historic mining and metal production wastes, having been previously demonstrated at Technology Readiness Level (TRL) 7, e.g., for chromium ore processing residues. This presentation outlines and reviews previous research on EKR for wastes (and soil / sediment) treatment and element recovery at higher TRL. In particular it assesses a) the use of sacrificial steel electrodes to inject iron into substrates to generate impermeable barriers for subsurface containment and stabilisation, or reductively precipitate redox-sensitive contaminants (chromium, technetium), and b) showcases recent facility investments (via the UK s National Nuclear User Facility funding) which enable assessment of electrokinetic treatment potential for nuclear and other site wastes, and the ability of EKR to fence or contain and concentrate elements under realistic groundwater flow rates and conditions.

4.10.P-Mo383 A Sustainable Hybrid Thermo-Chemical Recycling Approach for High-Performance Graphite Regeneration from Spent Lithium-ion Batteries

Anusha Vishwakarma *and Subrata Hait, Indian Institute of Technology Patna, India*
Recycling spent lithium-ion batteries (LIBs) has recently witnessed notable advancements. Current recycling techniques primarily focus on recovering valuable metals, often leaving spent graphite (SG) as secondary waste with limited attention. However, SG, characterized by its high surface area, robust structural integrity, and desirable electrochemical properties, presents an attractive resource for repurposing and new applications, addressing both environmental and economic concerns. This study employs an integrated mild acid leaching and low-temperature pyrolysis process to regenerate graphite (RG) from spent LIBs. Initially, the anode current collector was preprocessed to separate graphite from Cu foil, yielding uniform anode black powder (SG) with a particle size of <200 µm. The SG was treated with varying concentrations (10%, 30%, and 50%) of acetic acid solution to leach out lithium and other impurities. Inductively coupled plasma-mass spectroscopy (ICP-MS) analysis of the leached solutions identified the 30% acetic acid solution as the most effective, achieving >95% removal of metal impurities from SG. The regenerated graphite (RG30) treated with 30% acetic acid was subsequently subjected to thermal treatment in a muffle furnace at different temperatures (300°C, 500°C, 700°C, and 900°C) to eliminate residual impurities. Results revealed that pyrolysis at 700°C was most efficient in decomposing organic binders, such as polyvinylidene fluoride (PVDF), and electrolytes in the electrode material. Microcharacterization techniques, including X-ray diffraction (XRD) and scanning electron microscope (SEM) analyses of the RG, recovered post-thermal treatment (RG700), confirmed the successful removal of residual impurities and restoration of its microstructure. The results also indicated the carbonization of organic impurities, forming an amorphous carbon layer on the graphite surface. Subsequent TGA analysis will validate the removal of residual impurities, and the electrochemical performance of the regenerated graphite samples will be assessed to confirm their alignment with commercial graphite (CG) in terms of

initial charge capacity and retention rates. This study demonstrates an eco-friendly and scalable method for recovering high-quality graphite from spent LIBs, offering a sustainable approach to LIB recycling.

4.11 Marine and Coastal Pollution: Novel Quality Assessment Strategies and Management

4.11.T-01 Tracing Contaminants in Seafood Across the Global Ocean: Current Status and Future Management Directions

Maria Vittoria Barbieri[1], *Maria del Pilar Gonzalez Munoz*[2], *Valentina Araya Pique*[1], *Julian Blasco*[2] *and Ethel Eljarrat*[1], *(1)IDAEA-CSIC, Spain, (2)ICMAN-CSIC, Spain*

Chemical contaminants, including pharmaceuticals, personal care products, microplastics, metals, nanoparticles, and persistent organic pollutants (POPs), pose severe risks to marine ecosystems due to their toxicity, persistence, and global prevalence. Despite efforts under the EU Marine Strategy Framework Directive (MSFD) to achieve Good Environmental Status (GES), gaps remain in addressing unregulated and emerging pollutants, compounded by inadequate legislation in many regions. This study consolidates data from 2018 to 2024 across FAO zones to assess pollutant levels, impacts on marine ecosystems and human health, and strategies for improving monitoring and regulation. A review of 42 articles on organic and 41 on inorganic pollutants, covering 20 contaminant classes such as phthalates, bisphenols, UV-filters, Cd, Pb, and Hg, analyzed data from 163 species for organic and 177 for inorganic pollutants. A total of 48,479 samples have been retrieved, providing a comprehensive view of contamination patterns worldwide. Results show widespread contamination by microplastics and organic pollutants, particularly phthalates and POPs, with hotspots in FAO Zones 61 (Western Central Pacific) and 51 (Western Indian Ocean). The Mediterranean (FAO Zone 37) showed high levels of DEHP and DiNP, worsened by its semi-enclosed geography, while the Southwest Atlantic (FAO Zone 41) exhibited elevated levels of UV-filters and pharmaceuticals. Benthic species like flathead grey mullet (Mugil cephalus) showed significant bioaccumulation. Inorganic contaminant levels varied by region and species. FAO Zone 27 (Northeast Atlantic) reported lower Cd, Pb, and Hg levels in predators like albacore (Thunnus alalunga) but elevated Pb and Hg in smaller species such as European pilchard (Sardina pilchardus). FAO Zone 51 (Western Indian Ocean) showed the lowest contamination overall, though localized Pb hotspots were found. FAO Zone 34 (Central-Eastern Atlantic) had high Hg levels, and the Mediterranean recorded the highest Hg concentrations, surpassing safety thresholds in species like gilt-head bream (Sparus aurata). These findings underscore the need for stricter regulations, enhanced waste management, and international cooperation to address pollution sources. Persistent pollutants remain critical concerns due to their resistance to degradation. Improved monitoring frameworks are essential to track emerging contaminants and ensure the health of marine ecosystems and seafood safety.

Disclaimer/Disclosure: This research was funded by the European Union NextGeneration EU as part of the MITECO program for the Spanish Recovery, Transformation and Resilience Plan (Recovery and Resilience Facility of the European Union established by the Regulation (EU) 2020/2094), and was entrusted to CSIC, AZTI, SOCIB, and the universities of Vigo and Cadiz.

4.11.T-02 Spatial Distribution of Per- and Polyfluoroalkyl Substances (PFAS) in Natural and Restored Intertidal Wetlands in the Scheldt Estuary

Thimo Groffen[1], *Ken Schoutens*[1], *Jeremy Donaire Zamora*[1], *Olivier Gourgue*[2], *Lieven Bervoets*[1] *and Stijn Temmerman*[1], *(1)University of Antwerp, Belgium, (2)Royal Belgian Institute of Natural Sciences, Belgium*

Due to high human activity in coastal ecosystems, tidal marshes have become one of the most threatened natural ecosystems on the planet, with a significant decline in their ecosystem services as a result. The tidal marshes, flats and channel networks of estuaries each have their own distinct hydrodynamics, sedimentology and ecology which may affect the environmental fate and behaviour of pollutants. Intertidal areas may retain pollutants, hence impacting organisms that live, forage, or breed in these areas. Therefore, we investigated the spatial distribution of PFAS in sediments of intertidal areas in the Scheldt estuary (N Belgium & SW Netherlands), and to what extent this varies between different eco-geomorphic zones and between an old natural intertidal site (drowned land of Saeftinghe) and recently restored intertidal site (Hedwige-Prosperpolder; HPP), where tides were re-introduced. Furthermore, we investigated whether this distribution is affected by sediment characteristics and distance from the estuarine main channel. Associations between PFAS levels in sediments from the marshes and plants were investigated. Finally, we compared PFAS levels prior and after re-introduction of tides in the restoration site.

Our results show signs of both historical and recent PFAS emissions, and suggest that the geomorphology of intertidal areas could play a role in the spatial distribution of PFAS in sediments. In general, the vegetation and the higher intertidal elevation in the marshes slow down currents, causing more deposition of finer sediment and higher PFAS concentrations. Distance from the main channel, grain size and organic matter content were less determining factors in the environmental fate. The re-introduction of tidal flooding in HPP leads to an enrichment with PFAS. Three PFAS were detected prior to tidal re-introduction, whereas eight PFAS were detected after. Concentrations of PFOS, PFOA and PFBS were respectively 12x, 3x and 5x higher after re-introduction. Although environmental risks in the intertidal areas were not assessed in this study, the enrichment could be beneficial for the Scheldt estuary and North Sea, as PFAS are filtered from the estuary and ecological risks in the estuary and adjacent sea are likely reduced. Moreover, removal of contaminated sediment beds and plants from intertidal areas would allow for remediation of the ecosystem, something which is more difficult when the pollution stays in the estuarine channel or sea.

Disclaimer/Disclosure: This project received funding from the Research Foundation Flanders (FWO), in terms of a junior postdoctoral grant (12ZZQ21N) and senior postdoctoral grant (1205724N) to TG.

4.11.T-03 Patterns of Accumulation of Plastic Additives in Top Predator Sharks from the North Atlantic Ocean

Roger Casado[1]*, Luis Alves*[1]*, Marco F.L. Lemos*[1]*, Filipe R. Ceia*[2]*, Matteo Baini*[3]*, Matteo Galli*[3]*, Cristina Panti*[3]*, Filipa Bessa*[4]*, Maria Fossi*[3] *and Sara Novais*[1]*, (1)MARE Marine and Environmental Sciences Centre & ARNET - Aquatic Research Network, ESTM, Polytechnic of Leiria, Portugal, (2)University of Coimbra, MARE Marine and Environmental Sciences Centre / ARNET Aquatic Research Network, Portugal, (3)Department of Physical Science, Earth and Environment, University of Siena, Italy, (4)Centre for Functional Ecology - Science for People & the Planet (CFE), Department of Life Sciences, Faculty of Sciences and Technology of the University of Coimbra, Portugal*

Millions of tons of untreated plastic enter the oceans annually, leaching harmful additives such as phthalates (PAEs), which are recognized as endocrine-disrupting chemicals. Phthalates have been detected in several marine organisms, and especially in top predators such as sharks, but their prevalence along the North Atlantic is unknown. This study aimed to evaluate the differences in PAEs accumulation in different tissues of blue sharks (Prionace glauca) caught in offshore waters and those captured in coastal areas. The objective was to establish a profile of the most prevalent phthalates in the marine environment by analysing their concentrations in the tissues of marine top predators. A total of 34 blue sharks were opportunistically sampled as bycatch in the North Atlantic, with muscle and liver tissues collected in situ. Eleven PAEs compounds were quantified using gas chromatography-mass spectrometry (GC-MS). Statistical analyses were conducted to assess differences in PAEs concentrations between tissue types and across geographic locations where the sharks were captured. Results showed that Di(2-ethylhexyl) phthalate (DEHP), Dibutyl phthalate (DBP), Di-n-octyl phthalate (DNOP), and Diisobutyl phthalate (DIBP) were the most abundant phthalates in both tissues, while Diisononyl phthalate (DINP) was mostly detected in the liver, likely due to differences in metabolic processing. Moreover, higher phthalate concentrations were observed in the liver compared to muscle, reflecting the liver s role in detoxification. Notably, coastal sharks exhibited greater accumulation of phthalates across both tissues, with differences between geographic regions being more pronounced for the muscle tissue, which showed a clear gradient of decreasing contamination with distance from shore. These findings highlight a link between geographic proximity to anthropogenic activities and contaminant levels in top marine predators. The study underscores the utility of muscle tissue in assessing short-term environmental contamination and of liver tissue in detecting phthalates with distinct chemical properties, and also highlights the intricate dynamics of phthalate accumulation in marine predators, providing critical insights into how environmental factors and tissue properties influence contaminant bioaccumulation, thereby enhancing our understanding of ocean pollution and its potential ecological and food web impacts.

Disclaimer/Disclosure: The authors thank Fundação para a Ciência e a Tecnologia (FCT) for funding the Strategic Projects granted to MARE (doi.org/10.54499/UIDB/04292/2020 and doi.org/10.54499/UIDP/04292/2020), the project granted to the Associated Laboratory ARNET (doi.org/10.54499/LA/P/0069/2020), the grant awarded to RC (2024.01169.BD) and the contracts to FC (DL57/2016/CP1370/CT90), FB (https://doi.org/10.54499/DL57/2016/CP1370/CT0106) and SN (doi.org/10.54499/CEECINST/00060/2021/CP2902/CT0007).

4.11.T-04 Minimum Necessary Copper Release Rates for Effective Antifouling Coatings in European Coastal Waters

Maria Lagerström[1]*, Marcel Butschle*[2]*, Ann Larsson*[3]*, Jer me Cachot*[4]*, Markus Schackmann*[5]*, Florane Le*

Bihanic[6] and Kim Dam-Johansen[2], (1)Chalmers University of Technology, Sweden, (2)Technical University of Denmark, Denmark, (3)University of Gothenburg, Sweden, (4)University of Bordeaux, France, (5)Esslingen University, Germany, (6)Marine natural park of the Arcachon Bay (PNMBA), French Biodiversity Agency (OFB), France
Vessel hulls are commonly coated with antifouling paints which release biocides directly into the surrounding water to prevent the attachment of marine organisms, thereby avoiding increased fuel consumption. Cuprous (I) oxide is the most frequently employed biocide in antifouling coatings today and acts to inhibit fouling through the release of copper ions. Antifouling products are regulated within the EU by the Biocidal Products Regulation which dictates that they should not be toxic beyond necessity, i.e., have a higher release rate of biocides than necessary for their efficacy. However, there is insufficient knowledge on the minimum required release of copper for antifouling coatings to be effective in different European waters making it difficult, if not impossible, to challenge if a product is overdosing.
In this study, the minimum necessary (or critical) release rate of copper to inhibit macrofouling was investigated in European coastal waters, with study sites in Atlantic (Arcachon Bay, France), Kattegat (Hundested, Denmark) and Skagerrak (Tjärnö, Sweden) waters. The efficacy of various antifouling coatings with differing copper contents (from 6 to 32 wt%) and their copper release rates were evaluated during a six-month field study, employing a combination of visual inspection and X-ray Fluorescence (XRF) analysis. The aim of the study was to determine the critical release rate of copper to deter macrofouling organisms at each site and to investigate whether it differs depending on the composition of the local fouling community.
The findings of this study indicate that a release rate of 7 µg/cm2/day was sufficient to inhibit macrofoulers at all three sites. Results also indicate that the critical release rate is a parameter that coating manufacturers can optimize, as the performance of the coatings was not solely dependent on the copper release rate. A release rate of 7 µg/cm2/day could serve as a benchmark for dose optimization of coatings for both the yacht and ship sectors to reduce their environmental impact.

4.11.T-05 Current Levels of OCPs Residues in Sediments: Towards an Environmental Risk Assessment for a Coastal Lagoon in the Southern Gulf of Mexico

***Víctor Gabriel Elías-García**[1], Guadalupe Ponce-Velez[2], Francisco S. Hernandez-Pulido[3], Alfonso V. Botello[2] and Hugo F. Olivares Rubio[2], (1)Posgrado en Ciencias del Mar y Limnología, Universidad Nacional Autonoma de Mexico, Mexico, (2)Laboratorio de Contaminacion Marina, Instituto de Ciencias del Mar y Limnología, Universidad Nacional Autonoma de Mexico, Mexico, (3)Laboratorio de Hidrobiolog a, Instituto de Biología, Universidad Nacional Autonoma de Mexico, Mexico*
Coastal ecosystems in the southern Gulf of Mexico are continuously under various anthropogenic pressures, some associated with agricultural activities in the region, where organochlorine pesticides (OCPs) are still applied. This study aimed to record the current presence of these compounds in sediments and identify the influence of organic matter content and grain size on their distribution. Using standardized gas chromatography with mass spectrometry (GC/MS/MS) methods, seven of 16 pesticide residues (44%) were quantified in sediments, with endrin aldehyde being the most abundant compound; the recent entry of p,p'-DDT was also highlighted. Spearman's correlation matrix and principal component analysis (PCA) found that these pesticides' accumulation and spatial distribution in sediments were associated with fine grain size. The environmental risk assessment using the Sediment Quality Guidelines (SQGs) determined that ecotoxicological effects would occasionally be observed in the benthos. This information is complemented with additive risk quotients, suggesting that the presence of OCPs represents a low to moderate level of risk, mainly due to p,p'-DDT, and dieldrin, the latter with the most alarming individual risk quotients. The data obtained in this work could contribute to public policy actions focused on mitigating and preventing the ecosystem risk from these compounds to achieve integrated management of the anthropogenic activities carried out in this Mexican coastal lagoon.

Disclaimer/Disclosure: None of the authors have relevant financial or non-financial interests to disclose. This research received grants from the Dirección General de Asuntos del Personal Académico (DGAPA), UNAM, from field sampling to laboratory analyses, within the commitments of the PAPIIT IN214620 project Highly hazardous pesticides in organisms of importance fishing in the Alvarado Lagoon System, Veracruz.

4.11.P Marine and Coastal Pollution: Novel Quality Assessment Strategies and Management

4.11.P-We346 Exploring the Distribution and Impacts of Chemical Pollution in Coral Reef Ecosystems

Milo Leon de Baat, *Nienke van de Loosdrecht and Jasper de Goeij, Department of Freshwater and Marine Ecology (FAME), Institute for Biodiversity and Ecosystem Dynamics (IBED), University of Amsterdam, Netherlands*

Coral reef ecosystems are some of the most biodiverse and valuable ecosystems on the planet. Yet, they are threatened by a combination of local and global stressors, and coral reefs have been declining rapidly since the 1950s. The effects of climate change, like rising seawater temperatures and ocean acidification, as well as local impacts from eutrophication on coral reefs, are well-studied. However, the effects of the complex mixtures of water-borne substances and chemical pollutants on the health of corals (e.g., their reproduction, settlement, and growth) and reef ecosystems (e.g., structural integrity and functioning) are remarkably poorly understood. Moreover, water quality is rarely assessed before restoration efforts. This is surprising, as water quality (i.e., beyond eutrophication) is a major driver of coral reef health, alongside the detrimental impact of climate change effects. In addition to improving restoration and conservation success, coral reef water quality assessment can guide stressor management at a local scale, unlike global climate change effects. Many water quality assessment methods are available, mostly in the context of freshwater systems, but an impact assessment of complex chemical mixtures on coral reefs has not been established. Hence, there is a need for an effective and integrated water quality assessment method for the protection of coral reefs.

The combination of time-integrative sampling, advanced chemical analyses, and effect-based methods has seen rapid development for the impact assessment of complex chemical mixtures in aquatic ecosystems. We aim to tailor these methods to the particular requirements of coral reef environments to establish an effective water quality assessment strategy. Passive sampling was applied with in situ flow monitoring to obtain quantitative and representative chemical mixtures from bays and adjacent coral reefs in the Southern Caribbean. Passive sampler extracts were analyzed using chemical target- and non-target analyses to gain insight into the anthropogenic chemical diversity, identity, and distribution. Effect-based methods were applied to quantify mixture toxicity and gain insight into the toxic effects of chemicals across the coral ecosystem. This poster summarizes multiple years of research to discuss and guide the establishment of a future-proof coral reef water quality monitoring framework.

4.11.P-We347 Impacts of Chemical Pollution on Biodiversity and Biological Responses in the Archipelago Sea (Baltic Sea)

Raisa Turja[1]*, Anna Reunamo*[2]*, Ivan Kuprianov*[3]*, Milda Stankeviciute*[4]*, Janina Pazusiene*[4]*, Ksenia Pazdro*[5]*, Marcelina Ziolkowska*[5]*, Riikka Puntila-Dodd*[2]*, Joachim Sturve*[6]*, Rami El Dairi*[1]*, Ossi Tonteri*[1] *and Kari K. Lehtonen*[2]*, (1)Finnish Environment Institute (SYKE), Finland, (2)Finnish Environment Institute (Syke), Finland, (3)Tallinn University of Technology, Estonia, (4)Nature Research Centre, Lithuania, (5)Institute Of Oceanology, Poland, (6)University of Gothenburg, Sweden*

Biodiversity is vital for the structure and function of marine ecosystems but is increasingly threatened by chemical pollution, a major driver of global biodiversity loss. This study investigated the effects of chemical pollutants on marine wildlife by combining sediment contamination analysis with biochemical biomarkers in the bivalve *Macoma balthica*, as well as biodiversity indicators including species composition and environmental DNA (eDNA) analysis.

In August 2024, a field sampling campaign was conducted targeting a well-characterized pollution gradient in the Archipelago Sea, northern Baltic Sea. Sediment samples were collected from five stations ranging from a pristine reference site in the outer archipelago to highly polluted inner stations. Biodiversity was assessed through benthic fauna surveys and eDNA analysis of sediment samples. Stable isotope analysis of carbon and nitrogen will be performed to investigate trophic interactions and potential shifts in food web structure along the pollution gradient. Additionally, sediment samples were analyzed for chemical contaminants and physicochemical properties. Specimens of *M. balthica* were collected from each station, with their tissues analyzed for oxidative stress biomarkers, neurotoxicity, genotoxicity, cytotoxicity, and a condition index to evaluate biological effects.

Macrofaunal diversity declined along the pollution gradient, with sensitive species such as *Monoporeia affinis* likely restricted to the reference site, while tolerant species like *M. balthica* persisted across all stations. eDNA analysis is expected to show reduced genetic diversity and shifts in meiofaunal communities at polluted sites, highlighting ecosystem-level impacts. Stable isotope analysis is anticipated to reveal altered trophic structures and disrupted energy transfer in contaminated areas, while markedly increased biological effects are expected in *M. balthica* from the most polluted sites.

The integration of biomarker responses, contaminant levels, stable isotope data, and biodiversity indicators is expected to demonstrate clear links between chemical pollution and changes in biodiversity. These findings will highlight the need for multistressor approaches to better understand and address the complex impacts of pollution on marine ecosystems.

4.11.P-We348 Metals in Squids (*Doryteuthis sanpaulensis*) from the Cananéia-Iguape Estuarine-Lagoon System (SP), Brazil

Esther Calochorios Litvac *and Tailisi Hoppe Trevizani, Oceanographic Institution of the University of São Paulo, Brazil*

Human occupation in coastal areas is accompanied by several activities that are sources of pollution, including metals, potential toxic elements that can accumulate in organisms, presenting risk to animal health and, in the case of commercial species, to human health. The Cananéia-Iguape estuarine-lagunar system is a region with a history of contamination, mainly due to mining and agriculture, which is currently considered a Natural World Heritage and a RAMSAR site and its main economic activity is fishing. The objective of this study is to analyse the levels of heavy metals (As, Cd, Cr, Cu, Ni, Pb and Zn) in squids in order to compare them to the levels established in the legislation for human consumption and verify whether their consumption affects food security. A total of 64 squid samples were obtained with local fishermen in the city of Cananéia. In the laboratory, they were measured and weighted wet and the metals were extracted according to the methodology described by Trevizani et al. (2016) and analysed by Inductively Coupled Plasma Optical Emission Spectrometry and Mass Spectrometry (ICP-OES and ICP-MS). Ni was not detected. As ranged between 0,060 and 0,649 mg kg -1; Cd ranged between 0,042 a 0,390 mg kg -1; Cr presented values between 0,072 and 1,004 mg kg -1; Cu was between 1,614 and 25,724 mg kg -1; Pb ranged between 0,1 and 13,907 mg kg -1 and Zn ranged between 5,024 and 27,344 mg kg -1. These results were compared with the values established by the Brazilian (ANVISA, 1965, 2013) and international (FAO, 1983, 2017) legislation. It was noted all metals were at levels below those established by legislation except for chromium, three lead samples and one arsenic sample. Correlation analysis showed significant and positive relations between As and Cd with weight and length, which corroborates with studies indicating a high bioaccumulation of the latter in squids. The lack of evidence of contamination of metals in the squids studied suggests that this resource has a great food potential, as it does not pose a health risk. Furthermore, this was a pioneer study on squids in the region, allowing biomonitoring of metals and assessment of the quality of fishing resources, contributing to public health and serving as a basis for decision-making aimed at a better management and conservation of this area.

Disclaimer/Disclosure: The present study is associated with and supported by the FAPESP Regular Research Project nº 2024/04284-8 "Metals in Fish: Environmental Monitoring and Food Safety in the Marine Environmental Protection Areas of the State of São Paulo, Brazil."

4.11.P-We349 Occurrence, Concentration, and Risk Assessment of Phthalates in Commercial Fish Species from the Italian Coast

Andrea Maccantelli[1]*, Matteo Galli*[2]*, Margherita Concato*[2]*, Dario Giani*[2]*, Cristina Panti*[1]*, Maria Cristina Fossi*[1] *and Matteo Baini*[1]*, (1)Department of Physical Science, Earth and Environment, University of Siena; National Biodiversity Future Center, Italy, (2)Department of Physical Science, Earth and Environment, University of Siena, Italy*

Phthalate esters (PAEs) are contaminants of concern due to their widespread use and potential release into the environment. Despite their extensive use, assessment of PAEs occurrence, bioaccumulation and adverse health effects in marine organisms and humans are limited. This study aims to quantify PAEs levels in commercially important fish species across multiple trophic levels, and habitats, collected in six sampling sites along the Italian coast (Northern, Central, and Southern Adriatic Sea; Sardinian Sea; Ligurian Sea; and Tyrrhenian Sea). The aim of this study is to ascertain the concentrations of PAEs in diverse population groups potentially exposed to PAEs and to evaluate the level of pressure across the various sampling site under examination. A a follow-up objective of this study is also to evaluate the potential impact of fish consumption on human health. The levels of 11 PAEs of environmental relevance (DMP, DEP, DAP, DPrP, DIBP, DBP, BBzP, DChP, DEHP, DINP and DNOP) were evaluated in the muscles of eight fish species. Regarding the risk assessment for human comsumption the Hazard Quotient (HQ) and Life Time Cancer Risk (LTCR) index were evaluated. The results show that PAEs are widespread in the selected areas and species, in particular, DBP, DEHP, and DIBP are the most concentrated and present compounds representing more than 80% of the total ?PAEs in all species and areas, with an occurrence above the 90%. *Sardina pilchardus* exhibiting the highest values detected among the sampling sites investigated. Otherwise, the analysis of sampling sites showed a smaller number of differences, which may indicate the widespread distribution of these contaminants across all the areas under investigation. As concern the risk assessment for human health, results showed that the consumption of the fish species analysed does not pose a risk to humans. Hazard quotients were lower than 1 in all scenarios and the LTCR was below the threshold of unacceptable risk. The known endocrine disrupting properties of the identified PAEs and the commercial value of the species analysed highlight the need for additional studies to better understand the potential impact on the organisms, the food web and humans.

Disclaimer/Disclosure: The authors thank the National Recovery and Resilience Plan (NRRP), Mission 4, Component 2 Investment 1.4 - Call for tender No. 3138 of 16 December 2021, rectified by Decree n.3175 of 18 December 2021 of Italian Ministry of University and Research funded by the European Union NextGenerationEU (Award Number: Project code CN_00000033, Concession Decree No. 1034 of 17 June 2022 adopted by the Italian Ministry of University and Research, CUP D33C22000960007, Project title National Biodiversity Future Center - NBFC).

4.11.P-We350 Plasticizer Contamination in Commercially Important Fish Species from the Mediterranean Sea: Assessment of Potential Tisk to Human Health

***Chiara Dettoto**[1], Andrea Maccantelli[2], Maria Vittoria Barbieri[3], Matteo Baini[2], Julio Fernandez-Arribas[3], Cristina Panti[2], Dario Giani[1], Matteo Galli[1], Ethel Eljarrat[3] and Maria Cristina Fossi[2], (1)Department of Physical Science, Earth and Environment, University of Siena, Italy, (2)Department of Physical Science, Earth and Environment, University of Siena; National Biodiversity Future Center, Italy, (3)Environmental and Water Chemistry for Human Health group (ONHEALTH), Institute of Environmental Assessment and Water Research (IDAEA-CSIC), Spain*

Plastic materials contain a wide variety of additives which are not covalently bound to their structures, such as phthalic acid esters (PAEs), organophosphate esters (OPEs), and non-phthalate plasticizers (NPPs),which are easily released into the environment, affecting marine ecosystems. These additives can interact with marine organisms, including commercially important fish species such as bogue (*Boops boops*), European hake (*Merluccius merluccius*), red mullet (*Mullus barbatus*), and European pilchard (*Sardina pilchardus*). High fish consumption would increase human exposure to these compounds due to potential bioaccumulation in fish edible tissue. The limited studies focused on the occurrence of plastic additives in those Mediterranean fish species, and on the potential health risks associated with fish ingestion, highlights the need to deep into study.

The aim of this study was to assess the presence and concentration of PAEs, OPEs, and NPPs in the muscles of bogue, European hake, red mullet, and European pilchard, collected from the Ligurian Sea and Central Adriatic Sea (Mediterranean Sea). PAEs were analyzed with ultrasound assisted extraction (UAE) and dispersive solid-phase extraction (d-SPE), followed by GC-MS analysis. OPEs and NPPs were extracted using UAE and measured with a Turbulent Flow Chromatography (TFC) purification system coupled to LC-MS/MS. In addition, the potential risk to human health from fish consumption was assessed to determine whether the levels found could potentially be of concern for human health.

PAEs were the predominant additives detected, with a similar distribution across both study areas. Among PAEs, bis(2-ethylhexyl) phthalate (DEHP) (156±100 ng/g wet weight), dibutyl phthalate (DBP) (87.7±76.3 ng/g ww), and diisobutyl phthalate (DIBP) (79.5±71.3 ng/g ww) were the most abundant. Triethyl phosphate (TEP) (21.4±7.88 ng/g ww) and acetyl tributyl citrate (ATBC) (1.12±0.98 ng/g ww) were the OPE and NPP most abundant detected, respectively. A risk assessment based on median and 95th percentile fish consumption levels showed no significant health risks for humans (Hazard Quotient<1), although some Life Time Cancer Risk values for DEHP for the youngest part of the population approached threshold limits.

These findings will contribute to fill the gaps regarding the presence of these additives in marine fish, highlighting further research is necessary to monitor a potential human risk via fish consumption.

4.11.P-We351 Signatures of Exposure to Persistent Organic Pollutants in Mesopelagic Fish from Northern California Current Ecoregion

***Miguel Vasquez**[1], Zuying Feng[1], Damian Shea[2], Claire Willaredt[3] and Goran Bozinovic[1], (1)Boz Life Science Research and Teaching Institute, United States, (2)Statera Environmental Inc, United States, (3)Portland State University, United States*

Global biodiversity is increasingly compromised by human activities, and understanding ecological consequences of these disturbances is critical for conservation policy decisions and impact mitigation efforts. While waste such as sewage and plastic trash constantly enter the marine environment, more than 80% of the ocean is still unexplored, let alone examined for pollution impact. At 200 to 1000 meters below the surface, the ocean mesopelagic zone is characterized by episodic sinking of organic matters and migrating animals that retreat from illuminated levels during the day. This dynamic environment provides a unique opportunity for ecological assessment of potential hazardous chemical exposure. We targeted 135 organic pollutants in the livers of viperfish, owlfish, and lanternfish captured from 400 to 800 meters deep near the Oregon coast using high-performance gel permeation chromatography and gas chromatography mass spectrometry. Among the 52 compounds detected above the quantification limit, polychlorinated biphenyls (PCBs) are the most abundant type of chemicals, followed by pesticides, brominated flame retardants (BFRs), and phthalates. The most concentrated pollutant is a PCB, Cl6 (153) at 3.70 ng/g, and the highest total concentration of PCBs in a liver is 21.85 ng/g, both detected in lanternfish. Besides PCBs, many pesticides on the Stockholm Convention's Persistent Organic Pollutants list were also detected, including aldrin, dieldrin, lindane, mirex, dichlorodiphenyltrichloroethane (DDT), and hexachlorobenzene (HCB). Although none of the 49 targeted current-use pesticides were detected, 21 of the 25 legacy organochlorine pesticides were detected, highlighting their persistence. The most abundant BFR is PBDE-17, with the highest concentration of 2.60 ng/g in lanternfish. Overall, lanternfish livers tend to contain more pollutants, likely due to their diel vertical migration that exposed them to surface-level pollution. Bis(2-ethylhexyl) phthalate (DEHP) is the only detected and one of the most used phthalates, and it was only detected in viperfish. Despite being in the largest solution on Earth and hundreds of meters from the surface, mesopelagic fish are not spared from exposures to hazardous anthropogenic pollutants. The ocean has been historically treated as a convenient sink for waste, and our data highlights that disposed persistent organic pollutants remained a looming threat to the marine ecosystem.

4.11.P-We352 Potential Risk Assessment of Microplastics Ingestion by Some Commercial Fish Species in the Northern Oman Sea, Iran

Mahsa Mobasheri[1]*, Mohammad Javad Nematollahi*[2]*, Tooraj Valinassab*[3]*, Lobat Taghavi*[4]*, Hassan Nasrollahzadeh Saravi*[5] *and Alina Astefanei*[6]*, (1)Department of Environmental Science and Forest, Science and Research Branch, Islamic Azad University (SRBIAU) & Van 't Hoff Institute for Molecular Sciences, Faculty of Science, University of Amsterdam, Netherlands, (2)Department of Geology, Faculty of Sciences, Urmia University, "Iran, Islamic Republic Of", (3)Iranian Fisheries Science Research Institute (IFSRI), Agricultural Research Education and Extension Organization (AREEO), Tehran, Iran, "Iran, Islamic Republic Of", (4)Department of Environmental Science and Forest, Science and Research Branch, Islamic Azad University (SRBIAU), "Iran, Islamic Republic Of", (5)Caspian Sea Ecology Research Center, Iranian Fisheries Science Research Institute (IFSRI), Agricultural Research, Education and Extension Organization (AREEO), "Iran, Islamic Republic Of", (6)Van t Hoff Institute for Molecular Sciences (HIMS), University of Amsterdam, Netherlands*

Nowadays, microplastics (MPs) are emerging as a global contaminant, have attracted significant research attention. This study investigates the occurrence, abundance, and characteristics of microplastics in the gills, gastrointestinal tract (GIT), and skin of three commercial fish species (*Psettodes erumei*, *Sphyraena putnamae*, and *Ephippus orbis*) from the northern Oman Sea. It aims to provide baseline data for potential ecological risk assessment, conducted for the first time in this region. A total of 784 microplastic particles were identified across all tissues examined. These MPs were characterized based on their physicochemical attributes using a stereomicroscope and Raman spectroscopy. The results showed that fibers were the most prevalent shape, and blue was the dominant color. Predominant MPs ranged in size from 200-500 µm. Polypropylene (PP) and Polyvinyl chloride (PVC) were the most common polymers detected. Risk assessment using the polymeric hazard index (PHI) was utilized to verify the hazard level of identified polymers. The overall hazard level of MP pollution was categorized I to II which poses minor to medium risks respectively. The findings of this study not only highlight the widespread nature of microplastic contamination in the study area but also provide critical baseline data. Moreover, given the potential effects of MPs on human health, fish consumers with high intake may face health risks which require further investigation.

4.11.P-We353 Comparison of Species Sensitivity Distribution Modeling Approaches for Assessing Risk of Microplastic Particles using Monitoring Data from Tokyo Bay

Wataru Naito*, Koji Ueda and Yuichi Iwasaki, Research Institute of Science for Safety and Sustainability,*

National Institute of Advanced Industrial Science and Technology, Japan
In recent years, the impact of microplastics (MPs) on marine ecosystems has become a growing concern, attracting attention from governments, society, and researchers around the world. This increased awareness has led to a rise in studies on MPs in the marine environment, including monitoring their occurrence, understanding their behavior and fate, developing analytical methods, and examining their effects on ecosystems and organisms. Despite these advancements, there remains a critical gap in quantitative assessments that are essential for formulating effective, risk-based management strategies tailored to real-world scenarios. One promising approach to address this gap involves the assessment of ecological risks posed by MPs using species sensitivity distributions (SSDs). While significant progress has been made in generating toxicity data and monitoring smaller-sized MPs, the lack of standardized methodologies continues to hinder efforts, introducing substantial uncertainties in risk assessments. To address this, the present study utilizes comprehensive microplastic monitoring data from Tokyo Bay, combined with SSDs derived through multiple approaches such as a Bayesian modeling, to quantify ecological risks. Additionally, this study explores how variations in MP size classifications and differences in key assumptions influence the outcomes of these risk assessments, providing valuable insights into improving the robustness and reliability of future risk assessment frameworks with SSDs.

4.11.P-We354 'NurdleTrack' – Source Identification and Hazard Assessment of Marine Plastic Nurdle Spills

*Lisbet Sorensen[1], Amaia Igartua[1], Bjorn Henrik Hansen[1], Sam Durrance[1], Synnove Lofthus[3], Marta Panero[1], Silje Berger[3], Duarte Soares[1], Kristin R. Sorheim[2] and **Andy Booth, PhD**[2], (1)SINTEF Ocean, NTNU, Norway, (2)ITOPF, United Kingdom, (3)Norwegian Coastal Administration, Norway*
Unintentional spills of plastic nurdles from shipping containers represent the second largest source of primary microplastic to the marine environment, with an estimated annual release of >200 kTons. Given their high production volumes and natural buoyancy, polyolefins (PE and PP) are unsurprisingly the most commonly found nurdle types on beaches. With the increasing focus on nurdles as a potential environmental hazard, source identification, chemical hazard assessment, and the development of effective spill response are crucial processes.
With NurdleTrack, we offer analytical chemical tools that can simultaneously address both source identification and hazard assessment within a short response time. A multi-tiered fingerprinting approach is presented, utilizing physical characteristics followed by thermal desorption and pyrolysis GC-MS in combination with multivariate statistics to robustly assess the source of field-collected nurdles derive from any suspect source of pollution or spill event. Chemical composition determined from the same screening is further subject to in silico hazard assessment based on a combination of experimental and modelled physico-chemical and toxicological properties obtained from open-source databases.
Verification of the proposed pipeline through field and laboratory assessments will be presented. We have successfully applied the chemical fingerprinting protocol to four previous nurdle spill events (South Africa 2017 and 2020, Trans Carrier Norway 2020, Xpress Pearl Sri Lanka 2021). Validation of the hazard assessment protocol using a combination of predicted and observed toxicity of commercial and field-collected nurdles (from the Galicia spill in 2023) towards a model test species (marine microalgae Skeletonema costatum) and an inter-tidal test species (Common periwinkle, Littorina littorea) is further presented. The impact of UV-degradation on the fate and toxicity of polyolefin nurdles is assessed through accelerated degradation in the laboratorty and compared to field-collected samples that have been in the environment for an extended period of time. This is critical for understanding how material changes can be integrated into source identification and to understand how response approaches can mitigate environmental impacts.

4.11.P-We355 Application of a Matrix Scoring Technique: A Reliable Methodology for the Sourcing of Macrolitter from River-Sea Interfaces?

***Therese Nitschke**[1], Camille Camille[2], Gita Maas[3], Perrine Guillemenot[2], Marine Paul[2], Silke De Buyser[1], Lisa Inès Devriese[4] and Ana I Catarino[1], (1)Flanders Marine Institute (VLIZ), Belgium, (2)CEDRE Centre de Documentation, de Recherche et d Experimentations sur les Pollutions Accidentelles des Eaux, France, (3)Stichting De Noordzee, Netherlands, (4)Ocean & human health, Flanders Marine Institute (VLIZ), Belgium*
Marine litter and plastic pollution are a major concern and prominent topic in public discourse, science and governance. Global efforts to reduce anthropogenic litter require information about the emission sources to effectively mitigate the problem. While the scientific community seems to agree most sources are land-based and enter the ocean via sewers, stormwater overflows and rivers, there are significant

uncertainties in the quantification and identification of the sources due to the lack of established and standardised methodologies. In this work, we present how a Matrix Scoring Technique, first introduced by Tudor & Williams (2004) and adjusted by CEDRE (France), is applied as harmonised method in the TREASURE (Targeting the REduction of plAStic oUtflow into the noRth sEa) project to assess macrolitter pollution in river-sea interfaces. Our goal was to compare the sources of riverine and marine litter from the riverbanks and beaches in the area of the Yser estuary in Belgium. A source is defined here as the activity or sector that released the litter in the environment, e.g. fishing, tourism, buildings and constructions. Both the riverine and marine macrolitter batch were sorted and classified according to the Joint List of Litter Categories for Marine Macrolitter Monitoring (J-List). Each litter category was allocated to its potential source by assigning probability ratios to the entirety of all predefined source options. The developed likelihood matrix delivers an estimate of the contribution of each source activity. Each contribution was proportionally assessed, giving insights into the main sources and how they change from inland to the North Sea. A preliminary assessment indicated that the major contributions to riverine litter were from coastal tourism and recreation, hunting, and buildings and constructions whereas the beach litter was associated with coastal tourism and recreation, fish and shellfish fishing, and hunting. With the application of the Matrix Scoring Technique, we are not only applying an innovative methodology to the complex problem of litter pollution but also creating a knowledge basis for further support towards targeted governance and legislation, including the evaluation of the effectiveness of policy measures. The identification of sources is determining for the design of policies that help create safe, sustainable, and litter-free environments for current and future generations.

4.11.P-We357 Assessment of Sediment Neurotoxicity Through Effect-Based Methods: A Case Study in a Lagoon in Central Italy

Ines Lacchetti[1]*, Valentina Pantano*[2]*, Kevin di Domenico*[1] *and Mario Carere*[1]*, (1)Environment and Health, Italian National Institute of Health, Italy, (2)Italian National Institute of Health, Italy*

The quality of sediments in coastal lagoons is a critical environmental concern, as they can act as reservoirs for several persistent contaminants that threaten aquatic ecosystems and human health. These pollutants may originate from anthropogenic activities and natural processes and can be transferred in the foodchain. For several substances (e.g. mercury) neurotoxicity represents an important mode of action. This study investigates the neurotoxic potential of sediments from a Lagoon in Central Italy, integrating in vivo assays and biomarkers to assess the potential impact on aquatic organisms. Sediment sampling was carried out in areas of the lagoon where methylmercury was already known to be present at different concentrations in the biota. Sediment elutriates were analyzed using a behavioral assay on Artemia salina larvae, employing an internal laboratory method to evaluate locomotor responses, including swimming speed, distance covered, and phototactic preferences when exposed to sediment samples. Additionally, acetylcholinesterase (AChE) activity was measured in Anguilla anguilla specimens captured from the lagoon to assess potential neurotoxicity at the enzymatic level. Preliminary results indicate alterations in behavioural parameters of Artemia; these findings seem to show the presence of neurotoxic contaminants in lagoon sediments. This study highlights the importance of integrating behavioral and biochemical endpoints to evaluate the ecological risk of sediment-associated pollutants in lagoon environments emphasizing the need for continued monitoring and targeted efforts to protect these vulnerable habitats.

4.11.P-We358 Spatial Distribution of PAHs, Ni, and V, and Ecotoxicological Risk Estimation in Sediments from Terminos Lagoon Located Near a Petroleum Extraction Area in the Southern Gulf of Mexico

Hugo F. Olivares Rubio[1]*, Jorge Feliciano Ontiveros-Cuadras*[1]*, Guadalupe Ponce-Velez*[1]*, Laura Salazar-Remigio*[2] *and Víctor Gabriel Elías-García*[2]*, (1)Unidad Academica de Procesos Oceanicos y Costeros, Instituto de Ciencias del Mar y Limnolog a, Universidad Nacional Autonoma de Mexico, Mexico, (2)Posgrado en Ciencias del Mar y Limnolog a, Instituto de Ciencias del Mar y Limnolog a, Universidad Nacional Autonoma de Mexico, Mexico*

The Terminos Lagoon, a Ramsar site, covers approximately 7060 km2, is located adjacent to the Cantarell oil field in Campeche Sound, and is connected to the Southern Gulf of Mexico Marine Ecoregion. The objectives of this study were to determine the concentration of 16 priority polycyclic aromatic hydrocarbons (PAHs), Ni, and V in surface sediments, infer their emission sources using diagnostic ratios of PAH isomers and Ni-V, and estimate the ecotoxicological risk using the Mean Effect Range Medium Quotient (M-ERM-Q) of the three most frequent PAHs (naphthalene, phenanthrene, and benzo[a]pyreno) and Ni in sediments. PAHs ranging from 3.1 to 248.9 ng g^{-1}, Ni = 11.0-104.0 mg kg^{-1}, and V = 2.0-35.0

mg kg^{-1} dry weight. PAHs levels were lower than in other coastal lagoons from the litoral of the southern Gulf of Mexico. PAHs were correlated to organic matter contents, and metal accumulation depended on the input of lithogenic materials. PAHs indices and metal concentrations did not indicate crude oil pollution in the area, probably due to the high hydrodynamic of the marine region of the southern Gulf of Mexico; however, pyrogenic sources of PAHs were noted. The greatest PAHs levels were detected in a site highly impacted by anthropogenic activities due that it is located in Ciudad del Carmen, the biggest urban center of the region. Ecotoxicological risk assessments pointed to an elevated risk of adverse effects in sites near swamps and mangrove zones, emphasizing the importance of continued monitoring due to the high biodiversity of these ecosystems. This research offers valuable guidance for policymakers aiming to protect the largest coastal lagoon in Mexico, the Terminos Lagoon, and other oil-affected coastal regions worldwide.

Disclaimer/Disclosure: Financial support was provided by the project PAPIIT-DGAPA IN115023 from the Universidad Nacional Autónoma de México (UNAM). We extend our gratitude to Francisco Ponce Núñez and Victor Gabriel Elías García for their assistance in the creation of figures and the PCA analysis using R software, as well as to Arturo Ronquillo Arvizu for his technical support.

4.11.P-We359 Polycyclic Aromatic Hydrocarbons during the 21st Century in Southern Gulf of Mexico, a Prominent Petroleum Area: A Review and Risk Estimation

Hugo F. Olivares Rubio *and Guadalupe Ponce-Velez, Unidad Academica de Procesos Oceanicos y Costeros, Instituto de Ciencias del Mar y Limnolog a, Universidad Nacional Autonoma de Mexico, Mexico*

In the Southern Gulf of Mexico Marine Ecoregion (SGoME), the petroleum industry was started in 1950. Campeche Bay is notable for the presence of petroleum hydrocarbons attributed to natural seeps and oil spills. On the other hand, in several transitional waters in the SGoME, anthropogenic activities could release hydrocarbons into these environments. The objectives of this study were to present the status of polycyclic aromatic hydrocarbons (PAHs) pollution in the transitional and marine waters of the SGoME during the 21st century and estimate the ecotoxicological risk in sediments. Using a systematic search in Google Scholar, we compiled 34 published research articles and book chapters from 2000 to 2024 about the concentration of PAHs in water, sediments, and aquatic biota in the region under study. We estimate the risk quotient based on the maximum permissible concentration (RQ MPC-16PAHs) and effect range median for PAHs in sediments. The interval of PAHs concentration in water detected was from 0.001 ng L-1 in La Pesca Lagoon to 370 ng L-1 from Mecoacán Lagoon. PAHs levels in sediments were higher in Sontecomapan, Mandinga, and La Mancha Lagoons in the Veracruz State, which were more significant than in other areas worldwide. The American oyster was the most studied aquatic organism for PAHs concentration in the SGoME, whose concentration interval was from 75.2 (Alvarado Lagoon System) to 5672 ng g-1 (Terminos Lagoon), suggesting a difficult situation, which may imply a possible human health risk. RQ MPC-16PAHs values showed that Mecoacán Lagoon, the Coastal shelf Tamaulipas, and Cayo Arcas Reef Complex were the three sites with the highest values from the maximum concentration detected in these sites. Veracruz State possesses the highest frequency of values higher than 1 for the RQ MPC?16PAHs. Implementing monitoring programs for PAHs is crucial to safeguard environmental and human health in petroleum regions with several sources of these pollutants.

Disclaimer/Disclosure: Financial support was provided by Instituto de Ciencias del Mar y Limnología UNAM, Project number 218 Petrochemical activity and climate change impacts in the littoral of Gulf of Mexico. We extend our gratitude to Francisco Ponce Nuñez for his assistance in the creation of figures.

4.11.P-We360 Environmental Risk Assessment Associated with the Discharge of Subsea Pipeline Contents Between Oil Extraction Platforms

Walter D. di Marzio*, Maria Elena Saenz, Santiago Martinez and Jose Alberdi, PRIET DCB UNLU CONICET, Argentina*

This study focuses on the environmental risk assessment of the discharge of contents from a subsea pipeline connecting oil extraction platforms. The pipeline contents consist of seawater and minimal amounts of a corrosion inhibitor dosed at an initial predetermined concentration. The evaluation includes an analysis of studies on the fluid's hazard estimation, a four-year degradation test of the product, physicochemical analysis of the mentioned solution, and modeling and simulation of the discharge dilution in the receiving environment. These data are further compared with the results of ecotoxicity tests conducted on both the initial solution and the degraded solution as estimated in the decay study, before and after biodegradability tests. This approach addresses all possible scenarios of environmental exposure for aquatic organisms, thereby reducing uncertainty in estimating the environmental risk associated with the release of the pipeline contents into the surrounding marine environment. Three risk analysis scenarios are applied, based on the concept of toxic units and species sensitivity distribution (SSD) curves, under two possible impact scenarios. Considering the worst-case discharge scenario with a specific product concentration and using the LC/EC50 value for the most sensitive species, toxic unit values are calculated as a function of dilution, factoring in pumping flow rate and ambient current velocity. Alternatively, the study considers the decline in concentration due to degradation within the pipeline during the accumulation period, providing a contrasting concentration for the SSD analysis.

4.11.P-We361 Offshore Chemical Regulatory System & Risk Assessment
Kirit Wadhia, *NOV, United Kingdom*
Introduction: Protection of the marine environment from the discharge of chemicals used offshore is of global importance. Sustainable operations in the oil and gas sector requires a regulatory framework ensuring protection of the ecosystem and prevention of deleterious environmental impact.
Chemicals use and discharge for petroleum exploration activities in the OSPAR region require chemicals to be registered via the OSPAR s Harmonised Mandatory Control System (HMCS). The objective of the HMCS is to protect the marine environment by identifying those chemicals used in offshore oil and gas operations with the potential for causing an adverse environmental impact and restricting their use and discharge to the sea. Thus, for the chemical supply industry there is pressure to develop products that comply and fulfil technical performance and environmental risk criteria, Operators (oil companies) requirements are more linked to ensure optimum operational performance.
On the environmental regulatory front Recommendation 2012/5 requires Contracting Parties to implement a risk-based approach (RBA) for the management of produced water discharges from offshore installations. RBA utilises a stepwise screening tiered approach involving either whole effluent toxicity and/or substance -based approach with use of dispersion modelling to establish if chemical discharges are likely to result in adverse effects to the marine environment.
Does this approach regarding methodology and regulatory framework criteria address the evaluation of potential combined effects of chemicals? Does the regulatory implementation require field monitoring to assess the impact on the ecosystem?

4.11.P-We362 The Effects of Water Accommodated Fraction from Chemically Dispersed Marine Gas Oil on the Lipid and Astaxanthin Profiles of the North Atlantic Copepod Calanus finmarchicus
*Tamer Amr Hafez[1], **Belen Gonzalez-Gaya**[1], Maren Ortiz-Zarragoitia[1], Dag Altin[2], Bjorn Munro Jenssen[3] and Tomasz Ciesielski[4], (1)University of the Basque Country, Spain, (2)BioTrix, Trondheim, Norway, (3)NTNU, Norway, (4)UNIS, Svalbard, Norway*
Copepods are key members of the zooplankton communities. Through their diets, some copepods species accumulate the carotenoid astaxanthin and lipids, which both are beneficial for copepods. For example, astaxanthin has antioxidant and anti ultra-violet radiation properties. Astaxanthin can also be extracted to be commercially used as an antioxidant supplement for human consumption. Additionally, lipid accumulation is crucial for the copepod s wellbeing and for surviving diapause during winter. However, little research is available on how copepods can utilize the astaxanthin properties to protect against pollution stress or how pollution can affect astaxanthin and lipids incorporation in copepods. Therefore, the objective of this study was to investigate the how environmentally relevant pollution, can influence lipid and astaxanthin accumulation and metabolism in the cold water copepod Calanus finmarchicus. The selected pollutant used in this study was a Marine Gas Oil Water Accommodated Fraction mixed with a commercial dispersant: Finasol OSR 52 (MGO CEWAF). Adult copepods were exposed for 96 hours to 4.22% MGO CEWAF. Pools of the exposed copepods were taken at 0, 24, 48, 72 and 96 hours post-exposure. The profiles of the astaxanthin and lipids were measured in pools of 10 copepods using high-resolution Mass spec orbitrap (HR-MS orbitrap). The astaxanthin profile in both exposed and non-exposed copepods was mostly dominated by monoesters (>95%), followed by free form Astaxanthin (2-4%), and diester forms (>1%). With respect to the two most abundant monoesters (C16:0 & C18:1), both showed the same dynamics throughout the experiment: Slight increase in the experimental groups (exposed and non-exposed) after 24 hours. In the the control group, compared to the concentrations at 24 hours, there was a significant decrease in the concentration of the astaxanthin after 96 hours. This decrease overtime in the non-exposed group could be due to the breakdown of the monoester astaxanthin due to starvation. On the other hand, in the exposed group, no significant changes in the concentration of the monoesters occurred throughout the experiment. This indicate that the exposure to MGO CEWAF disrupted the breakdown dynamics of the monoesters as a function of exposure time. However, the upcoming lipid profile results will further demonstrate the dynamics between astaxanthin accumulation during exposure and lipid metabolism and accumulation in Calanus finmarchicus.

Disclaimer/Disclosure: This work has been funded by the HORIZON 2020 GRACE project. T.H is a holder of Margarita Salas postdoctoral fellowship in UPV/EHU, funded by European Union-Next Generation EU. BGG acknoledges a 2024 IkerBasque fellow tenure track.

4.11.P-We363 Fourth Generation Oil Spill Dispersants Applied on Patagonian Petroleum Spills

***Walter D. di Marzio**, Maria Elena Saenz, Santiago Martinez and Jose Alberdi, PRIET DCB UNLU CONICET, Argentina*

The final formulation proposed as fourth-generation dispersants was developed. We considered the applications of dispersant formulations, aiming to achieve an optimal combination of compounds based on three key characteristics, which also served as control parameters: efficacy, biodegradability, and ecotoxicity.

The new dispersants were tested on the following types of crude oil extracted from Patagonian wells in Argentina: Caleta Córdoba, Caleta Olivia, Hydra Total, and Cruz del Sur YPF. Their performance was compared with that of other commercial dispersants.

Dispersants are specially designed mixtures for oil spill response, composed of detergent-like surfactants dissolved in various organic solvents. While dispersants do not remove oil from water, they work by breaking the oil into small droplets, facilitating natural degradation processes.

After application, the aquatic phase was evaluated for ecotoxicity using two aquatic species: Cnesterodon decemmaculatus and Artemia franciscana. Sedimented oil droplets were assessed using bioassays with Hyalella curvispina. Relationships between the control parameters and the composition of the mixed formulations were evaluated for all the tested dispersants.

4.11.P-We364 Chemical Mapping and Hazard Assessment of Antifouling Coating Systems on the EU Market

***Peiyu Hou**, Maria Lagerström and Erik Ytreberg, Chalmers University of Technology, Sweden*

When ships and boats are immersed in water, the attachment of fouling organisms on ship and boat hulls can happen and consequently increasing the frictional drag of vessels and fuel consumption. The most common way to prevent fouling on vessel hulls is the application of antifouling coatings, in which copper-based biocidal coatings account for the majority of the market share. However, the usage and release of copper to the marine environment has shown to be substantial, particularly in semi-enclosed environments. Several alternative systems to copper coatings are currently available on the market, which can generally be divided into four different categories: 1) non-copper biocide coatings, 2) foul-release coatings, 3) biocide-containing foul-releasing coatings and 4) hard epoxy coatings. Despite their lack of copper, these alternative coating systems may result in other kinds of emissions into the marine environment, e.g. biocides, persistent/toxic substances and microplastics (MPs). Notably, the current reporting and evaluation processes only focus on the emission of biocides when considering the introduction of a product to the European market. However, little or no information exists regarding emissions of substances such as MPs or persistent/toxic compounds, which do not fall under the legal classification of biocides. Without this knowledge, it is difficult to decide whether the alternative coating systems have a lower environmental impact, and their efficacy also needs to be further evaluated. Hence, this calls for an answer to the question: which copper-free alternative is the most sustainable choice in comparison to traditional copper coatings for ship trafficking in European waters? So far, a comprehensive evaluation of any hull coating in this regard remains absent. To address this issue, this study investigates chemicals in antifouling coating formulations that could be released into the marine environment and compares the hazards of different coating systems.

4.11.P-We365 Risk Assessment of Metals Released from In-Water Hull Cleaning in Coastal Environment: Evaluating Metal Leaching from Particulate Wastes and the Impact of Simultaneous Operations in Harbor

***Moonkoo Kim**[1], Zhi Yang Soon[2], Taekhyun Kim[1], Jee hyun Jung[1], Je Hyeok Kang[3] and Gi Beum Kim[3], (1)Korea Institute of Ocean Science & Technology (KIOST), Republic of Korea, (2)University of Maryland Center for Environmental Science, United States, (3)Gyeongsang National University, Republic of Korea*

In-water cleaning (IWC) is a widely employed method for removing biofouling from ship hulls, aiming to prevent the spread of invasive aquatic species and improve vessel efficiency by reducing hull friction and fuel consumption. With the growing application of IWC, it is critical to evaluate its environmental implications, particularly concerning the discharge of cleaning effluents that may contain hazardous substances from antifouling paints. This study investigates the chemical contamination risks associated with multiple IWCs conducted simultaneously within a harbor, focusing on both the direct release of untreated effluents and the leaching of metals from paint particles into the environment. Environmental concentrations were predicted using the Marine Antifoulant Model to Predict Environmental Concentration (MAMPEC), applying worst-case release rates of 8.07 and 11.7 µg/cm2 for dissolved copper (Cu) and zinc (Zn), respectively, based on metal concentrations measured in effluents from local IWC trials. The model also incorporated the contribution of particulate metal emissions by examining the leaching behavior of Cu and Zn from paint particles in the water column, with estimated values of 268 µg Cu and 2213 µg Zn per gram of particles. To determine the maximum demand for IWC in the port, historical vessel statistics provided by the local port authority were analyzed, categorizing vessels by size and calculating the average daily number of vessels berthing over the past decade. Risk characterization ratio (RCR) for Cu was 1.63, indicating a potential risk to marine ecosystem, while the RCR for Zn was less than one, suggesting a low risk from zinc emissions. The risk assessment highlights the need for effective recovery or treatment of effluents to mitigate environmental risk. Regulating and managing the scale of cleaning activities based on comprehensive, site-specific risk assessments is essential to protect local marine ecosystems.

4.11.P-We366 Advances in the Detection of Organic Substances in Seawater Using an Improved Vortex-Assisted Liquid-liquid Microextraction (VLLME) Approach

Valentina Di Mauro[1]*, Matthias Y. Kellermann*[1]*, David Brefeld*[1]*, Laura J. Fiegel*[1]*, Samuel Nietzer*[1]*, Mareen Moeller*[1]*, Laura Lutjens*[2]*, Sascha Pawlowski*[3]*, Mechtild Petersen-Thiery*[3] *and Peter Schupp*[1]*, (1)Environmental Biochemistry Group, Institute for Chemistry and Biology of the Marine Environment (ICBM), Carl von Ossietzky University of Oldenburg, Germany, (2)GBP/RA, BASF SE, Germany, (3) BASF SE, United States*

Marine ecosystems such as tropical coral reefs are threatened among others by organic substances introduced by agricultural runoff, wastewater discharge and/or recreational activities. These compounds include pesticides, pharmaceuticals, and personal care products (e.g., UV filters), with water solubilities ranging from mg L^{-1} to ng L^{-1} and octanol-water partitioning coefficients (Log Pow) from ~ 1 to > 5. Highly lipophilic substances may raise in combination with persistency an environmental concern, even if they are present in the environment at low concentrations. The accurate detection of such substances in both standardised laboratory experiments with corals and even environmental samples through analytical monitoring at such low concentrations (e.g., down to the pg L^{-1} to ng L^{-1} range) is needed.
Traditional methods like solid-phase extraction (SPE) can be cost-intensive and inefficient. Vortex-assisted liquid-liquid microextraction (VLLME) offers a simpler and proficient alternative with high extraction efficiency for moderate to poorly water-soluble compounds. By using a dispersing solvent, VLLME further enhances extraction across an even broader range of polarities/solubilities, making it a sensitive, efficient and fast additional approach for the analysis of organic compounds in seawater (hereafter: VDLLME).
With this study, we are extending the application of VLLME and VDLLME methods to seawater samples containing UV filters (e.g., benzophenone-3, BP-3; octyl-methoxycinnamate, OMC) and pesticides (e.g., diuron, DCMU), as the VDLLME method was mainly adapted for freshwater studies, with only limited applications for marine samples. Initial results indicate that the method presented is suitable to detecting both low substances concentrations in standardised (chronic) aquatic toxicity tests with corals and to analyse environmental concentrations.

Disclaimer/Disclosure: The authors declare that this study received funding from BASF SE (Ludwigshafen, Germany) through the grant Toxicity tests with corals and coral reef communities, grant number 5551622859. Opinions expressed in the paper are those of the authors; the funder had no role in the study design, data collection, analysis or interpretation of the study findings.

4.11.P-We367 Automated Identification of Histological Lesions in Fish Liver for Environmental Assessment

Pierre Liboureau[1]*, Enrico Riccardi*[1]*, Philip Tanabe*[2]*, Kristy Forsgren*[3]*, Daniel Schlenk*[4] *and Daniela Maria Pampanin*[1]*, (1) University of Stavanger, Norway, (2)National Centers for Coastal Ocean Science, United States, (3)California State University Fullerton, United States, (4) University of California Riverside, United States*

Stressors and pollutants often trigger both short- and long-term responses in the liver, the main site of contaminant detoxification in fish. Histopathological analysis of liver tissue is a long-standing method used to assess exposure levels in fish populations and serves as a proxy for organism health. However, dwindling numbers of trained histopathologists are unable to process ever-increasing amounts of data, at a time where such work is crucial in understanding environmental effects of climate change and rising pollution. New machine-learning (ML) tools for image identification and classification could help analyse samples more efficiently and objectively.

In this study, we selected and trained ML models to identify and quantify four common, environmentally relevant lesions in fish liver and compared results with analyses from trained pathologists. Whole-slide images were obtained from two fish species commonly used as bioindicators, Gadus morhua and Limanda limanda. For each image, a small area (up to 10%) was annotated by a histopathologist for the presence of steatosis, melano-macrophage aggregates (MMAs), leucocyte infiltration and granulocytomas. These annotated areas were used to train ML models using random forest classifiers (steatosis, MMAs) and watershed algorithms (leucocyte infiltration, granulocytoma). The models were then applied to the whole images, and the presence of each lesion was quantified. Results were compared with traditional scoring of the same slides by two independent pathologists to obtain a percentage accuracy for each lesion. Preliminary results from a limited sample (40 images) indicate strong potential for this method. All lesions displayed high comparative accuracy (≥ 80%) between traditional and ML-based results, with MMAs and granulocytomas reaching 95%, the common threshold for acceptability in medical science. Differences in accuracy between species were minimal for all lesions except leucocyte infiltration (G. morhua: 80%, L limanda: 92%). As we continue this research, increasing the size of the training set and complexity of the models, we expect to improve accuracies and correlations between digital histopathology results and biological effects, and to expand this work to include more lesions and species. This work, combined with automated slide preparation and scanning, will allow rapid turnover of samples, supporting efficient monitoring and decision-making for the protection of marine and coastal ecosystems.

Disclaimer/Disclosure: The authors thank Offshore Norge for funding, Stavanger Univeristy Hospital for slide preparation, Histowiz (NY, USA) for slide scanning.

4.11.P-We368 Challenges in Assessing Acute Toxicity of Environmental Samples in Brine Shrimp and Coral Toxicity Assays

Valentina Di Mauro[1]*, Lisa Stoetzel*[1]*, Matthias Y. Kellermann*[1]*, David Brefeld*[1]*, Laura J. Fiegel*[1]*, Samuel Nietzer*[1]*, Mareen Moeller*[1]*, Laura Lutjens*[2]*, Sascha Pawlowski*[2]*, Mechtild Petersen-Thiery*[2] *and Peter Schupp*[1]*, (1)Environmental Biochemistry Group, Institute for Chemistry and Biology of the Marine Environment (ICBM), Carl von Ossietzky University of Oldenburg, Germany, (2)BASF SE, Germany*

Coral reefs are well recognized as marine biodiversity hotspots providing various ecosystem services such as lively hoods via fisheries, tourism or coastal protection. However, they are increasingly threatened due to climate change and other anthropogenic stressors, which can enter coastal marine areas either directly (e.g. sunscreens) or through shipment, untreated wastewater and sedimentation (e.g. coatings, pesticides, heavy metals). Thus, the toxicity assessment of environmental samples towards reef building corals is needed to better understand its potential impact.

The testing of environmental samples on corals (here we use Montipora digitata) may bear some challenges, which are highlighted in this study. However, prior to the testing of the corals themselves, a range finder using brine shrimp Artemia sp. was carried out to address these challenges. Firstly, environmental samples, whether sediment, wastewater, or native water, contain complex mixtures of compounds, which, depending on the exposure regime, differ with respect to their toxicity. Secondly, seawater might interact with environmental samples, due to its composition of salts and trace elements, especially when seawater matrix compositions are changing (e.g., in salinity).

Initial results suggests that brine shrimp are equally sensitive as M. digitata when tested with individual substances. Therefore, this approach was also considered suitable for the testing of environmental samples. When using corals for the testing of environmental samples the following approaches may be adequate: use of solvents (in case of e.g. organic sediment extracts or pore water), use of double concentrated artificial sea water (in case of e.g. native water samples or sediment eluates).

This approach aims to support the advancement of consistent, coral-specific ecotoxicological testing of various environmental samples under ISO.

Disclaimer/Disclosure: The authors declare that this study received funding from BASF SE (Ludwigshafen, Germany) through the grant Toxicity tests with corals and coral reef communities, grant number 5551622859. Opinions expressed in the paper are those of the authors; the funder had no role in the study design, data collection, analysis or interpretation of the study findings.

4.11.P-We369 Comparing the Sensitivities of Oysters and Standard Aquatic Species to Pesticide Active Substances

Tara Raftery Catron[1]*,* ***Hanna Samantha Schuster***[2]*, Lennart Weltje*[3] *and Nadine S Taylor*[2]*, (1)BASF Corporation - Agricultural Solutions, United States, (2)Cambridge Environmental Assessments, United Kingdom, (3)BASF SE, Agricultural Solutions - Ecotoxicology, Germany*

To support registration of active substances for plant protection products globally, testing on three taxonomic groups of aquatic organisms (fish, daphnia, algae) covering various trophic levels is generally required. However, there are differences in ecotoxicity data requirements based on geography. For example, a marine mollusk (e.g. oyster) test is currently a data requirement for pesticide registration in the United States, but the test guideline and endpoints are not aligned with the data requirements in the European Union. These discordances may lead to questions regarding the coverage of mollusks in the aquatic risk assessment. Therefore, the goal of this project was to compare sensitivities of oysters to standard aquatic test species to better understand if this taxon is covered in the existing risk assessment framework for pesticide active substances in Europe. Oyster acute toxicity data for pesticide active substances were obtained by searching US EPA s ECOTOX Knowledgebase and regulatory documents. Acute toxicity data for fish and invertebrates were then acquired from reliable regulatory sources for each compound to match with the oyster data, and sensitivity ratios (fish or invertebrate endpoint / oyster endpoint) were calculated. Results demonstrate that oysters are similarly or less sensitive (within a factor of 3) compared to the standard fish or invertebrate test species for ~80% of substances in this dataset. For ~20% of the substances, oysters were more sensitive than the standard acute fish and invertebrate test species. However, considering the standard assessment factor of 100, these preliminary results suggest that oysters would be covered in the European aquatic risk assessment framework. A more detailed assessment of the compiled dataset is currently being conducted to look for additional trends. For instance, the substances where oysters have clearly lower endpoints than those obtained from fish or invertebrate tests will be investigated in more detail. Overall, this data analysis will help to better inform regulatory authorities on how to address potential risks to taxa currently not covered in risk assessments.

4.12 Soil Environmental Risk Assessment: Navigating Changing Regulatory Frameworks and Field-Realistic Predictions of Contaminants, Mixtures, and Stressors in Europe and Beyond

4.12.T-01 MICROSOIL – Proposal for a Refined Risk Assessment Scheme to Assess Effects on Function and Structure of Soil Microbial Communities

Karsten Schlich[1]*, Cecilia Diaz*[2]*, Kerstin Derz*[2]*, Udo Hommen*[1]*, Marie Winter*[1]*, Vivian Reiermann*[1]*, Bjoern Scholz-Starke, PhD*[2]*, Frank Zielinski*[3]*, Jens Schonfeld*[3]*, Pia Kotschik*[3]* and Silvia Piepe*[3]*, (1)Ecotoxicology, Fraunhofer Institute for Molecular Biology and Applied Ecology (IME), Germany, (2)darwin statistics, Germany, (3)German Environment Agency (UBA), Germany*

The MICROSOIL project identified meaningful endpoints for assessing effects on microorganisms exposed to chemicals in agricultural soils. Appropriate test methods were identified based on a literature search in combination with an evaluating concept. Afterwards, the sensitivity of the five identified, most suitable methods ISO 15685 (potential nitrification), MicroRespTM (substrate induced respiration), ISO 20130 (enzymatic activity), ISO 10832 (spore germination of arbuscular mycorrhiza fungi (AMF)) and the fingerprinting method ARISA was observed in three soils by using six test substances.

The nitrogen transformation test (OECD 216), was often less sensitive than other endpoints and showed deviations of up to factor 100 towards other endpoints.

Microbial respiration (MicroRespTM) and potential nitrification (ISO 15685) were less sensitive than other functional endpoints (N-transformation and enzymactic activity). Enzymatic activity (ISO 20130) presented the most sensitive endpoints. Thus, it is proposed to supplement N-Transformation by enzymatic activity (ISO 20130) in the first tier risk assessment.

The ARISA data evaluated via ordination plots revealed the same low endpoints as ISO 20130, but was less often the only approach resulting in the lowest observed effect value. ARISA has shown shifts in community structure (relative abundances) raised by chemical exposure and thus, could be useful in the lower tier. However, further research is needed to better understand the relevance of deviations from controls.

The spore gemination of AMF (ISO 10832) was more sensitive than OECD 216, but less sensitive than ISO 20130. Thus, a test with AMF is also suggested for lower tier testing. The results of the project indicate that the ISO 10832 has to be revised to allow testing of AMF in natural soils. Soil type affects the results of the tests. LUFA 2.1 was not always the soil resulting in the lowest endpoints.

In the actual risk assessment for PPP, the soil microbial community and provided ecosystem services are considered to be not at risk, if effects of the maximum predicted environmental concentration on N-transformation (OECD 216) are not larger than 25 %, latest 100 days after application. Based on the results obtained here and considering the recommendations of EFSA (2017), it is recommended to supplement the first tier risk assessment by an additional test on bacterial function (ISO 20130, enzymatic activity) and a test covering effects on AMF.

Disclaimer/Disclosure: EFSA, European Food Safety Authority (2017). Scientific Opinion addressing the state of the science on risk assessment of plant protection products for in-soil organisms. EFSA Journal 15(2).

4.12.T-02 Effects of Realistic Pesticide Mixtures on Springtails, Terrestrial Plants, and Soil Microbes – An Overview

***Paula S. Tourinho**[1], Olukayode Jegede[2], Zuzana Bílková[1] and Jakub Hofman[1], (1)RECETOX, Masaryk University, Czech Republic, (2)Soil Physics and Land Management Group, Wageningen University & Research, Netherlands*

The application of multiple pesticides over the decades has resulted in their long-term presence as complex environmental mixtures. This work aimed to assess the toxicity of realistic pesticide mixtures from 11 case study sites (CSS) to 3 different trophic levels (soil invertebrate, terrestrial plant, and soil microbes). The CSS were located in 10 European countries (Portugal (PT), Spain (SP), France (FR), Switzerland (CH), Italy (IT), Croatia (HR), Slovenia (SI), Czech Republic (CZ), The Netherlands (NL), Denmark (DK)), and Argentina (AR). The mixtures were composed of 5 pesticides (as active substances or metabolites), chosen based on their occurrence in soils from the CSS and their risk to the different groups. Three concentrations were used: median measured environmental concentration (MEC), predicted environmental concentration (PEC), and 5 times PEC (5PEC). A reproduction test was conducted with the springtail Folsomia candida, following the OECD guideline 232. Root growth inhibition test and seedling emergence and growth test were conducted based on the ISO 11269-1 and OECD 208 guidelines, respectively, with one monocotyledonous (Triticum aestivum) and one dicotyledonous species (Lactuca sativa). The microbial activity was assessed as basal and substrate induced respiration for C mineralization, and as potential ammonium oxidation and potential ammonification for N mineralization, based on the OECD guidelines 216 and 217. A significant decrease in springtail reproduction was observed in 4 CSS (ES/IT, PT, FR) at PEC. The insecticide chlorantraniliprole was present in these mixtures. Terrestrial plants were very sensitive to the exposure of pesticide mixtures in most CSS, with significant effects on seedling biomass and root growth at MEC. These results indicate that the presence of multiple pesticide residues in soil is an important route of exposure to terrestrial plants. The effects on C and N mineralization occurred at PEC and 5PEC levels in PT, SP, FR, CH, IT, CZ, and NL. Although the effects on C and N mineralization persisted up to 56 d in the most toxic CSS (PT and CZ), the microorganisms recovered after 84 d. The important outcomes from this work are: (1) effects were observed at realistic exposure concentrations (MEC and PEC); (2) one or two pesticides drove toxic effects in the mixture, for which their toxicity were known, and therefore these results were expected; and (3) in some cases, however, a mixture synergistic effect was suggested.

Disclaimer/Disclosure: This work was supported from the European Union s Horizon 2020 research and innovation program under grant agreement No 862568 (SPRINT)

4.12.T-03 Assessing the Risk of Tank Mixtures to In-Soil Organisms: From Single to Sequential Applications

***Fernanda de Santo**[1], Tiago Natal-da-Luz[1], Patricia Ferreira[2], Camila Campello[1], Julia Carina Niemeyer[3] and Jose Paulo Sousa[1], (1)University of Coimbra, Portugal, (2)CloverStrategy Lda, Portugal, (3)Federal University of Santa Catarina, Brazil*

The current ecological risk assessment (ERA) framework in the EU inadequately addresses the risks associated with the simultaneous or sequential application of tank mixtures (TMs) of plant protection products (PPPs) to in-soil organisms. This gap, highlighted in EFSA's 2017 scientific opinion, is further emphasized by the EU s Farm to Fork Strategy. This study evaluated the risks posed by single and sequential applications of four TMs, used in soybean plantations, on three non-target in-soil organisms: Eisenia andrei, Folsomia candida, and Gaeolaelaps aculeifer. The TMs consisted of 12 PPPs (15 a.s.), an adjuvant, a pH regulator, and a fertilizer, differing in components and formulation. Chronic tests followed ISO and OECD guidelines using a natural sandy-loam soil from southern Portugal. Single applications tested increasing TM concentrations, while sequential applications involved applying one TM followed by another after 14 days. Risk was assessed using the exposure-toxicity ratio (ETR), with PEC values calculated via concentration addition model (5 cm soil depth, no interception) and pesticide degradation estimated using first-order kinetics. NOEC and EC10 endpoints were used as endpoints of toxicity. Results revealed that ETR values varied across species, application scenarios, and endpoints. NOEC-based ETR indicated similar risks for F. candida and G. aculeifer in single and sequential applications. TM1 risks were PEC-driven, while TM3 and TM4 were toxicity-driven. Synergistic effects were observed for TM1+TM2, but antagonistic effects emerged in more complex mixtures (TM1+TM2+TM3 and TM1+TM2+TM3+TM4). EC10-based ETR showed increased risks in sequential applications for E. andrei and G. aculeifer, especially with TM1+TM2+TM3. TM4 reduced risks, resembling single application patterns. This study highlights the complexity of assessing real pesticide mixtures due to synergistic and antagonistic interactions and underscores the need for advanced ERA approaches. The findings emphasize the importance of species-specific responses and endpoint selection (e.g., NOEC vs. EC10) in developing comprehensive EU risk frameworks to protect soil biodiversity.

Disclaimer/Disclosure: The authors thank the Fundação para a Ciência e Tecnologia (FCT) through the PhD fellowship to F de Santo (2021.08977.BD).

4.12.T-04 Next Generation Soil Risk Assessment: Application of the FORESEE Earthworm Model for Europe

***Vanessa Roeben**, Klaus Hammel, Thomas G. Preuss, Andre Gergs and Gregor Ernst, Bayer AG, Germany*

Soil organisms, such as earthworms play a crucial role in the soil ecosystem and their potential risks due to pesticide exposure are assessed within the environmental risk assessment. Thus, the FORESEE model was developed, which is a mechanistic modular earthworm effect model, simulating earthworm behaviour to determine the effective exposure experienced in agricultural soils. The model includes the three major ecotypes of epigeic, endogeic, and anecic species and enables the extrapolation of lethal, sublethal and behavior effects from individual-level to population-level. It does that by considering the movement of the species which depends, just like the fate of chemicals, significantly on environmental parameters, such as moisture and soil conditions.

The model includes four modules: the environment, movement, toxicity, and the population module. Each module was parameterized and validated independently but interacts with each other in the overall framework. While the population level response can be predicted from behavior, sublethal and lethal effects on individual level, the FORESEE framework can be combined with field studies to prove the predictive power of the model. In the next step, the model can be used to extrapolate the results of the field study to other situations, e.g., soil and weather in different zones or different exposure situations as time or number of applications.

For this presentation, we will apply the parametrized FORESEE model that was shown to be able to predict the effects of Carbendazim on earthworms with different burrowing behaviour in a two-year field study. We will use the model to create in-silico field studies and estimate the impact of different application scenarios, such as timing, frequency, and crop stage, as well as environmental conditions from the three regulatory zones of Europe.

In conclusion, the FORESEE model can enhance our understanding of the effects of environmental fluctuations on earthworm populations and potentially support the design of earthworm field studies. The model can be used to assess the impact of different application rates, frequencies, and timings, different crops, as well as climates in other regulatory zones, on the long-term population responses of earthworms. Thereby, the model reduces uncertainty and increases the predictability of the risk assessment framework.

4.12.T-05 National Approaches to European Soil Threshold Values: A Review Towards a Degree of Harmonization

***Stijn Van Hees**[1], Xenia Trier[2], Hans Peter H. Arp[3], Dietmar Muller-Grabherr[4] and Nathalie Briels[1], (1)ARCHE Consulting, Belgium, (2)University of Copenhagen, Denmark, (3)Norwegian Geotechnical Institute (NGI), Norway, (4)Umweltbundesamt Osterreich - Team Altlasten, Austria*

Despite legislative initiatives dating back to 2006, there is currently no unified EU soil legislation in place. In the light of these earlier legislative efforts, an elaborate comparative analysis of several EU countries had been made on risk assessment frameworks and approaches to set Soil Threshold Values (STVs) for relevant pollutants. Within the context of the newly proposed Soil Monitoring and Resilience Directive (SMRD), the Horizon Europe project ARAGORN (Achieving Remediation And Governing Restoration of contaminated soils Now) initiated a new effort to compare STVs across Europe.

For all 31 countries in scope we identified relevant legal sources through national and international online public repositories. Identified legal and quasi-legal texts related to soil contamination were methodically searched and STVs extracted. Our findings have been validated as much as possible by national experts from the ARAGORN and COMMON FORUM networks.

The main finding of this comparison is that STVs are poorly harmonised across Europe. In our investigation of national legislations, we identified STVs for 26 out of the 31 countries. For five countries, no STVs were encountered in the national legislations, either because such values may not be established in these jurisdictions or because another (e.g. case-by-case) risk assessment approach is used. The median number of legislative entries (i.e. substance, sum parameter or oxidation state for metals) per country was 49, with a maximum of 130. Moreover, some countries developed different STVs for different land uses (up to more than 5 classes) while other countries apply uniform values irrespective of land use. Similarly, distinctions based on soil type (clay, loam, sand) or characteristics (pH, organic carbon content, water permeability) are applied in certain national frameworks, though these criteria are less common compared to land use. While not a primary objective of this study, STV derivation methods as well as the application of STVs within the national risk assessment frameworks showed considerable differences among countries as well.
It is concluded that the lack of harmonised STVs approach is potentially an impediment for effective soil management and remediation of contaminated sites. It is therefore suggested that the SMRD, currently under discussion, outlines a trajectory to a harmonised set of best practices for STV derivation and application in risk assessment.

4.12.P Soil Environmental Risk Assessment: Navigating Changing Regulatory Frameworks and Field-Realistic Predictions of Contaminants, Mixtures, and Stressors in Europe and Beyond

4.12.P-We370 In-field Recolonisation Rate of Soil Fauna after Precision Application with High Impact on Sub-population

Dick Belgers, Steven Droge, Marie-Claire Boerwinkel, Kas Swinkels, Nina Jansen and ***Ivo Roessink****,*
WENR, Netherlands

The incorporation of precision application of crop protection products is part of the EU Green Deal ambition to reduce pesticide use by 2030. Digital farming solutions can help farmers apply pesticides precisely where and when they are needed. Spot treatment of weeds with herbicides, for example, will in many agricultural fields strongly reduce the total amount of applied herbicide compared to conventional broadcast application. However, there is a surprisingly extensive lack of knowledge about the realistic reduction of the environmental impact of precision applications, and how these impacts can be assessed in the current risk assessment schemes. If a full field pesticide application rate exceeds the chronic no effect level for a small set of soil species (incl. a safety factor), an unacceptable risk is concluded because the recovery potential of soil organisms is hampered by their relatively slow migration rate. Population recovery can be demonstrated in higher tier assessments by full scale field studies. Spot treatment of active substances (with raised concern for impact on soil organisms), however, would leave large portions of the agricultural field untreated, and the unaffected subpopulation in these parts may actively repopulate the impacted spots via migration. In order to account for this higher tier recovery process in specific precision application GAP scenarios, the recolonisation rate potential via migration needs to be assessed. The current study assessed the recolonisation rate of earthworms under field conditions in two experimental set-ups during 3 months, in either a 6 meter container (sieved soil, free of worms, no lasting impact), or high impact hot water injection on 5 x 5 meter plots within an excessively managed meadow (>90% impact on subpopulation, no expected lasting impact). Worm traps were monitored for occurrence of adult and juvenile earthworms biweekly, including total biomass. Once 2 or more replicate traps per sampling distance contained worms, this distance was considered recolonized. The linear movement test showed recolonization over 1.5 m until 6 weeks, and full recolonization over 6 m after 8 weeks. The field plots showed worm recolonization after 4 weeks in most of the 1 m and 2 m zones, and the central 2.5 m zone after 6 weeks. This provides more detail in migration capacity than literature values of 5-15 m/y. Similar set-up could examine migration capacity for other in-soil species.

4.12.P-We371 Analytics in Soil Laboratory Studies – Technical Challenges and Implications for Soil Risk Assessment of Plant Protection Products

Gregor Ernst and ***Michael Thomas Marx****, Bayer AG, Crop Science Division, Germany,*

The Tier 1 risk assessment of plant protection products for soil organisms is conducted by comparing laboratory endpoints, e.g. no-observed effect concentration (NOEC) based on reproduction, growth, or mortality, with the predicted environmental concentrations in soil (PECsoil). So far, the ecotoxicological endpoints are expressed as nominal, initial concentrations, and are compared with the maximum, initial

PECsoil values. However, according to the Central Zone Manual analytical verification of the concentrations in the ecotoxicological laboratory tests over time are requested in case the DT90 of the compound is lower than the exposure period in the test. Time-weighted average (twa) or mean-measured endpoints shall be calculated in case the measured values do not reach 80% of the desired values. However, degradation of substances in soil is a normal phenomenon and cannot be avoided in most of the cases. Hence, a proper description of the real exposure over time in the test system can be useful for the risk assessment and may support decision making. However, many aspects remain unclear in this context and need clarity: More technical guidance is needed on the design of future laboratory studies that include analytical measurements: i.e., number of additional replicates for destructive samplings, potential introduction of soil organisms in these replicates, analytical methods. Further, the manual does not state how existing studies will be evaluated in risk assessment, e.g. EU-agreed endpoints or product endpoints. From the published manual it remains unclear how the new endpoints should be used in risk assessment. A case study is presented that shows the outcome of the Tier 1 risk assessment for two compounds with identical toxicity (nominal NOEC) with same application rate and crop stage. When considering twa NOEC and initial PECsoil values the persistent compound clearly passes the critical trigger value of 5, whereas the fast-degrading compound fails the risk assessment. However, fast degradation of compounds is per se a favorable substance property from an environmental perspective and a higher conservativeness at Tier 1 for fast degrading compounds is not justified. Hence, it is strongly recommended to consider PECtwa in the risk assessment in case the endpoints are expressed as twa or mean-measured endpoints.

4.12.P-We372 Central Zone Requirement for Analytical Measurements in Soil Organism Ecotoxicology Studies: What is the Impact?

***Christopher Taylor*[1]** *and Jennifer Duncan[2], (1)Consultant Ecotoxicologist, United Kingdom, (2)Marketing, TSG Consulting, Knaresborough, United Kingdom*

In addition to the approval and renewal of pesticide active substances at an EU level, Plant Protection Products (PPP) containing these substances must be authorised in EU Member States before they can be sold and used. These authorisations are often considered via a Zonal evaluation process, and each Zone may introduce additional or deviating approaches to standard EU-wide data requirements or risk assessment methods.

In August of 2023 the Central Zone published an update to their Working document on Risk Assessment of Plant Protection Products in the Central Zone. A significant addition to this Working Document is the requirement for ecotoxicology studies with soil organisms to include analytical verification of exposure throughout a study s duration, should the tested substance be considered as unstable defined as having a laboratory 90% degradation time (DT90) in soil of less than the duration of the ecotoxicology study. This represents a requirement not historically conducted for such studies and may therefore create a significant need to repeat studies to support future registration of PPPs in Central Zone Member States.

The aim of this presented work is to establish the impact of this new Central Zone requirement in terms of what proportion of pesticide active substances may trigger the need for analytical verification in one or more of the soil organism studies which are, in most cases, a standard regulatory data requirement for PPPs. Active substances making up the so-called AIR5 renewal list were investigated and their currently defined laboratory DT90 values were collected from publicly available EU lists of endpoints. These substance DT90 values were then compared to the in-life duration (according to current OECD test guideline methodologies) of each of the three soil organism study types included in the data requirements under Regulation (EU) No. 1107/2009.

The results of this work are presented as a proportion of the investigated active substances which would require analytical verification in at least one of the standard soil organism studies, as well as proportions which would require each individual study type to include concentration analysis. The outcome of this work illustrates the impact of this Central Zone requirement to conduct new soil organism studies (to include analytical verification of achieved exposure concentrations) to meet the requirements for future PPP registration in Central Zone Member States.

4.12.P-We373 Analytics in Soil Ecotoxicological Studies: Challenges and Approaches from a Regulatory, Biological and Analytical Perspective

Eva Aderjan[1], Giuliana Seraphim De Araujo[2], Monika Kirchherr[3] and ***Andreas Duffner*[1]***, (1)Eurofins Agroscience Services Ecotox GmbH, Germany, (2)Eurofins Agroscience Services Regulatory Spain SL, Spain, (3)Eurofins Agroscience Services EcoChem GmbH, Germany*

For the assessment of plant protection products in the European Central Zone, analytical measurements are requested for soil organism studies for some cases. Substances were the DT90 does not cover the exposure phase of the laboratory Tier 1 tests are considered as unstable and analytical dose verification must be performed at least at the start, middle and end of a study, in general.

Currently, there is only very limited guidance available and many challenges. The time points for soil samplings depend on the substance degradability and the test duration differs from organism to organism. Consequently, each product or compound needs a tailored study design to include the analytical verification. The selection of timepoints are a challenge, as the DT90 and DT50 dervied in natural soils could differ from that in OECD artificial soil. For the earthwom testing, the test organism biology might play a role for biodegradation patterns in comparison to plain soil, as earthworms likely increase the microbiological soil activity by incorporating their feed cow dung into the soil.
In a fictive scenario, we will present possible experimental designs for Folsomia candida and Eisenia fetida using destructive sampling with additional replicates for the soil analytics. The possible challenges and approaches for soil extraction and soil analysis using LC-MS/MS will be presented.
Moreover, we will compare fictive geomeans of a fast, medium and slowly degrading active on the basis of DT90 and DT50 values to evaluate the impact of using geomean endpoints dervied by analytical assessment in the Risk Assessment.

4.12.P-We374 Rethinking Soil Safety: How the 2023 Central Zone Guidance Change the Risk Assessment for Rapidly Degrading Active Substances – A Practical Case Study
***Ricardo Petersen**[1], Mariana Rato[1], Andy Chadwick[2], Ana Raquel Sales[3] and Ana Pereira[3], (1)ERM - Environmental Resource Management, Portugal, (2)ERM - Environmental Resource Management, United Kingdom, (3)Ascenza Agro, S.A., Portugal*
Soil risk assessment for plant protection products in the EU traditionally follows the Terrestrial Guidance Document (SANCO/10329/2002), using a toxicity exposure ratio (TER) that compares toxicity endpoints from laboratory studies to modeled maximum predicted soil concentrations (PECmax). Historically, toxicity endpoints have been derived from nominal concentrations.
However, the recent 2023 Working Document on Risk Assessment of Plant Protection Products in the Central Zone introduces a new methodology for active substances with DT90 values below the soil toxicity study duration for earthworms, springtails and soil mites (56, 28, or 14 days). For such active substances, analytical verification of soil concentration is required according to this methodology, in contrast with relevant test guidelines in which analytical work is not required, and when concentrations fall below 80% of nominal, study endpoints should be based on time-weighted average (TWA) or geometric mean measured concentrations. TER calculations would then rely on estimated worst-case PECmax peak values (not considering the rapid degradability in soil for a substance) and measured endpoints over a long period of time, leading to unrealistic risk assessment outcomes. Without available intermediate tier testing options, this change in the regulatory framework may lead to an increase in highly complex soil organism field studies.
This poster aims to analyse different risk assessment approaches, considering soil PECmax and PECTWA values, the sampling time points and the impact on TER calculations. For this purpose, a comparison between a set of ecotoxicological soil studies carried out according to the SANCO (2002) approach with endpoints from tests without analytical methods with the updated 2023 Central Zone approach - where analytically verified endpoints were derived - is presented here. We highlight the impacts and limitations of this new approach and discuss potential future developments for a more pragmatic soil risk assessment framework.

4.12.P-We375 MICROSOIL - Degradation Performance of Microbial Communities in Agricultural Soils after Multiple Exposure of Pesticide Active Substances
*Kerstin Derz[1], **Karsten Schlich**[1], Dimitrios Alexander Skodras[1], Udo Hommen[1], Bjoern Scholz-Starke[2], Anna Pissarello[3], Frank Zielinski[3], Jens Schonfeld[3], Pia Kotschik[3] and Silvia Pieper[3], (1)Fraunhofer Institute for Molecular Biology and Applied Ecology (IME), Germany, (2)darwin statistics, Germany, (4)German Environment Agency (UBA), Germany*
The degradability of active substances used in chemicals like plant protection products is currently estimated in laboratory tests (usually according to OECD Test Guideline 307) with standardised soils and one maximum application rate. However, agricultural used soils are exposed to multiple chemicals. Besides plant protection products, also pharmaceuticals, biocides as well as industrial chemicals enter soils through sewage sludge, fertilizers or slurry. Within one growing season, several plant protection products which may include more than one active ingredient and multiple application schemes are used, but the occurrence of multiple residues in agricultural used soils is not reflected by the current risk assessment schemes for plant protection products or other chemicals.
Within the MICROSOIL project, commissioned from the Germany Federal Environmental Agency (UBA), the correct assessment of the performance and threats of microorganisms in agricultural soils was investigated. One of four work packages analysed whether multiple applications of one substance, binary mixtures and background contamination affect the degradation time in soil. Two representative active

substances, pyraclostrobin and ethofumesate, and two representative standard soils, RefeSol 02-A and LUFA 2.1, were used for this purpose. The results show, that multiple applications of the same substance as well as the presence of another substance in soil may have both positive and negative effects on the degradation rate of the test substances used in this project. However, a negative impact on the degradation rate was shown, for instance, for ethofumesate when applied to a soil where a second substance (here: pyraclostrobin) was already present. The results indicate that further research on multiple exposure is necessary to consider more realistic use patterns and agricultural practices.

Disclaimer/Disclosure: Acknowledgement The project was funded by the Federal Ministry for the Environment, Nature Conservation, Nuclear Safety and Consumer Protection. The German Environment Agency (UBA) provided expert support (FKZ: 3720 64 411 0).

4.12.P-We376 MICROSOIL - Antimicrobial susceptibility testing to evaluate minimum inhibitory concentration values of relevant antibiotics in soil bacteria

Cecilia Diaz[1]*, Udo Hommen*[1]*, Karsten Schlich*[1]*, Frank Zielinski*[2]*, Jens Schonfeld*[2]*, Pia Kotschik*[2] *and Silvia Pieper*[2]*, (1)Fraunhofer Institute for Molecular Biology and Applied Ecology (IME), Germany, (2)Umweltbundesamt, Germany*

Within the MICROSOIL project minimum inhibitory concentrations (MIC) of for four different soil bacterial species have been determined for four antibiotics and for two other substances (heavy metal salt and detergent) were investigated in relation to soil microorganisms. While the EUCAST database provides MIC data for clinical bacteria, similar information for soil bacteria is lacking. By evaluating whether soil bacteria are more sensitive to antibiotics than clinical strains, this study provides essential data for environmental risk assessments.

Strains were chosen based on their ecological relevance in soil, maximizing diversity among the selected organisms, and the availability of genomic data. Four strains were selected, with known genomic information: Arthrobacter sp., Lactobacillus plantarum, Pseudomonas gessardii, and Acidovorax facilis. MICs were determined using the broth microdilution method following EUCAST protocols. For each substance (colistin sulfate, neomycin sulfate, chlortetracycline hydrochloride, tiamulin hydrogen fumarate, copper sulfate, and TWEEN 20.), eight concentrations were tested with three controls included: inoculation control, substance control, and media control. The variability in MICs between strains spanned up to two orders of magnitude; Acidovorax facilis showed the lowest MICs for two of the antibiotics tested, while Arthrobacter sp. was never the most sensitive strain. The lowest MIC recorded was 0.06 mg/L for chlortetracycline hydrochloride. In comparison with MICs derived for clinical strains (available from EUCAST database) no systematic different sensitivity of the soil strains tested here was found. For the four antibiotics tested, a predicted environmental concentration for soil based on the intended use of this substance was only available for Tiamulin. The risk quotient (RQ) based on the minimum MIC and without using an assessment factor was >100 and larger than the RQ based on the standard ecotoxicological tests, suggest that MIC could be a relevant endpoint in the risk assessment of antibiotics.

Disclaimer/Disclosure: Acknowledgement The project was funded by the Federal Ministry for the Environment, Nature Conservation, Nuclear Safety and Consumer Protection. The German Environment Agency (UBA) provided expert support (FKZ: 3720 64 411 0).

4.12.P-We377 How to Include Effects on Soil Functioning in Soil ERA? An Ecological Perspective

Ingrid Rijk*, Orebro University, Sweden*

Soil contamination of any kind (metals, organics, plastics, nutrients) may disrupt soil microorganisms with important roles in carbon (C) and nitrogen (N) cycling. Effects of contaminants on soils has traditionally been most focused on its visible inhabitants, mainly plants and wildlife, and biased towards economically important crops. The effect of contaminants on soil microbial communities and their activity has been largely neglected, or overly simplified. Often, effects on soil microorganisms are tested with short-term tests under laboratory conditions. However, how the functioning of microorganisms are affected in field soils is unclear, which may lead to a mismatch between soil ERA and field effects.

Microbial parameters with a direct link to soil C and N cycling such as microbial respiration, biomass, N process rates and enzyme activities are often proposed to assess changes in soil quality and rely on a large availability of well-established methods. Microorganisms are known to response rapidly to environmental changes (hours days) as they have intimate relationships with their surroundings due to their relatively high surface-to-volume ratios. However, the variable intensity and direction of response make their implementation and interpretation in soil risk assessment challenging. Instead, a combined approach that includes plant and soil parameters provides a more integrated view on potential ecosystem changes.

To demonstrate this approach, various studies were undertaken to assess the effects on C and N cycling in contaminated soils under realistic (field) conditions. A variety of microbial responses, such as in situ microbial soil respiration (BR, SIR), biomass, and N cycling microbial guilds were measured in two historically contaminated sites and two outdoor field trials. The microbial responses were linked to slower responding plant and soil variables and stable isotopic content ?13C and ?15N.
The ecosystem effects in the two field soils, and soil specificity of microbial responses in the N cycle, support the view that soil contamination can have long-lasting effects. However, different intensities and the lack of connection with bioavailable fractions of metals, stress the need for site-specific approaches.

4.12.P-We378 ERAMYC: Results of a Ring Test for Standardization of Arbuscular Mycorrhizal Fungi Pre-Symbiotic and Symbiotic Phases Tests for Environmental Risk Assessment Schemes
***Patrícia Ferreira**[1], Tiago Natal-da-Luz[1], Luis CI Oliveira Filho[2], Tanel Vahter[3], Pia Kotschik[4], Silvia Pieper[4], Susanne Walter-Rohde[4], Sonia Purin da Cruz[5], Susana Rodriguez-Echeverria[6], Mari Moora[3], Jose Paulo Sousa[6] and Osmar Klauberg-Filho[7], (1)CloverStrategy Lda, Portugal, (2)Santa Catarina State University & Federal University of Santa Catarina, Brazil, (3)University of Tartu, Estonia, (4)German Environment Agency (UBA), Germany, (5)Federal University of Santa Catarina, Brazil, (6)Centre for Functional Ecology, Associated Laboratory TERRA, DCV, University of Coimbra, Portugal, (7)Santa Catarina State University, Brazil*
The presence of arbuscular mycorrhizal fungi (AMF) in terrestrial ecosystems is essential due to the benefits these organisms provide to their host plant and to several key ecosystem services.
Ecological relevance and sensitivity of AMF to contaminants led the European Food Safety Authority (EFSA) to identify AMF as a potential group of non-target in-soil organisms to be included in risk assessment of plant protection products (PPPs). To date, there are no standardized OECD Test Guidelines for the performance of tests with AMF, but two standardized methods are available, the ISO/TS 10832:2009 for pre-symbiotic testing and the AFNOR, FD X 31-205-2, for symbiotic testing.
The ERAMYC project aims to fill some of the gaps identified by EFSA by improving the existing ISO document for pre-symbiotic testing and by developing and standardizing a laboratory method for symbiotic testing. A ring test was conducted to assess the feasibility and reproducibility of these methodologies with the final objective of developing an OECD international standard for AMF pre-symbiotic and symbiotic testing.
A methodology to assess the effects of the test substances on the AMF-plant symbiosis was developed and the method described in the ISO protocol for pre-symbiotic testing was adapted and refined with new methodological steps and different test conditions. The ring test for both methods was carried out using the AMF Rhizophagus irregularis, the host plant Allium ampeloprasum, OECD 2.5% soil and the test substances azoxystrobin and fluazinam.
Results of the symbiotic phase tests showed some variability and so far it was not possible to find a suitable reference substance. Toxicity observed in the pre-symbiotic phase tests tended to be lower than that observed in the symbiotic phase tests.
The variability of data obtained, especially in the AMF symbiotic phase testing, and the difficulty in finding a suitable reference substance may hamper the standardization of the method. On the other hand, the toxic effects of the test substances to AMF observed in the ring test tended to be in the same order of magnitude or higher than the toxicity data from literature for non-target standard in-soil species, which suggests that the AMF communities may, in some cases, be insufficiently covered by the standard species currently considered in the ERA of PPPs in European Union. However, further tests are needed with a larger set of test substances to substantiate this assumption.

Disclaimer/Disclosure: The authors thank the German Federal Ministry for Environment, Nature Conservation, Nuclear Safety and Consumer Protection for funding this project (FKZ 3720 64 407 0), the German Federal Environment Agency (UBA) for scientific support, and CNPq for granting the scholarship nº 171737/2023-7.

4.12.P-We379 Independent Yet Complex: Decoding Soil Moisture and Pesticide Interactions in Toxicity Tests with Folsomia candida (Collembola)
***Liyan Xie**[1], Saul Fernandes[2], Stine Slotsbo[3], Martijs J Jonker[4], Cornelis A.M. van Gestel[2] and Martin Holmstrup[3], (1)Aarhus University, Denmark, (2)Vrije Universiteit Amsterdam, Netherlands, (3) Aarhus University, Denmark, (4)University of Amsterdam, Netherlands*
Soil humidity conditions are crucial factors in the life of soil invertebrates, but it can also significantly influence the toxicity of pesticides which may be taken up through the soil pore water. Yet its role remains underexplored in ecotoxicology. This study therefore evaluated the impact of soil moisture content on the toxicity of the insecticide teflubenzuron to the collembolan Folsomia candida using OECD 232

reproduction tests. We tested six concentrations of teflubenzuron plus two controls, combined with eight levels of soil moisture corresponding with soil water potentials between 1.8 and 721 -kPa. This broad range covers optimal, extreme drought, and wet conditions, providing a comprehensive overview of soil moisture interaction with pesticides. After 28 days of exposure, we characterized the interaction between soil moisture content and teflubenzuron effects on adult survival, final body mass of adults and reproduction, using the MIXTOX tool. The concentration addition model showed dose-ratio dependent antagonism for reproduction, but no deviations from additivity for body mass. The independent addition model best explained the combined effects of soil moisture and teflubenzuron on springtail reproduction and biomass. This indicates that neither synergistic or antagonistic interactions, nor dose-level or dose-ratio dependence deviations were found. However, survival patterns were more complex with higher survival rates in dry soils at high teflubenzuron concentrations compared to moist soils. Further analysis confirmed that teflubenzuron accumulation was greater in moist soils at high exposure levels, explaining the higher mortality at high soil moisture. This study thoroughly investigates how soil moisture content interacts with pesticides and provides added value to the standard toxicity test.

4.12.P-We380 Effects of Metal-Based fungicides on the Growth, Reproduction and Avoidance Behaviour of Eisenia Andrei Under Varying Temperatures and Moistures

Hussain Kaka*[1]*, Mark Maboeta*[1] *and Prosper Ashibudike Opute*[2]*, (1)North-West University, South Africa, (2)University of Benin, Nigeria

This research investigated the ecotoxicological effects of metal-based fungicides in the context of contemporary global climate change scenarios, specifically at temperatures of 20°C and 25°C, and moisture levels of 30% and 50%. The study focused on both single and binary mixtures of copper oxychloride (CuOx) at concentrations of 200, 500, and 1000 mg/kg, alongside mancozeb (MnZn) at 44, 850, and 1250 mg/kg. Key endpoints evaluated included mortality rates, biomass alterations, avoidance behaviour, and reproductive success, following standardized protocols established by ISO and OECD. The assessments of biomass and mortality were conducted over a 28-day period, succeeded by a 28-day reproduction assessment and a two-day avoidance behaviour evaluation. Across all temperature and moisture combinations, mortality rates in the exposed groups surpassed 10% solely in the CuOx1000 and CuOx1000+MnZn1250 mg/kg groups. Notably, at 20 °C and 30% moisture, the mortality rate exceeded 10% only in the CuOx500+MnZn850 mg/kg treatment. The relative growth rates in the CuOx and MnZn treatment groups exhibited a decline with increasing concentrations. In the CuOx, MnZn, and their binary mixtures under conditions of 20 °C at 30% moisture and 25 °C at 50%, avoidance behaviour remained above 80% throughout the exposure period, with exceptions noted for CuOx200 mg/kg, MnZn44 mg/kg, and CuOx200+MnZn44 mg/kg. The reproductive output of earthworms in all treatment groups was found to be concentration-dependent and influenced by varying temperature and soil moisture conditions. Notably, no juveniles or cocoons were produced in the CuOx1000 mg/kg treatment at 25°C and 30% moisture, suggesting that copper oxychloride may exhibit greater toxicity than mancozeb, particularly under drought conditions. This study concluded that variations in temperature and soil moisture significantly affect the ecotoxicity of CuOx and MnZn, indicating that climate change is likely to have profound implications for the ecological roles of metals in earthworm populations.

Disclaimer/Disclosure: Open access funding provided by North-West University. The authors thank the Unit for Environmental Sciences and Management at the North-West University in South Africa for their funding and research support.

4.12.P-We381 The Effect of Environmental Conditions on Heavy Metal Toxicity to Earthworm Eisenia fetida in Sewage Sludge-Amended Soil

Inesa Kniuipyte*[1]*, Diana Miškelytė*[2]*, Marius Praspaliauskas*[1] *and Jurate Zaltauskaite*[2]*, (1)Laboratory of Heat Equipment Research and Testing, Lithuanian Energy Institute, Lithuania, (2)Department of Environmental Sciences, Vytautas Magnus University, Lithuania

The amount of sewage sludge (SS) is continuously increasing, posing challenges for its utilization. SS is primarily applied in agriculture and landfilling, but its benefits for soil due to high organic matter and essential nutrients are countered by its pollutant content, including heavy metals (HM), organic pollutants and other toxic substances. Current SS application regulations only focus on HM and nutrient levels, overlooking risks to soil biota and ecosystem functions. Climate change alters the dynamics of pollutants, affecting their dispersion, bioavailability, and impact on soil organisms. Consequently, SS fertilization rates must be adjusted with ongoing climate change. Earthworms are widely recognized as model organisms for assessing soil toxicity due to their ecological significance, sensitivity to contaminants and reliability as indicators of soil health. Adverse impacts of SS on earthworms can impair ecosystem functions, leading to diminished soil fertility and biodiversity. Understanding how increasing temperature

and altered soil moisture will change SS impact on soil dwelling biota is critical for SS management and reuse in agriculture and forestry.
This study aimed to analyze the single and combined effects of air temperature (21 and 25ºC) and soil water content (SWC optimal, reduced, and elevated) to earthworm Eisenia fetida in SS amended soil (0-50 t/ha). Growth and mortality were measured weekly, and oxidative stress was assessed at the end of the experiment using biochemical indicators such as superoxide dismutase (SOD), catalase (CAT), and malondialdehyde (MDA). The results showed that E. fetida is tolerant to low HM mixture pollution in SS-amended soil under changing climate conditions. Lowest SS doses (12.5 and 25 t/ha) promoted growth at optimal SWC, while the highest SS dose (50 t/ha) caused the biggest mortality in all analyzed SWC levels. The earthworm s antioxidant system, crucial for metal detoxification, played a key role in mitigating toxic effects. Elevated temperature (25ºC) intensified the harmful impact of HM across all SWC levels. Controlling environmental conditions (temperature, substrate compatibility, etc.) and pollutant levels is crucial to soil organisms. This study provides insights into the interactions between climate factors, pollutant toxicity, and soil organisms, offering valuable implications for future bioremediation efforts and the use of SS as fertilizer.

4.12.P-We382 Transforming Planetary Regolith into Viable Substrates: An Ecotoxicological Approach

*Vickey-Luanne Harris, Hindrik Bouwman and **Mark Maboeta**, North-West University, South Africa*
Space agencies have been planning long-term missions to the Moon and Mars for many years. Currently, bioregenerative life support systems are used to provide food in space. Utilizing in situ resources and limiting terrestrial input into these systems would be ideal as it would be cost-effective. In situ resources, however, contain potentially harmful elements, such as heavy metals and fine particle matter. Overall, there is limited research on the toxicological profile of planetary regolith. Therefore, this study aims to assess the toxicity of the regolith using earthworms as bioindicators and turning the regolith simulants into soil that can support the growth of radishes. Lunar Highlands (LHS-1) and Martian Global (MGS-1) simulated regoliths were used alongside a control as earth soil. Growth, reproduction and avoidance assays with Eisenia andrei were carried out using the simulants at 100%, 80%, 60%, 40% and 20%. To transform the regolith, organic compost and Eisenia andrei were added to the soil to support the plant growth. The final concentrations of Earth, Lunar and Martian soils in the experimental setup were 70%, 70% and 50%, respectively. Raphanus sativus (radish) was grown in the soil mixtures over three cycles. On day 28, the plants were harvested and measured before being oven-dried. They were weighed, and the metal content in the leaves, radishes, soil and worms was determined using ICP-MS. Regarding the earthworm exposures, 100% LHS-1 and 100% and 80% MGS-1 resulted in total mortality. However, LHS-1 at 20%, 40%, 60%, and 80%, and MGS-1 at 20% showed minimal adverse effects in growth and reproduction assays. The earthworms did, though, avoid both regoliths at 60% and 80%. Finally, MGS-1 at 40% and 60% resulted in impaired growth, a lack of juveniles, and 60% led to eventual mortality. In the potting experiment, the radishes were successfully grown in the Lunar soil with biomass inhibition as low as 32%, and in the Martian soil, inhibition was as high as 80%. Whilst there were no significant differences across the three growth cycles, this study hypothesizes that there is heavy metal transfer to the plants and earthworms that could make them harmful for consumption. The findings of this research could contribute valuable insights into sustainable agricultural practices for future space exploration and colonization.

4.12.P-We383 Approaches to Better Monitor the Effects of PPP on Soil Mesofauna: A Regulatory Perspective

*Franck Brulle[1], **Julie Ravat**[2], Sophie Joimel[3], Pierre-Francois Chaton[1], Emilie Farama[1] and Vanessa Mazerolles[1], (1)ANSES French Agency for Food, Environmental and Occupational Health & Safety, France, (2)ANSES, maison alfort, France, (3)University Paris-Saclay, INRAE, AgroParisTech, UMR ECOSYS, France*
For the authorization of plant protection products (PPP) in the context of the Regulation (EC) No 1107/2009, an a priori regulatory risk assessment includes a risk characterization for the soil compartment and soil non-target organisms such as earthworms or collembola and acari. For these organisms, data requirements set by Reg. (EU) No 283 and 284/2013 are chronic laboratory studies. Following the European guidance for terrestrial ecotoxicology (EC, 2002) tiered approach, unacceptable adverse effects identified with these laboratory data would likely trigger the need for more complex higher-tier studies. Classically, field study are performed and used to refine the risk assessment, accordingly. While a guideline is available to conduct earthworm field studies, no such guideline is yet available for soil mesofauna. This lack of clear methodology introduces numerous shortcomings related to study design, sampling methods and species identification as mesofauna field studies are mainly performed following recommendations set for other soil-dwelling organisms (i.e. earthworms) but not exclusively (i.e. non-

target arthropods). To date, field studies focused almost exclusively on overall abundance variation related to PPP application despite the fact that soil mesofauna is known to be involved in primordial ecosystemic services in soil (i.e. soil aggregation, organic matter degradation, etc.). To overcome these issues, it appears interesting to develop/test existing approaches already available for soil quality evaluation. For instance, despite the fact that abundance and identification to the species level are commonly performed in these field studies, nothing is proposed to calculate diversity indices to obtain information about community dynamics after application of PPPs. In addition, trait-based approaches recently developed to study soil invertebrates responses to environmental changes may be regarded as promising a tool. More precisely, functional traits analysis have already showed good results in the context of contaminants exposition (Metallic trace elements, PPP, etc.).
The aim of this poster is to identify and discuss existing approaches that would be likely useful for mesofauna field studies in the frame of Reg. (EC) N°1107/2009. Pro and cons would be listed and relevance and reliability of each approach will be discussed.

4.12.P-We384 Normal Operating Range of Earthworms in European Agricultural Fields
*Amund N. Lovik[1], Melanie Bottoms[2], Tania Alvarez[1], Roman Ashauer[1], **Neil Sherborne**[2] and Nika Galic[1], (1)Syngenta Crop Protection, Switzerland, (2)Syngenta Crop Protection, United Kingdom*
Normal operating range (NOR) is used as a measure of natural variability of ecological quantities, but its exact definition and method of calculation depends on the intended use. It has been proposed to use NOR to define an ecologically relevant level of effects of plant protection products on populations of non-target organisms, both when effects are quantified with field studies as well as with population models. In this contribution, we demonstrate how a NOR for earthworms can be calculated based on systematic spatial variability of abundance in untreated control data from field effect studies, using a generalized linear random effects model. We quantify NORs for three species of earthworms common in European agricultural fields, Lumbricus terrestris, Aporrectodea caliginosa and Aporrectodea rosea, using data from 27 field studies conducted in Denmark, Germany, Spain and UK between 1997 and 2021. At the scale of a field study, we determined relative spatial 90% NORs of 87% to 115% for L. terrestris, 80% to 125% for A. caliginosa, and 64% to 157% for A. rosea. While there were indications of seasonal differences in abundance, the relative spatial variability was well described by a single range across all seasons. Remaining variability fitted well to the Poisson distribution for L. terrestris, while data for A. caliginosa and A. rosea displayed overdispersion and were better described using a negative binomial distribution.

4.12.P-We385 Recovery of Earthworm Populations in Field Test Plots Through Migration?
***Silvio Knaebe**[1], Tobias Vollmer[2], Anja Hamberger[2] and Olaf Klein[2], (1)Eurofins Agroscience Services US, Germany, (2)Eurofins Ecotox, Germany*
Earthworm field tests are used as highest tier in the risk assessment for in-soil organisms. Differences in earthworm populations (population size and composition) of test item treated and untreated field plots are assessed at different timings after application of the test item, thus covering short-term effects (1 month after application) as well as medium to long-term effects (6 months, 12 months after application) including recovery.
If full recovery is observed after a one-year trial period, the risk is estimated to be low (De Jong et al., 2006; EFSA, 2017). The test (ISO guideline 11268-3, ISO 2014) is typically carried out on plots with a minimum size of 10x10 m that are separated from each other by untreated strips.
It is known that earthworms are capable of active dispersal (e.g. EFSA 2017, Grigoropoulou & Butt 2010, Emmerling & Strunk 2012) and it could thus be postulated that migration could lead to an overestimation of the recovery potential of earthworm populations when studying small experimental plots especially when the distance to potential source areas for migration (untreated areas) in relation to the potential dispersal rate is much smaller than in real world field situation with much larger distances to untreated areas (field margins etc.).
A series of field experiments was set up in order: (a) to estimate the contribution of migration from untreated areas to the recovery of strongly damaged earthworm populations and (b) to evaluate whether migration could be reduced by either setting up mechanical barriers at the plot borders or by separating the plots from untreated areas by strips of intensively cultivated soil. Additionally, data from >50 earthworm field studies following ISO 11268-3 with pairs of toxic standard and water-treated plots were evaluated. Results of these field experiments and data assessments will be presented and discussed.

4.12.P-We386 Comparison of Soil Ecotoxicity Results Using the TRIAD Method and USETox Ecotoxicity Assessment for Abandoned Mine Sites
***Seung-Woo Jeong**[1], Songhee Kim[1], Rabin K.C[1], Dajung Kim[1] and Youn-Joo An[2], (1)Kunsan National University, Republic of Korea, (2)Konkuk University, Republic of Korea*

To assess the ecological risk of contaminated soils, the ISO has recently proposed the TRIAD method. This approach evaluates Integrated Risk (IR) of contaminated sites based on three Lines of Evidence (LOE): chemical assessment, ecotoxicological assessment, and ecological assessment. In contrast, USETox is an ecotoxicity impact assessment method used in Life Cycle Assessment (LCA) to evaluate the potential ecotoxic effects of pollutants released into specific regions. The fundamental difference between these two methods lies in their focus: while the TRIAD method provides a practical ecological risk assessment of already contaminated sites, the USETox method predicts potential ecotoxicity caused by pollutant emissions. This study compares the practical ecological risk assessment results from the TRIAD method with the potential ecotoxicity impacts calculated using USETox for two abandoned mine sites.
The TRIAD method indicated a "Moderate Risk" or higher for both sites, with minimal differences in ecological risks between them. However, the absolute ecotoxicity values derived from the USETox method were significantly higher. Despite these differences, the ranking of ecological severity between the two sites was consistent across both methods. The notable discrepancies in ecological risk outcomes between the two methods are attributed to differences in exposure scenarios and spatial coverage. The TRIAD method calculates risks based on direct exposure to contaminated soil within the site, while USETox employs predicted values derived from Species Sensitivity Distributions (SSD) and assumes uniform distribution of contaminants across the entire site. This study suggests that USETox could be effectively utilized for prioritizing ecological risk assessments and remediation efforts for contaminated sites. Further research on USETox adaptations to improve reliability for site-specific soil ecotoxicity evaluations is also recommended.

4.12.P-We387 Evaluation of an AI-based Software System for Counting and Body Size Measurement of the Springtail Folsomia candida in OECD 232 Reproduction Tests

*Eiko Wagenhoff[1], Benjamin Hoferlin[2], Markus Hoferlin[2] and **Andreas Duffner**[1], (1)Eurofins Agroscience Services Ecotox GmbH, Germany, (2)Visionanalytics, Germany*

The springtail reproduction test (OECD 232, 2016) with Folsomia candida is an essential part of the test battery for environmental risk assessment of plant protection products in the soil compartment.
Even though the reproductive output for a valid test requires 100 juveniles per control replicate at the end of the 28-day test period only, the actual number of juveniles is usually much higher and can reach values well over 1000. After extraction from the test soil with dyed black water, the white coloured adult and juvenile springtails are floating on the water surface and can be counted either directly under the binocular or on the computer using photographs taken from the water surface. In either way, manual counting is very time consuming, laborious, and prone to error.
To facilitate, accelerate, and standardise the counting process, the software FOLSOMIACOUNTER was developed to enable automated juvenile counting from photographs of the water surface after extraction. Additionally, an AI-based functionality allows estimating the body size of the counted adult and juvenile springtails. This supports observers to look for sublethal effects other than reproduction. Over the past years, the AI of the software has been continuously trained and improved with photographs of different quality.
We compare the results on counting juveniles on photographs from the yearly toxic reference item studies from 2016 until 2024 on both methods: manual and software-based assessment. These photographs were chosen because they are not part of the continuous training process of the software. The results regarding the following dimensions are discussed on the poster: (a) the achieved time saving, (b) the counting accuracy, (c) the impact on the main ecotoxicological endpoint EC50, and (d) the potential of body size measurement as an additional sublethal parameter in this type of test.

4.12.P-We388 The FORESEE Earthworm Model – from Conceptualisation to Completion

***Natalie Albrecht**[1], Kim Rakel[1], Josef Koch[1], Andre Gergs[2], Gregor Ernst[2] and Vanessa Roeben[2], (1)gaiac Research Institute, Germany, (2)Bayer AG, Germany*

Soil risk assessment of plant protection products is based on a two-tiered approach, where if the Tier 1 is not passed, field studies can be conducted to demonstrate that soil organisms are not at long-term risk. Field studies are time- and labour-intensive, and can only represent a snapshot of conditions, i.e., the tested climatic conditions, soil properties, and species composition. Mechanistic population models are a promising tool to extrapolate from these studies to different populations and environmental conditions. For the past 6 years, we worked on an earthworm population model, namely the FORESEE, to establish such a tool. The model was setup through collaborative efforts of experts from many disciplines, reaching

from earthworm ecologists, fate and risk assessment experts to modellers, to ensure a scientifically sound model with the help of the combined expertise and broad stakeholder engagement. The model integrates state-of-the-art concepts, such as dynamic energy budget and toxicokinetic-toxicodynamic theory, in a modular approach to provide a generic model, which supports a quick and easy change of species, ecological type and environmental conditions. In this modular approach the different model assumptions are readily interchangeable, which makes it a flexible tool for intermediate and higher tier risk assessment applications.
To encourage and inspire the set-up of more such models and enhance acceptability of these for soil risk assessment, we present the time course and important milestones of our project from first ideas collected in a workshop in 2018 to the final model validated with a field study to be published in 2025.

4.12.P-We389 Assessment of Surface Water and Soil Quality in the Vicinity of Cattle Farms Using an Ecotoxicological Approach
*Gintare Sidlauskaite[1], Oleksandra Nikolaieva[2], Diana Miškelytė[2], Austra Diksaityte[2], Giedre Kaciene[2], Gintare Sujotoviene[2], Irena Januskaitiene[2], Renata Dagiliute[2] and **Jurate Zaltauskaite**[1], (1)Vytautas Magnus University, Lithuanian Research Centre for Agriculture and Forestry, Lithuania, (2)Vytautas Magnus University, Lithuania*
Currently, more than 5.7 million livestock farms are counted in the EU. Annual manure production in the EU reaches around 1.4 billion tonnes of which 75% derives from cattle. Manures are commonly applied to agricultural land for fertilization and represents a major route for the spread of nutrients and veterinary antibiotics in the environment. The main purpose of this study was to analyse soil and water quality in the vicinity of cattle farms of different size (500-1000 and >1000 livestock units (LU) through chemical and ecotoxicological parameters. The toxicity of surface water and soil leachates were assessed with Lemna minor and Daphnia magna bioassays. Results indicated that environmental surface water and soil samples exhibited inhibitory effect on the growth of Lemna minor and D. magna reproduction. Impaired L. minor growth and D. magna reproduction could be linked to antibiotic concentration in the samples.

4.12.P-We390 Promoting Sustainable Agriculture with Entomo-Fertilisers from Black Soldier Fly: Nutrient Leaching and Ecotoxicity Assessment of Leachates
***Ines Bento Cruz**[1], Amid Mostafaie[1], Jose Nereu Pinto[1], Diogo Filipe Nunes Cardoso[1], Susana Loureiro[1], Ana Rita R. Silva[1], Ana Eduardo Rodrigues[1] and Iva Guidini Lopes[2], (1)Centre for Environmental and Marine Studies (CESAM) & University of Aveiro, Portugal, (2) Swedish University of Agricultural Sciences, Sweden*
The overuse of chemical fertilizers in agriculture has significantly degraded soil quality, reducing biodiversity and harming ecosystems health. Nitrate leaching is a particular concern and occurs when rain and irrigation occur through soil layers, eventually reaching and contaminating groundwater reservoirs. Organic fertilizers derived from insect waste bioconversion - entomofertilizers - have been explored to address this environmental issue as sustainable alternatives that may partially replace conventional fertilizers. Besides their slow nutrient release into the soil, entomofertilizers are generated through a circular production process that reuses waste organic materials, such as olive pomace, which would otherwise have toxic environmental effects. This study aims to evaluate the leaching behavior and environmental impacts of different entomofertilizers produced from Black soldier fly (BSF) bioconversion (cereal and olive pomace as a substrate) in the soil, compared to mineral synthetic fertilizer. The leaching experiment was performed similar to OECD guideline 312, with some adaptations. Fertilizers were incorporated into standard Lufa 2.2. soil at a depth of 10 cm at the top of the column. The soil columns water-holding capacity was adjusted to 60%. Six treatments with five replicates were tested: control (no amendment); soil amended with a synthetic fertilizer; BSF cereal frass, and BSF olive pomace frass. Both entomofertilizers were tested in powder and pellet form according to the commercial formulations. A simulated precipitation rate of 221.9 mm was applied over 28 days, representing a winter month in Aveiro, Portugal. Leachates were collected, quantified and frozen after every second precipitation day. At the end of the experiment, leachates were subsequently filtered and analyzed for nutrient characterization and acute ecotoxicological assays using Raphidocelis subcapitata, Lemna minor and Daphnia magna were performed. Nutrient content in both the top and bottom soil layers was also determined. Nutrient leaching was reduced under frass treatments compared to synthetic fertilizer, with lower nutrient loss to leachates as well. We also observed no ecotoxicological effects in the tested organisms exposed to the leachates. This study provides valuable insights into BSF-based fertilizers direct and indirect environmental impacts, supporting a shift toward more sustainable agriculture practices.

4.12.P-We391 Pesticide Residues in African Agricultural Soils

Vera Silva*, Xiaomei Yang, Rima Osman and Coen J. Ritsema, Soil Physics and Land Management Group, Wageningen University & Research, Netherlands*

According to Tang et al. (2021), 64% of global agricultural land is at risk of pesticide pollution by more than one active ingredient, and 31% is at high risk. Among the high-risk areas, about 34% are in high-biodiversity regions, 5% in water-scarce areas and 19% in low- and lower-middle-income nations. Validation of these figures by field measurements is particularly challenging. This is mostly because of the limited post-approval monitoring of pesticides, and lack of soil-specific protection instruments, in Africa, and in general, but also because of the high costs and analytical challenges of analyses of such a diverse group of contaminants.
There are a few studies on pesticide contamination on African soils, but of rather limited coverage (geographical area, pesticide residues), and high variability on field and analytical details, hampering an overview of contamination, and ultimately of soil health. Therefore, to provide a first assessment of pesticide contamination, over 300 of the Soils4Africa soil samples were tested for a wide spectrum of pesticide residues (n=165). The h2020 Soils4Africa project aims to provide an open-access soil information system populated with data on the basic soil properties of ~ 20,000 topsoil samples. Pesticide samples were collected arable systems, are assumed to cover a mixture of real-field conditions (crops, farming systems, and pesticide use regimes). The target list was put together based on residues found in literature, application records, and pre-screening of 10% of samples. Pesticide analyses were done via LC-MS/MS-based and GC-HRMS-based methods, according to the JRC LUCAS 2018, and EU-SPRINT 2021 SOPs. The analytical work is being finalised and will allow to make inferences on overall, country, crop, and pesticide-level; with the main indicators being: number contaminated/ clean samples; Residues found/not found; mixtures in soil, Number residues/sample, level residues/sample, Frequency detection of different pesticide residues. Inferences on levels/thresholds/hazard of pesticides will be also performed. Our results can ultimately help define soil and pesticide monitoring priorities/watch list, assess pesticide pressure on ecosystems and human health, and Support decision-making concerning pesticide use/approvals/transition.

Disclaimer/Disclosure: Soils4Africa Project has received funding from the European Union Horizon 2020 Research and Innovation Programme under Grant Agreement 869200

4.12.P-We392 Effects of Realistic Pesticides Mixtures on the Springtail Folsomia candida

Paula S. Tourinho*, Zuzana Bílková and Jakub Hofman, RECETOX, Masaryk University, Czech Republic*

The application of multiple pesticides over the decades has resulted in their long-term presence as complex environmental mixtures in European agricultural soils. Recent publications have shown that European soils present high levels of some pesticides, which may represent a risk to terrestrial non-target species. Therefore, assessing the risks of pesticide mixtures is extremely important. This work aimed to assess the toxicity of 11 pesticide mixtures to springtails. For each mixture, 5 pesticides were selected based on their occurrence in soils from 11 case study sites (PT-Portugal, SP-Spain, FR-France, CH-Switzerland, IT-Italy, HR-Croatia, SI-Slovenia, CZ-Czech Republic, NL-The Netherlands, DK-Denmark, and AR-Argentina) and their risk quotient. The risk quotient was calculated using available data on their toxicity to soil invertebrates and predicted environmental concentrations (PEC) retrieved from EFSA reports. Three concentrations were chosen: the median measured environmental concentration in soils (MEC), the predicted environmental concentration (PEC), and 5 times PEC values (5PEC) of the selected pesticides. Reproduction tests with the springtail Folsomia candida were conducted in agricultural soil, following the standard guidelines. Data was analyzed by One-way ANOVA, followed by Dunnett s post hoc test. Effects on springtail survival, size, and/or reproduction were observed in 5 mixtures. In PT and FR mixtures, effects on survival and reproduction were observed at PEC and 5PEC. In SP and IT, the effects on reproduction were also observed at PEC, and survival at 5PEC. In HR, effects on survival were observed at 5PEC. The toxicity observed in the FR and PT mixtures was higher than expected when considering the NOEC values of the single pesticides reported by EFSA. For instance, at PEC level, the reproduction was decreased in 90-95% of the control. The mixture composition of most toxic CSS (ES/IT, FR, PT) had the insecticide chlorantraniliprole, which is highly toxic to springtails, and the fungicides boscalid and difenoconazole. The results suggest a possible mixture effect due to the combination of chlorantraniliprole and azole fungicides. This work provides new information on the effects of realistic pesticide mixtures, which aims to contribute to a comprehensive assessment of their potential risks to soil organisms.

4.12.P-We393 Effects of Typical Pesticide Mixtures Representing European Agriculture on Soil Microbial Activity

Paula S. Tourinho, *Zuzana Bílková and Jakub Hofman, RECETOX, Masaryk University, Czech Republic*
Microbial activities play an essential role in the decomposition and cycling of nutrients, and therefore are a good bioindicator of the health status of soils. The aim of this work was to assess the effects of 11 pesticide mixtures on C and N mineralization. Pesticide mixtures were selected based on their occurrence in soils from 11 case study sites (PT-Portugal, SP-Spain, FR-France, CH-Switzerland, IT-Italy, HR-Croatia, SI-Slovenia, CZ-Czech Republic, NL-The Netherlands, DK-Denmark, and AR-Argentina), together with their ecotoxicological data retrieved from EFSA reports. Soils were spiked with the pesticide mixture at the median measured environmental concentrations (MEC), predicted environmental concentration (PEC), and 5 times PEC (5PEC). After 28 days of incubation, C mineralization was measured using basal respiration (BR) and substrate-induced respiration (SIR), and N mineralization was assessed as the potential of ammonification (PAMO) and potential of ammonia oxidation (PAO). If the measured endpoints in the pesticide-treated soils indicated deviation higher than ±25% from controls, the measurements were repeated in 28-day intervals (i.e., 56 and 84 days). Deviation from solvent control >±25% were observed in 6 out of the 11 mixtures after 28 days for at least one endpoint. For BR, the CZ mixture caused effects at PEC and 5PEC and PT mixture at 5PEC. In two treatments, PEC in PT and 5PEC in SP/IT mixtures, the differences were above the ±25% only when compared to the negative control. After 56 days, no effects were longer observed in any treatment, except in the PT mixture where deviation from control decreased to <25% only after 84 days. SIR showed deviation >25% at 5PEC in FR and CH mixtures after 28 days. After 56 days, the deviations from control were below ±25%. PAMO decreased at PEC and 5PEC exposures in the CZ and NL mixtures. After 56 days, only in CZ mixture were the deviations >25%, however effects were no longer present after 84 days. PAO was only affected in the CZ mixture at PEC and 5PEC, and after 56 days, no effect was observed. Although the effects on C and N mineralization persisted up to 56 days in the most toxic mixtures (CZ for C mineralization and PT for N mineralization), the microbial activity recovered after 84 days.

4.12.P-We394 Toxicity and Bioaccumulation of Realistic Pesticide Mixture in Earthworm-Plant-Soil Microcosm

Paula S. Tourinho, *Marek sudoma, Maria Janos kova, Zuzana Bílková and Jakub Hofman, RECETOX, Masaryk University, Czech Republic*

In this work, a microcosm experiment was conducted to assess the bioaccumulation in earthworms and plants and toxicity on earthworms, plants and microbes for realistic pesticide mixture. Five pesticides were selected based on the frequency of occurrence in agricultural soils from the Czech Republic and their risk to soil invertebrates retrieved from EFSA documents. The mixture contained azoxystrobin, boscalid, dimoxystrobin, lambda-cyhalothrin, and thiophanate-methyl. Three concentrations of the pesticide mixture were prepared in 4 replicates: the medians of the measured concentrations (MEC) of the 5 selected pesticides, the predicted environmental concentrations (PEC) initially occurring in soil after pesticide application as retrieved from EFSA documents, and 5 times PEC values (5PEC). Ten adult earthworms with developed clitellum and 8 pre-germinated lettuce seeds were added to each microcosm pot, containing 1 kg of moist soil. After 14, 28, and 56 days, 4 pots of each treatment were sacrificed. The number of survival earthworm, and the biomass of earthworms and lettuce leaves and roots were measured. Depurated earthworms and lettuce roots and shoots were collected for analysis. The microbial activity was measured as carbon and nitrogen mineralization. At 56 days, the number of earthworm juveniles and cocoons were counted. Earthworm survival was only affected at 5PEC, where 90% and 100% mortality were observed after 28 and 56 days, respectively. Earthworm biomass and reproduction significantly decreased at PEC and 5 PEC. No effect on lettuce biomass was observed. The basal respiration was the most sensitive endpoint for microbial activity, with effects observed at MEC, while for the other endpoints (i.e., substrate induced respiration, potential ammonification, and potential ammonium oxidation) were affected at PEC and/or 5PEC. The uptake kinetics in earthworms was modeled using a first-order one-compartment model. It showed a potential for bioaccumulation in earthworms for boscalid and dimoxystrobin, with bioaccumulation factors above 1 in all concentrations. In lettuce root, beside boscalid and dimoxystrobin, azoxystrobin also showed a potential for bioconcentration. Lettuce leaves, on the other hand, showed much lower bioconcentration potential, indicating a limited translocation from roots to leaf. This work highlights the impact of pesticide mixture exposure, as deleterious effects were observed at realistic concentrations, such as MEC and PEC.

4.12.P-We395 Simulated Pesticide Spray Regime in Five Cropping Systems on Soil Invertebrates: Effects of a Cumulative Pesticide Mixture on European Native Earthworms

*Violette Geissen[1] and **Olukayode Jegede**[2], (1)Soil Physics and Land Management, Netherlands, (2) University of California Davis, United States*

To protect the environment, pesticide risk assessment is conducted, but it is often based on single pesticide toxicity data. In agroecosystems, different pesticides are usually applied serially during growing seasons, leading to cumulative mixtures of pesticides in soil or other environmental matrices. Moreover, pesticides are registered based on the active substance, but formulations are applied in the field. It is, therefore, essential to know how pesticide formulations, following standard pesticide application patterns in the field, may cause mixture toxicity effects on soil biodiversity and ecosystem function. For our study, we exposed European native earthworm species (Lumbricus rubellus and Lumbricus terrestris) to pesticides based on pesticide spray schedule for five different cropping systems (CS). Glass jars of 500g, 50% water holding capacity (WHC) moistened soil in 5 replicates were prepared for each pesticide spray schedule for L. rubellus. For L. terrestris, an anecic and bigger-sized earthworm, glass framed mesocosms of 1.8 kg of 50% WHC moistened soil were prepared in 5 replicates. Dried horse manure mixed with oats were added as food for L. rubellus and litter made up of black poplar (Populus nigra) leaves were added as food on the soil surface for L. terrestris. To simulate a realistic field study, the recommended application rates of pesticide formulations were applied by spraying on the soil surface according to spray schedule on L. rubellus and L. terrestris for the duration ranging between 57 days to 98 days of the growing season typical to each CS. At the test end, relative to the control, the reproduction of L. rubellus was significantly impacted in all CS and the growth of L. terrestris was affected in all CS. Growth, mortality, and cast production of L. terrestris were consistently significantly impacted in a particular CS. The CS with the most pesticides applied carried more risk.

Disclaimer/Disclosure: European Union s Horizon 2020 research and innovation program under grant agreement No 862568 (SPRINT)

4.12.P-We396 Health Risk Assessment in Agricultural Areas: Case Study of the Statte Area

Valeria Ancona[1]*, Natalia Leone*[2]*, Annamaria Basile*[3] *and Vito Felice Uricchio*[1]*, (1)Construction Technology Institute/ Water Research Institute, Italian National Research Council, Italy, (2)Water research Institute, Italian National Reserach Council, Italy, (3)Waste Cycle and Reclamation Section - Puglia Region, Italy*

The characterization activity of some areas intended for agri-food production, located in the Territory of Statte (TA), conducted by the municipal administration of Statte in collaboration with the CNR of Bari, has highlighted exceedances of the legal limit reported in the Ministerial Decree 46/2019, for the organic micropollutant parameter (?PCDD + dioxin-like PCBs) in soil samples. Therefore, in accordance with the provisions of this environmental law, the Health Risk Assessment (HRA) connected to the contamination of the site was carried out, starting from the development of the Preliminary Conceptual Model (PCM). This is aimed at identifying the possible sources of contamination, hypothesizing the mechanisms and processes of transport of the contaminants, and identifying the targets and the relative methods of exposure to potential contamination, allowing to evaluate the risk conditions for human health and the environment. To this end, by relating the results of the previous characterization analyses and those deriving from the implementation of the recent characterization of the soils collected in the survey area, with the geological and hydrological structure of the site and the land use of the areas investigated, we proceeded to analyze the elements that define the PCM and, therefore, to produce a preliminary health and environmental HRA. To assess the risk associated with the consumption of agri-food products from the agricultural areas of interest, specific monitoring criteria and sampling protocols were defined for plant biomass and agri-food products which, in consideration of the prevalent use of the land, involved vineyards and olive groves. Based on the analytical results of the agri-food products (grapes and olives), we then proceeded to assess the risk associated with their consumption, developing a risk assessment according to the methods set out in Annex 3 of the Ministerial Decree (46/2019). The health risk assessment, conducted for the grape and olive samples, highlighted that the risk deriving from the presence of the substances investigated is acceptable. These preliminary results are encouraging and do not highlight significant risks to human health following the intake of these agri-food products.

4.12.P-We397 Sustainable Integrated Management of Soil Nematode Control- The Responsibility of Choices

Maura Calliera[1]*, Andrea Minuto*[2]*, Nicola Aiezzo*[3]*, Diego Voccia*[4] *and Ettore Capri*[4]*, (1)Opera Research Centre Universit Cattolica Sacro Cuore Piacenza, Italy, (2)CeRSAA Centro di Sperimentazione e Assistenza Agricola, Italy, (3)Teleos Ag Italia, Italy, (4)Universit Cattolica del Sacro Cuore - Piacenza, Italy*

Italy is characterized by a high marked value agro-industrial system, that relies on high value, quality and technological production, with increasing attention to sustainability. An agriculture that, however, still requires significant use of production factors as pesticides, which must be properly managed. This is particularly true in soil-borne parasitic nematodes control that, despite several proposed alternatives, still

rely on chemicals as soil fumigants, due to their impact and severe losses in high value crops grown under intensive growing system. Current legislation, which mandates sustainable agriculture, does not impose the choice of strategy to be employed, leaving farmers with the responsibility to decide within a wide range of possibilities. However, the sustainable use of fumigants, given the complexity of the subject, the great uncertainty on the effectiveness of alternative treatments to chemicals, due to the lack of eradicant effect and, for high value crops, the scale of investments required, necessitates a multi-stakeholder approach involving various parties beyond just farmers, including both private sector and public entities. The proposal of this work is the production of a document agreed upon by multiple parties, that outline needs and critical issues, summarizes key ideas, and suggests necessary actions that could serve as a valuable tool for decision-makers, encouraging them to consider and support all effective solutions and techniques to achieve the European objectives regarding soil fumigants risk reduction and exposure, through proper implementation of IPM. To this end, a multi-phase approach combing several levels of information (1-consultation, to gather data with qualitative interview, 2- engagement, for sharing data, expert perspective and knowledge, 3-feedback) is proposed, following also the Expert Knowledge Elicitation EFSA guidance. The goal is to acquire qualitative data on how issues related to limiting and/or better targeting fumigant use against major soil-borne pathogens, are addressed by users, to develop and suggest strategies and tools for better and more effective management and communication regarding environmental and human s risk. The initiative emphasizes sustainable integrated nematode management as a cornerstone for achieving this goal. Results will feed a shared position paper aimed at facilitating dialogue among stakeholders, ensuring that diverse perspectives are included in decision-making processes

Disclaimer/Disclosure: This paper was produced in the frame of Ph.d. in Agro-food system (AGRISYSTEM)-XXXVIII Cycle

4.12.P-We398 Mind the Gap: Balancing the Need for Regulatory Safety and Sustainability of Crop Protection Products

***Ola Dosunmu*[1]**, *Sian Ellis[2] and Andrew Sweetman[1], (1)Lancaster University, United Kingdom, (2)Corteva Agriscience, United Kingdom*

Crop Protection Products (CPP) play an important role in agriculture by protecting crops from pests and maintaining crop yield, hence supporting the United Nations Sustainable Development Goals (SDGs) in promoting global food security.

In the EU, pesticides are regulated under Regulation (EC) No. 1107/2009 (EC 2009) which sets approval criteria to ensure human health and environmental safety. Though this regulation addresses safety, which is a key sustainability criterion, it does not explicitly address other aspects of sustainability or include additional incentives for more sustainable elements to be adopted in the design of crop protection products. However, recommendations on the use of CPP are provided in the Sustainable Use Directive (Directive 2009/128/EC) but their implementation and enforcement are uneven across the EU.

As the EU advances initiatives like the Green Deal and the Farm to Fork Strategy, there is a growing emphasis on sustainable agriculture. However, without clear sustainability criteria for crop protection products, it remains challenging to guide the development of products that are both safe and sustainable. Manufacturers typically focus on regulatory compliance and the registrability of agrochemicals during development of a product. However, having well defined sustainability criteria, would promote the adoption and incorporation of other sustainable attributes. This could also be supported by clear business incentives for manufacturers to ensure products meet defined sustainable advantages to accelerate investment into these product types.

To address this, we propose criteria for consideration when (re)designing agrochemicals based on the principles of the EU Safe and Sustainable by Design (SSbD) and additional criteria specific to the use and function of plant protection products, for discussion. These criteria include efficacy, reduced exposure, green chemistry principles , agronomic justification, compatibility with integrated pest management (IPM) and sustainable farming systems e.g. soil health. Establishing such criteria can help guide agrochemical development towards a future that aligns with EU policies and the UN SDGs, fostering resilient and sustainable agricultural practices.

4.12.P-We399 Effects of Realistic Pesticide Mixtures on Wheat (Triticum Aestivum) And Lettuce (Lactuca Sativa)

Paula S. Tourinho *and Jakub Hofman, RECETOX, Masaryk University, Czech Republic*
As primary producers, terrestrial plants are the base of the food web, producing energy for other trophic levels. Moreover, terrestrial plants are also responsible for providing habitat and shelter to other organisms and, in the case of leguminous plants, for hosting nitrogen-fixing bacteria. This work aimed to assess the effects of realistic pesticide mixtures to terrestrial plants using the soil as the exposure route to mimic the toxicity of soil residues. For each mixture, 5 pesticides were selected based on their risk to terrestrial plants (values retrieved from EFSA reports) and their frequency of occurrence in agricultural soils from 10 European countries (Portugal, Spain, France, Switzerland, Italy, Croatia, Slovenia, Czech Republic, The Netherlands, and Denmark) and Argentina. Root growth inhibition test (ISO 11269-1) and seedling emergence and growth test (OECD 208) were conducted with wheat (Triticum aestivum) and lettu ce plants (Lactuca sativa). Three concentrations were used: median measured environmental concentration (MEC), predicted environmental concentration (PEC), and 5 times PEC (5PEC). The data was analyzed by a Kruskal-Wallis test, followed by a Dunn s post hoc test to compare the concentrations to the control. In wheat, root growth was the most sensitive endpoint, and a significant decreased compared to control was observed in 10 out of the 11 mixtures. In lettuce, biomass of seedling was the most sensitive endpoint with significant effects in 9 mixtures. Considering both species, significant effects in root growth or seedling biomass were observed at the MEC level in 4 mixtures (France, Switzerland, Slovenia, and The Netherlands). Significant effects on seedling emergence were observed at PEC level in 7 mixtures (Spain, Italy, Czech Republic, The Netherlands, and Argentina). The effects were species-specific and endpoint-specific, which can be related to the different mixture composition and mode of action of the herbicides in the mixtures. For instance, the mixtures that affected seedling emergence had microtubule assembly inhibitors (e.g., propyzamide, pendimethalin), or synthetic auxins (e.g., Mecoprop P and 2,4-D). Effects occurring at MEC indicate that the presence of multiple pesticide residues in soil is an important route of exposure to be considered.

4.12.P-We400 Towards Improved Risk Management to Reduce Chemical Pressure on Biodiversity in Europe

Dorte Themann[1]*, Marlene Ågerstrand*[2]*, Nikiforos Alygizakis*[3]*, Johan Axelman*[4]*, Yann Devos*[5]*, Guy Duke*[3]*, Sabine Duquesne*[1]*, Peter Fantke*[3]*, Romana Hornek-Gausterer*[6]*, Paola Movalli*[7]*, Susan Oginah*[8]*, Laura Scherer*[9]*, Jaroslav Slobodnik*[3] *and Gabriele Treu*[1]*, (1)German Environment Agency (UBA), Germany, (2)Stockholm University, Sweden, (3)Environmental Institute, Slovakia, (4)Swedish Chemicals Agency (KemI), Sweden, (5)European Food Safety Authority (EFSA), Italy, (6)Environment Agency Austria, Austria, (7)Naturalis Biodiversity Center, Netherlands, (8)Technical University of Denmark, Denmark, (9)Leiden University, Netherlands*
Risk management (RM) is a core element of the different European chemical regulations (REACH, CLP, pesticides and pharmaceuticals). RM describes a process of identifying and implementing measures to prevent or reduce an environmental risk. At the same time, chemical pollution has become one of the greatest threats to biodiversity. There is already a discussion on how to better integrate the protection of biodiversity into environmental risk assessments (ERAs). What has not been discussed so far is the role that RM can play in the goal of better protecting biodiversity.
One challenge in answering this question lies in the fact that firstly, different understandings and procedures of RM exist (e.g. in terms of scope, principles, strategies, instruments, etc.). Secondly, the different chemical regulation systems do not have the same RM structures and procedures and use different types of risk management measures (RMM). Based on scientific literature and the concept of risk governance, we first propose a definition and characterization of RM and a distinction between different types of RMM. This provides a first descriptive analytical lens for characterizing the current RM structures and procedures. To deepen the analytical perspective towards gaps and problems in preventing the loss of biodiversity and identification of possible improvements of the implemented RM systems, the Biodiversity Policy Integration approach is used to analyze the current RM systems regarding the integration of biodiversity in a conceptual and procedural way.
Based on this analytical framework, we will take an explorative problem-oriented approach by using qualitative empirical social research methods. These include a document analysis as well as expert interviews with various stakeholders related to the different RM systems under consideration. We strive to unravel the RM logics, the practices of how RMM are applied and to identify problems in procedural and structural terms to avoid biodiversity loss and reduce pollution. By doing so, we will identify current challenges and gaps more systematically and identify possible intervention points for improvement. The overall aim of this poster is to present our analysis on the RM systems in a holistic way in the first place. Based on this basic review, we illustrate steps for systemic improvement and outline specific novel measures.

Disclaimer/Disclosure: This poster has received funding from the EU-funded project TerraChem From soils to apex species: chemical pathways, effects and impacts on terrestrial biodiversity and ecosystem services and applications for better chemicals management (project number: 101135483).

4.13 Advances in Risk Assessment for Plant Protection Products With a Non-conventional Mode-Of-Action

4.13.T-01 Problem Formulation for the Risk Assessment of Low-Concern Pesticides

In response to the European Green Deal and the Sustainable Use Directive the European authorities have introduced measures to reduce the use of chemical pesticides, and to encourage the introduction in the market and use of non-chemical pesticides. Non-chemical pesticides include those based on microorganisms and non-living substances such as Low-Concern Active Substances (LCASs; i.e., substances which are expected to be of low concern). However, the regulatory framework of LCASs is based on the framework for conventional synthetic active substances and plant protection products. Harmonised guidance on how to make this framework more appropriate and efficient for LCAS is lacking in most cases.

In the EFSA-funded project entitled Develop a stepwise approach for a fit-for-purpose risk assessment, in particular for low-concern active substances and uses our consortium has developed a risk assessment scheme based on Problem Formulation (PF) and Pathways to Breach the Protection Goal (PBPG) model. For this scheme, generic PBPG were drawn up for each combination of a hazard and protection goal. This scheme can be applied to all types of LCAS due to its inherent flexibility and aims to harmonise the approach for the assessment of LCAS. The scheme was applied to case studies representing the main types of LCASs (botanicals, semiochemicals, microbial metabolites, inorganics, peptides and dsRNA).

The proposed problem formulation method using PBPG can be used at any stage of the risk assessment. During the pre-submission stage it can be used to determine the overall approach for the risk assessment, including which type of data is needed (e.g., literature data, guideline testing, customised testing). At this stage, upon generating this data, the problem formulation step can be repeated to include the new information and in this way determine the most appropriate next step (whether it s needed to generate further data or not). At the evaluation stage, the approach can be applied to the assessment regardless of whether the approach was used at the pre-submission stage. Also, the approach helps to present the outcome of the risk assessment in a transparent way, thereby facilitating risk communication with risk managers and stakeholders.

4.13.T-02 RNAi as a Novel Mode of Action of Plant Protection Products: How to Assess Risks for Soil Invertebrates?

Anja Coors[1], *Sonja Brauer*[1], *Adam Scheffczyk*[1], *Mirco Weil*[1], *Athanasios Dalakouras*[2] *and Khalid Amari*[3], *(1)ECT Oekotoxikologie GmbH, Germany, (2)ELGO-DIMITRA, Institute of Industrial and Forage Crops, Greece, (3)Julius Kuhn Institut, Germany*

In the context of the European Green Deal, an increase in the development and market authorisation of sustainable low-risk plant protection products is a key factor. A natural origin of the active ingredient is often proposed as a possible way forward in this context. The mechanism of RNA interference (RNAi) by double-stranded RNA (dsRNA) is a natural post-transcriptional gene silencing process which is conserved in eukaryotes. The first dsRNA-based plant protection product has been authorized in the U.S. in 2023. This product targets Colorado potato beetles, which is also a major pest species in Europe. Consequently, the first product with dsRNA as active ingredient is up for seeking marketing authorisation in the European Union. The present contribution addresses the assessment of potential effects of dsRNA on soil invertebrates, a standard non-target organism group that needs to be considered in the environmental risk assessment in the European Union. The conceptual approach that we developed and followed will be presented and discussed. The first steps of the conceptual approach have already been completed by selecting the target dsRNA as well as (assumed) negative and positive reference dsRNA. Due to high gene sequence homology, the collembolan species Folsomia candida was selected in the present case as the most suitable soil NTO, and oral uptake was identified as the most relevant exposure route. The first tests following an adapted protocol of the standardized collembolan reproduction test have been completed with reference dsRNA and tests are ongoing with target dsRNA. While effects were observed on the reproduction of the collembolans, it is currently under investigation whether they relate indeed to sequence-specific RNAi-mediated processes, or rather reflect other pathways of toxicity.

Disclaimer/Disclosure: Acknowledgement This work has received funding from the European Union s Horizon Europe Research and Innovation program under Grant Agreement No. 101084163 (RATION). We thank particularly Genolution Inc., Korea, for providing specifically synthesized dsRNA within the frame of the RATION project.

4.13.T-03 The Effects of a Microorganism-Based Plant Protection Product on a Simple Aquatic Ecosystem

Judith Epping *and Paul van den Brink, Aquatic Ecology and Water Quality Management Group, Wageningen University, Netherlands*

Plant protection products (PPPs) utilizing microorganisms as active ingredient are considered promising alternatives to conventional pesticides due to their natural occurrence in the environment and attributed species specificity. These strains often do not show direct toxicity effects to standard aquatic test organisms, but information on their fate in water or sediment and their effects on aquatic environments, including the microbial community, remains limited. Additionally, it was reported that microbial pesticides may increase turbidity, potentially reducing light availability and affecting primary production, with cascading effects to the aquatic community. This study aimed to assess the direct and indirect effects of a PPP containing Bacillus amyloliquefaciens strain FZB42 on aquatic organisms and their interactions in an indoor microcosm setting. We hypothesized that the pesticide would not have direct toxic effects on ecosystem structure and function, but expected increased turbidity, altered microbial community, and indirect effects on the feeding of Gammarus pulex at high pesticide concentrations. The experiment involved three different treatments (1x or 4x application of the max. recommended dose and 1x application of 10x max. recommended dose) and three different controls (negative, filtered and deactivated) over four weeks. Measured endpoints included respiration, macrophyte biomass, microbial decomposition, phytoplankton chlorophyll-a, zooplankton and microbial community composition, macroinvertebrate survival and feeding, and abiotic parameters (nutrient levels, EC, pH, oxygen, and temperature). The microcosms were highly productive, resulting in low nutrient concentrations, increasing pH and high dissolved oxygen levels. Contrary to our hypotheses there were no significant differences in microbial decomposition, macroinvertebrate feeding, or turbidity across treatments. Two key endpoints, zooplankton and microbial community composition, have not been evaluated yet. The findings from this microcosm experiment provide new insights into the effects of microorganism-based PPPs on aquatic ecosystems, which can be implemented to improve the risk assessment and determine the focus points compared to conventional, synthetic pesticides. Indirect effects on microbial community or productivity of aquatic ecosystems may prove to be more relevant than classic, direct toxicity endpoints.

4.13.T-04 Microbial Biopesticides are Inhibited by the In Vitro Diet Used in Larval Honey Bee Laboratory Bioassays

Daniel R Schmehl[1]*, David Larsen*[2]*, Camille Gomez*[3]*, Vanessa Roeben*[4] *and Lisa S. Ortego*[1]*, (1)Bayer AG, Crop Science Division, United States, (2)Ginkgo Bioworks, United States, (3)MilliporeSigma, United States, (4)Bayer AG, Crop Science Division, Germany*

Royal jelly is a substance secreted by the hypopharyngeal glands of worker honey bees and is the primary component of the in vitro honey bee larval diet according to the OECD 239 test guidance. Royal jelly is a complex and nutrient-rich substance yet has several bioactive properties that may create barriers for the testing of microbial-based plant protection products. While establishing the safety of these materials is as important as for conventional chemicals, there are important distinctions between them. For example, microbes must be evaluated for their pathogenic potential because some microbes are known to only affect the larval stage of bees (e.g., Paenibacillus larvae, American Foul Brood). For characterizing microbial inhibition from in vitro larval diet, five microbes were grown on agar plates and the in vitro larval bee diet was spotted on the plates. Inhibition tests revealed that the diet inhibited the growth of some of the bacteria and fungi, including the known bee pathogen Paenibacillus larvae. This work highlights the need for considering adaptations to current standardized approaches, which may include prework to confirm whether the test material is inhibited when integrated into the royal jelly-based in vitro larval diet.

4.13.P-Th338 An RT-qPCR-Based Protocol for the Detection and Quantification of dsRNA Pesticides

Venetia Koidou[1], *Minlee Kim*[2], *Dimitrios G. Karpouzas*[3], *Kalliope K. Papadopoulou*[3] *and Athanasios Dalakouras*[4], *(1)ELGO-DIMITRA, Institute of Industrial and Forage Crops, Greece and University of Thessaly, Greece (2)Genolution Inc, Democratic People's Republic of Korea, (3)University of Thessaly, Greece, (4)ELGO-DIMITRA, Institute of Industrial and Forage Crops, Greece*
Double stranded RNA (dsRNA) pesticides, triggering RNA interference (RNAi) of selected targets, have recently emerged as an effective and eco-friendly solution to the challenges posed by climate change and the urgent need for sustainable agriculture. To assess the environmental fate of dsRNA pesticides, a sensitive, precise and versatile method for its detection and quantification is needed. Here, we report on a RT-qPCR protocol developed to tackle obstacles related with dsRNA s detection and quantification in complex matrices as soil, where both degradation and adsorption may complicate the interpretation of results. At first, the protocol is optimized for an in vitro quantification of dsRNA, using treatments to reduce interference associated with non-functional nucleic acids, such as DNA or single stranded RNAs, that may be present either in the dsRNA product or in the environment. Next, a multi-step protocol was applied in soil samples to facilitate the dsRNA recovery, after its adsorption to soil particles. Furthermore, when chitosan-based formulation was tested, it was shown to not interfere with its RT-qPCR detection. The proposed method may easily be adapted to suit any dsRNA sequence and can be employed for ecological risk assessment and regulatory evaluations.

4.13.P-Th339 Microbial Effects on Honeybees: Impact of the Use of Pollen in the Diet of Honeybee's Survival in a 10-day Laboratory Chronic Oral Toxicity Test Prolonged to 30 Days

Benedetta Ponti[1], *Erica Tediosi*[1], *Claudia Ferrario*[1], *Aneta Karolin Gron*[2] *and Stefano Magni*[3], *(1)LabAnalysis Life Science, Italy, (2)University of Milan, Italy, (3)Biosciences, University of Milan, Italy*
Among non-synthetic plant protection products, microbial biopesticides represent more sustainable methods for pest management. These biocontrol agents are usually considered as safe for non-target species, such as pollinators. To date, specific ecotoxicological protocols to test their effects are still not available, even if a prolonged observation time after exposure is sometimes required (e.g. 30 days, OPPTS). The standard diet (sucrose solution) proposed by the current guidelines doesn t permit to achieve bees survival for more than 18 days. The lifespan in honeybees is strongly influenced by diet, especially regarding the content in proteins. Therefore, the best diet to keep bees alive for 30 days was investigated. In particular a preliminary experiment was carried out to assess the benefits of two different sources of proteins: pollen and synthetic essential amino acids (EAAs).
Our results demonstrated that a diet enriched with pollen guarantees an increase in honeybees survival. The 20% of organisms fed with only sucrose solution (50% w/v) died after 18 days. The mortality of honeybees fed with EAAs was 23.3 % after 15 days (EEAs 1:500), 23.3 % after 22 days (EEAs 1:250) and 20% at 14 days (EEAs 1:50). The mortality of honeybees fed with pollen was 10 % after 30 days. Based on these preliminary results, the impact of microbial biopesticide on honeybees was investigated by comparing the effects observed in organisms fed with only sucrose solution and honeybees fed also with pollen ad libitum. The test without pollen addition allowed to determine an EC50 after 20 days equal to 61.7 x 108 CFU/mL while the test performed with pollen addition showed an EC50 respectively equal to > 405 x 108 at 20 days and equal to 366.5 x 108 CFU/mL after 30 days.
In this context, our results showed also a clear improvement in honeybees' survival in laboratory conditions (OECD 245, OPPTS) when feeding with a diet enriched with pollen. Furthermore, a mitigation of the negative effects was recorded by comparing the EC50 obtained from both exposure routes. In conclusion, the current methods for evaluating microbial pesticides are not optimized, especially when prolonging the observation after 20 days. The development of standardized tests that can be used as lines of evidence in assessing the likelihood of adverse effects of microbial pesticides on bees is of particular interest and should be investigated further.

4.13.P-Th340 Risk Assessment Innovation for Low-Risk Pesticides with Caenorhabditis elegans as Ecotoxicological Model

Xupeng Yu *and Nico van den Brink, Wageningen University, Netherlands*
Current pesticide risk assessment protocols in the EU are primarily designed for chemical pesticides, with limited standardized approaches for low-risk pesticides. This study evaluates the impacts of three low-risk pesticides-- double-stranded RNA (dsRNA) targeting the Proteasome subunit beta 5 (PSMB5) in Colorado potato beetle (CPB), pelargonic acid (PA), and Bacillus amyloliquefaciens-- on the activity and development of Caenorhabditis elegans, as measured by WMicrotracker ONE. Our results showed that

dsRNA exposure rather than producing species-specific effects acting upon target genes, triggers a general immune response at high concentrations (>5 μg/ml) causing delayed development and/or lower activity. PA exhibited the observable effect at field-use concentrations and showed an increased impact in the second generation, suggesting a potential for long-term influence. Moreover, C. elegans displayed lower activity level even at low exposure of B. amyloliquefaciens (0.04 μl/ml), implying possible interference with natural organisms. These findings underscore the necessity for customized assessment protocols for low-risk pesticides and highlight C. elegans as a suitable model organism for sustainable pest management risk assessment.

4.13.P Advances in Risk Assessment for Plant Protection Products With a Non-conventional Mode-Of-Action

4.13.P-Th338 An RT-qPCR-Based Protocol for the Detection and Quantification of dsRNA Pesticides

Moreover, C. elegans displayed lower activity level even at low exposure of B. amyloliquefaciens (0.04 µl/ml), implying possible interference with natural organisms. These findings underscore the necessity for customized assessment protocols for low-risk pesticides and highlight C. elegans as a suitable model organism for sustainable pest management risk assessment.

4.13.P-Th341 Environmental Risk Assessment of RNAi-Based Plant Protection - A Literature Review

Udo Hommen[1]*, Kerstin Derz*[1]*, Elke Eilebrecht*[1]*, Kirsten Germing*[1]*, Andreas Schiermeyer*[1]*, Sebastian Eilebrecht*[1] *and Mathias Otto*[2]*, (1)Fraunhofer Institute for Molecular Biology and Applied Ecology (IME), Germany, (2)BfN, Germany*

Applications using the molecular mechanism of RNA interference (RNAi) are relatively new types of plant protection. The effect of RNAi is primarily based on a reduction in the expression of essential genes of the target organism, which is triggered by ingested double-stranded RNA (dsRNA) as the actual active ingredient. In such RNAi-based approaches, a distinction is made between endogenous and exogenous applications. Endogenous application means the production of the dsRNA in genetically modified plants (GMPs) and is also called host-induced gene silencing. In exogenous applications, dsRNA is used as an active ingredient in plant protection products. In most cases these are sprayed onto crops, which is also known as spray-induced gene silencing. The poster will present the results of one work package of a project commissioned by the German Federal Agency for Nature Conservation (BfN) on Environmental effects of RNAi-based GM plants and methods for transient modification of organisms. In the specific work package, we aim to determine the status quo of environmental risk assessment of RNAi-based GMPs and plant protection products and to identify existing gaps. The overarching complexes such as (1) the stability of dsRNA in the environment, (2) its uptake in in non-target organisms, (3) its effects on non-target organisms as well as (4) the consequences of similarities and differences between endogenous and exogenous application for risk assessment will be addressed. Available environmental risk assessments of the US EPA for an RNAi based crop and an RNAi spray are summarized and compared to EU requirements for plant protection products.

4.13.P-Th342 Transcriptome Analysis of RNAi Spray Effects on the Aquatic Invertebrate Daphnia magna as a Non-Target Model Organism

Katharina Knapp[1]*, Kirsten Germing, Cecilia Diaz, Kwang-Zin Lee, Sebastian Eilebrecht and Elke Eilebrecht, Fraunhofer Institute for Molecular Biology and Applied Ecology (IME), Germany*

RNA interference (RNAi)-based pesticides represent a novel class of pesticides with a distinct chemical structure compared to conventional pesticides. Categorized as biopesticides, they are expected to have a reduced environmental impact and minimal effects on non-target organisms. RNAi is a post-transcriptional gene silencing process that naturally occurs in eukaryotic organisms, leading to sequence-specific suppression of gene expression in the target organisms. Gene silencing can affect growth, cause developmental defects, and can lead to mortality. The RNAi pathway suppresses gene expression in pests by inducing sequence-specific silencing through mRNA degradation via siRNA. This suggests that RNAi-based pesticides have little to no effect on non-target organisms and degrade rapidly in the environment due to the low stability of RNA molecules. However, this assumption is yet to be proven, as current risk

assessment may need adaptation to the molecular nature of RNAi pesticides.
The aim of this project is to assess whether a new designed RNAi-based pesticides affect the non-target organism Daphnia magna. In the first phase, acute tests with D. magna following OECD Guideline 202 are conducted. Juvenile D. magna are exposed to three different substances: 1) a RNAi-based spray formulation containing dsRNA targeting the p300 mRNA of aphids; 2) a RNAi-based spray formulation containing dsRNA targeting the Green Fluorescent Protein (GFP) and 3) the conventional pesticide flonicamid. The RNAi-based pesticide is the experimental substance on the field. The GFP formulation serves as a control. Any potential effects on Daphnia observed with the pesticide can be attributed to the spray formulation or dsRNA. Flonicamid, which has a similar mode of action to RNAi in aphids, will allow for a comparison of modes of action with the RNAi-based pesticide.
In the second phase, the acute tests will be repeated with a sublethal concentration range and the RNA of the exposed organism will be extracted. In order to identify the Mode of Action of the substances, a whole genome expression analysis of the RNA level will be conducted.
In the third phase, a method for concentration analysis of the dsRNA in the test medium via qPCR will be developed. In addition, the sequence homologies of the P300dsRNA in D. magna will be assessed via NCBI BLAST. This will help draw conclusions regarding the effects observed in the acute toxicity tests with the RNAi-based pesticide.

4.13.P-Th343 Impact of dsRNA-based Plant Protection Products on Aquatic Organisms

***Judith Epping**, Ruoying Song and Paul van den Brink, Aquatic Ecology and Water Quality Management Group, Wageningen University, Netherlands*

Plant protection products (PPPs) with new, non-conventional modes-of-action provide a promising alternative to currently widely used synthetic pesticides. An emerging novel crop protection opportunity is the use of double-stranded ribonucleic acid (dsRNA). PPPs with dsRNA as active substance utilize the RNA interference mechanism by targeting specific genes to disrupt crucial physiological functions in the development, metabolism or reproduction of the pest or pathogen. Bioinformatic screening allows to design dsRNA sequences and consequently PPPs that are highly species specific. Additionally, dsRNA has a short degradation time in environmental matrices, which could minimize its impact on non-target organisms compared to conventional synthetic pesticides. In practice, little data is available about the effects of dsRNA on aquatic organisms. The objective of this research is to determine whether dsRNA affects standard aquatic test species and to which extent current test guidelines need to be adapted to assess their sensitivity to this PPP with non-conventional mode-of-action. Three different dsRNA sequences will be tested, one targeted at a common pest (Colorado Potato Beetle, CPB, PSMB5 gene), one negative control (green fluorescent protein, GFP) and one positive control sequence with a highly conserved gene (actin). All dsRNA will be tested in four concentrations ranging from 0.025 mg/L to 25 mg/L on four different test species, including Daphnia magna, Chironomus riparius, Hyalella azteca and an aquatic beetle (to be determined). Testing will closely follow OECD test guidelines 202 (Daphnia), 235 (Chironomus) and 321 (Hyalella) with an extended observation period of 96h. Mortality and immobility will be recorded at 24, 48 and 96h. RT-qPCR will be used to monitor dsRNA concentrations over time. We hypothesize that the PSMB5 and GFP gene sequences will not affect the different test organisms due to their species specificity and non-essential nature, respectively. As a positive control, we expect the dsRNA sequence targeting actin to also affect aquatic organisms. The results of this study will provide insights into the impact of dsRNA-based PPPs to aquatic organisms. The findings will also support the advancement of a risk assessment adjusted to the requirements of the novel, non-conventional mode-of-action of this group of PPPs.

4.13.P-Th344 Environmental Risk Assessment of RNA Interference Based Pesticides

***Hannah-Philine Dey**[1], Susanne Bar[2], Esther van der Zalm[2], Kristin Hirte[2], Sebastian Eilebrecht[3], Elke Eilebrecht[3], Kwang-Zin Lee[3] and Henner Hollert[4], (1)German Environment Agency (UBA); Fraunhofer IME; Goethe University Frankfurt, Germany, (2)German Environment Agency (UBA), Germany, (3)Fraunhofer IME, Germany, (4) Goethe University Frankfurt; Fraunhofer IME, Germany*

Currently novel pesticides are being developed on the basis of the biological process of RNA interference. Their mechanism of action differs significantly from that of chemically synthesized and other biological pesticides. A double-stranded RNA (dsRNA) is used, which is designed to be homologous to a sequence segment of the messenger RNA (mRNA) of a protein that is vital for the target organism. Through processing in the organism and the molecular biological process of RNA interference (RNAi), the mRNA is either degraded or its translation into the encoded protein is inhibited, resulting in the death of the target organism. To date, one RNAi-based pesticide has already been approved by the USEPA.
Due to the sequence specificity of the mechanism, RNAi pesticides are supposed to be highly specific and thereby should have no adverse effects on non-target organisms. Thus, they could contribute to a

sustainable plant protection. However, there are still many open questions and data gaps regarding the potential environmental risk of such substances. Whether adverse effects actually occur in non-target organisms, is not yet sufficiently understood and depends, among other things, on exposure, bioavailability and actual specificity. Due to the properties and modes of action of RNAi pesticides, both the data requirements and the risk assessment criteria for the EU authorization of chemically synthesized or biological pesticides are not appropriate and applicable to them and need to be adapted and/or newly developed. This project is intended to contribute closing the knowledge gaps and developing accepted data requirements and guidelines for authorization.
To address these challenges the first phase of the project intends to identify how different formulations of the dsRNAs can change the bioavailability for different organisms. We aim to develop a standard protocol for a positive and negative control to test the bioavailability of differently formulated dsRNAs for standard non-target organisms. Transcriptome analysis will be applied to assess potential off-target effects of the formulated dsRNA in the non-target organism. The project will contribute to evaluating whether the standard organisms for the risk assessment at hand are sufficient to evaluate RNAi pesticides.
The results of this project will contribute to the definition and development of adapted data requirements and guidelines for EU authorization of RNAi pesticides.

4.13.P-Th345 Assessing the Toxicity of Orange Assential Oil (d-limonene) on Soil-Dwelling Springtails (Folsomia candida)

***Anna Huang**, Bastian H. Polst, Steven Droge, Arrienne Master and Gertie Arts, Wageningen Environmental Research, Netherlands*

Plant extract products, such as essential oils, are increasingly used as plant protection products offering an alternative to conventional synthetic pesticides. Among these, orange oil, primarily composed of d-limonene, is one of the most produced essential oils globally. When sprayed on crops for their protection, orange oil is likely to also reach the soil, exposing soil organisms to d-limonene through ingestion of contaminated food and contact with pore water and soil particles containing residues post-application. Lethal effects of the formulated product have been reported by EFSA for non-target (above ground) arthropods (NTAs), within a factor of two above the application rate, but showed no risk to earthworms. However, the potential effects of orange oil products on other soil organisms remain largely unexplored. In our preliminary study, we investigated the acute toxicity of orange oil to the soil-dwelling springtail Folsomia candida. The experiment was conducted in closed jars containing 30 g of Lufa soil. We applied the formulated product (60 g/L, approximately 95% d-limonene) to the soil and added 20 adult individuals per replicate across three doses: control, 25 mg/kg soil, and 250 mg/kg soil, with four replicates for each treatment. The jars were sealed after setup, and the experiment lasted 7 days. Results showed less than 10% mortality in the control group, approximately 50% mortality in the 25 mg/kg treatment, and 100% mortality in the 250 mg/kg treatment. Our preliminary results indicate that orange oil is toxic to soil organisms, with an LC50 value of 25mg/kg soil; additionally, the EFSA dossier reports a predicted soil concentration of 4.18 mg/kg.
Our results highlight the need for comprehensive future studies to fully assess the environmental impact of orange oil, including chronic endpoints related to reproduction. In addition, studies should examine effects on other NTAs and plants using a holistic approach that accounts for the chemical's properties, such as high volatility. For example, researchers could spray orange oil on soil and focus on deposition on non-target plant parts like stems and leaves, as well as its cumulative effects on soil organisms and non-target terrestrial species. Moreover, the difficult chemical properties of d-limonene, such as low water solubility, high sorption, and high volatility, must be considered, as they complicate chemical analysis and exposure quantification.

4.14 Pharmaceuticals in the Environment Innovations in Risk Assessment, Regulation, and the Science Globally

4.14.T-01 Assessing the Environmental Sustainability of Human Medicinal Products: A Proposed Medicinal Product Sustainability Index (MPSI)

***Jason Snape**[1] and Caroline Moermond[2], (1)University of York, United Kingdom, (2)RIVM, Netherlands*

There are increased global concerns about the continued presence of pharmaceuticals in the environment and the risk that these residues of active pharmaceutical ingredients (APIs) pose to wildlife and human health. Whilst the environmental hazards and risks of human medicinal products (HMPs) are assessed as part of their marketing application they are not a barrier to market approval for HMPs. The environmental exposure, and their wider environmental impacts, are not limited to the patient use of these medicinal products. Pollution can occur at the point of bulk drug manufacture and formulation resulting in hot spots of API exposure where insufficient industrial wastewater treatment and dilution is in place. Improper disposal of unused or expired medicinal products can also be a source of APIs into the environment. However, if we think about environmental sustainability in its widest sense API production is resource inefficient (<<1%); most small molecule APIs have a process mass intensity (PMI; Kg of raw material used to make a Kg of API) of between 100-1000. For large molecule APIs like monoclonal antibodies (mAb) the PMI is on average 7700 Kg raw material per Kg mAb. Once registered the manufacturing process is rarely updated to improve its environmental sustainability over time. Healthcare contributes to c.5% of global greenhouse gas emissions (GHG), making it one of the largest sectors contributing to global warming. Healthcare providers are starting to explore frameworks for green procurement of HMPs. Many of these procurement initiatives are focused on comparing GHG footprints of HMPs to help reduce their Scope 3 GHG footprint. This presentation proposes a wider sustainable procurement approach and advocates for a medicinal product sustainability index (MPSI) that captures (i) GHG emissions along the entire value chain, (ii) water intensity along the entire value chain, (iii) water scarcity risks in the supply chain, (iv) water quality and pollution risks at the point of manufacture and formulation, (v) natural resource efficiency at a process and dose level, (vi) environmental hazards and risks of the API, (vii) the use of substances of very high concern (SVHCs) in the manufacturing process and excipients, and (viii) extended producer responsibility commitments. The MPSI will be based on simple metrics that allows environmental sustainability performance data to be compared within and across pharmaceutical classes.

4.14.T-02 Using High Resolution Mass Spectrometry Non-Target Screening Data to Detect Exposure Patterns of Pharmaceuticals in German Rivers

***Anna Lena Kronsbein*[1]**, *Ronya Mona Wallis[1], Eric Rosenheinrich[1], Silke Hickmann[1], Arne Hein[1], Kevin S. Jewell[2], Arne Wick[2] and Jan Koschorreck[1], (1)UBA (German Environment Agency), Germany, (2)BfG (German Federal Institute of Hydrology), Germany*

The increasing presence of pharmaceuticals in freshwaters poses risks to aquatic ecosystems health and challenges the regulatory frameworks. This study investigates the utility of high-resolution mass spectrometry (HRMS) non-target screening (NTS) portals in the detection of pharmaceutical mixtures and supports pharmaceutical legislation and Early Warning Systems. In line with EU strategies such as the Chemicals Strategy for Sustainability, we integrate HRMS NTS data into monitoring programmes using the German NTS portal. The German NTS portal, developed by the German Environment Agency (UBA) and the Federal Institute of Hydrology (BfG), contains HRMS NTS data of surface water and suspended particulate matter (SPM) samples from the German Environmental Specimen Bank collected over two decades and enables retrospective and trend analyses.

The NTS portal uses spectral libraries for secure substance annotation, which improves usability by the authorities. It utilises a spectral library of over 1600 substances, of which around 30 % are pharmaceuticals. We analyse spatial and temporal trends of pharmaceuticals, highlighting ubiquitous exposure patterns such as for metoprolol and seasonal trends such as for clarithromycin. The combination of quantified HRMS-NTS data with predicted no-effect concentrations (PNEC) enables the calculation of risk quotients and the identification of toxic drivers that can be used in prioritization.

We compare the risk quotients of pharmaceuticals with other substance groups such as persistent organic pollutants (POPs) and provide insights into the environmental exposure of pharmaceuticals on the EU Water Framework Directive Watch List.

Strong correlations between market volumes of pharmaceuticals and concentrations in the environment highlight the need of including production data in prioritization efforts. Reliable PNECs derived from the authorisation procedure improve the interpretation of water monitoring data and risk assessment. By making the data FAIR and accessible to authorities, the NTS portal contributes to the understanding of pharmaceutical mixtures in aquatic environments and thus to effective chemical regulation and environmental protection.

4.14.T-03 Fate of Pharmaceuticals in Aquatic-riparian Food Webs at Sites Receiving Municipal Wastewater Discharges

*John Fast and **Karen A. Kidd**, McMaster University, Canada*

Many classes of pharmaceuticals are regularly detected in surface waters downstream of wastewater treatment plants (WWTPs) and they may be bioaccumulated by larval aquatic insects and transferred to riparian predators through insect emergence from aquatic ecosystems. This study quantified the concentrations of active pharmaceutical ingredients (APIs) and select metabolites in aquatic insects and a family of riparian spiders that relies heavily on aquatic insect prey to assess the fate of APIs in downstream ecosystems impacted by WWTP effluents. Aquatic larval and terrestrial adult insects representing different functional feeding groups and nearshore spiders were collected three times in the summer of 2022 upstream and downstream of four WWTPs along the Grand River, southern Ontario, Canada. A modified QuEChERS method with matching internal standards was developed and is being used to compensate for interferences across multiple taxa and life stages. Sixteen pharmaceutical targets and select metabolites, which may also pose a risk to aquatic life, were selected for analysis and include antidepressants, anticonvulsants, antibiotics, and anti-inflammatories commonly detected in surface waters. Six APIs (Carbamazepine, Fluoxetine, Ibuprofen, Venlafaxine, Triclosan, Diclofenac) and 6PPD-q were consistently (>50% detection rate) found in larval insects from the family Hydropsychidae at all sites, and levels were higher in insects collected downstream than upstream of the points of discharge. Selected major metabolites for parent compounds were not detected above method detection limits within most sites or taxa. Larval insects total body burden (ΣAPIs) ranged 180 230 ng/g ww across all sites. Adult insects collected during emergence events, after metamorphosis has occurred, had lower body burdens of APIs (15 28 ng/g ww) than their larval forms but also higher concentrations and a greater diversity of contaminants in samples from downstream sites. Spiders had similar profiles of APIs as larval insects, but ΣAPIs (54 103 ng/g ww) were lower in spiders than aquatic larvae suggesting potential differences within riparian spiders aquatic diet or an increased rate of depuration. Overall, results support the movement of APIs from aquatic to terrestrial ecosystems via emergent insects, and highlight the importance of more complete food web studies to better understand the export of aquatic APIs to terrestrial predators with a varied diet of aquatic prey.

4.14.T-04 Assessing the Suitability of Recent EU Environmental Quality Standards that Account for the Ecotoxicity and Prevalence of Transformation Products

***Lucy Kennelly**, Graham Merrington, Dean Leverett, Rhiannon Smith and Sylwia Kosmala-Grzechnik, wca environment Ltd, United Kingdom*

Environmental Quality Standards (EQSs) are key regulatory tools in Europe for assessing potential chemical risks and controlling discharges to the water environment. The European Commission s (EC) recent EQS Proposal includes EQS for two pharmaceutical substances, carbamazepine and clarithromycin. The derivations for both substances account for transformation products (TPs), which is relatively unusual for EQS derivations in Europe. The derived EQS for clarithromycin has been modified based on available ecotoxicity data for its TPs, whilst for carbamazepine the EQS is for the sum of the parent substance and metabolites measured in exposure data.

Here, we review the EC s EQS derivations for carbamazepine and clarithromycin to assess the suitability of the approaches for accounting for the TPs, comparing these approaches to the guidance and the available scientific evidence. For each substance, we identified any additional relevant and reliable ecotoxicity data on the parent compound and its TPs. We then derived deterministic freshwater EQS values and investigated where probabilistic approaches could be applied, including how to incorporate TP data into this approach.

Based on our review of the EC s EQS dossiers and our own derivations, we developed a roadmap for the incorporation of TP data into the derivation of EQSs for contaminants of emerging concern. The roadmap indicates how TP data could be considered based on its availability, relevance, reliability, and ecotoxicity and prevalence compared to the parent compound.

Based on an evidence-driven review of the EQS derivations for clarithromycin and carbamazepine and thorough assessment of the consideration of TP data, we reached the following conclusions: Some, but not all, contaminants of emerging concern have relevant and reliable data on their TPs which may need to be considered for EQS derivation.

Ecotoxicity and monitoring data on TPs are often scarce. Obtaining additional data on TPs would allow a more comprehensive evaluation of their hazards and exposure potential.

As the need to consider TPs is likely to become more common in regulatory assessments, it highlights the need to implement a coherent and consistent approach for how to incorporate TP data into such assessments and the derivation of evidence-driven and environmentally relevant limit values.

4.14.T-05 A Tiered Secondary Poisoning Risk Assessment Approach to Prevent Unnecessary Fish Bioaccumulation Testing of Pharmaceuticals

***Gemma Janer**[1], Joanne Elmoznino[2], Andreas Haener[3], Samuel K Maynard[4] and Irene Bramke[5], (1)Novartis, Spain, (2)Pfizer, United States, (3)Roche, Switzerland, (4)Environmental Protection, Global Sustainability and SHE, Operations, AstraZeneca, United Kingdom, (5)AstraZeneca, Netherlands*

Secondary poisoning risk assessment is a new requirement under the revised EMA guideline on environmental risk assessment of pharmaceuticals. The guideline triggers a fish bioaccumulation study when the logDow of the substance exceeds 3 at an environmentally relevant pH (5 to 9). When the resulting bioconcentration factor (BCF) is ≥100 L/kg, a secondary poisoning risk assessment is needed. Inputs for the calculation of secondary poisoning potential are fish BCF, chronic mammalian toxicity data, and the estimated concentration of API in surface waters. Extensive mammalian toxicity data and reliably conservative surface water exposure estimates are already available by the time a secondary poisoning risk

assessment is triggered. Therefore, we propose a modification to the secondary poisoning risk assessment approach prescribed by EMA, whereby the relevant mammalian toxicity data and guideline-compliant conservative exposure estimates are leveraged in order to determine the need for a fish bioaccumulation study, and to allow a conclusion on potential secondary poisoning risk.
In a first step, a worst-case secondary poisoning risk quotient is calculated using the equations described in the EMA guideline, but replacing the experimental BCF value with a conservative default BCF value based on exiting, recently published datasets (Constantine et al., 2024; Gimeno et al., 2024;). These proposed default BCF correspond to the highest/percentile P95th values of available pharmaceuticals and other chemicals with logDow values comparable to that of the substance to be assessed. If the outcome of this preliminary step is a risk quotient below 1, conducting a fish bioaccumulation study would not be justified. On the other hand, a preliminary risk quotient (RQ) >1 derived in this manner would show the need for a substance-specific fish BCF to inform the secondary poisoning risk assessment.
For compounds yielding preliminary RQs around 1, additional sources of information, such as in vitro mammalian clearance data obtained during drug development, in vitro fish clearance data (e.g., OECD TG 319), or evidence for dose accumulation in preclinical studies, could further inform on the likelihood of a risk of secondary poisoning.
Several real examples are provided to illustrate this concept, and which, most importantly, highlight how a considerable amount of unnecessary fish testing could be avoided.

4.14.P Pharmaceuticals in the Environment Innovations in Risk Assessment, Regulation, and the Science Globally

4.14.P-Tu363 Integrating Predictive Modelling and Wastewater-Based Epidemiology for Comprehensive Environmental Risk Assessment of Pharmaceutical

Kishore Kumar Jagadeesan[1]*, Like Xu*[1]*, Nicola Ceolotto*[1]*, Lottie Newton*[1]*, Megan Robertson*[2]*, Ruth Barden*[2] *and Barbara Kasprzyk-Hordern*[1]*, (1)Environmental Chemistry and Public Health Research Group, University of Bath, United Kingdom, (2)Wessex Water, United Kingdom*
This study presents an innovative approach to environmental risk assessment (ERA) of pharmaceuticals by combining wastewater-based epidemiology and predictive modelling. The research addresses key challenges in API risk assessment, including the lack of quality hazard and exposure data, and the need for improved methodologies in predicting environmental concentrations.
The study utilized prescription data from England's National Health Services to predict pharmaceutical concentrations in wastewater influent/effluent and river. The study focused on pharmaceuticals across different therapeutic classes. Initial concentrations (PEC) of pharmaceuticals, which were then validated against measured environmental concentrations (MEC) from two wastewater treatment plants in Southwest England.
Key findings include: Accuracy of PEC predictions was assessed using the criterion (0.5<PEC/MEC<2) which reflects a close alignment between PEC and MECs: For influent, accurate predictions for 12 of 33 pharmaceuticals at site A and 15 of 33 at site B. For effluent, it is 11 of 28 pharmaceuticals at site A and 13 of 28 at site B. For river, it is 11 of 26 pharmaceuticals across both sites.
When PEC and MEC were used to rank the detected pharmaceuticals based on risk, generally both the approaches provided similar ranking, and this provide some confidence in the use of PEC in risk assessment of the pharmaceuticals.
The study also conducted a comprehensive ERA by calculating RQs using both predicted and measured concentrations, as well as PNEC-ENV and PNEC-MIC values. This approach allowed for a more holistic assessment of environmental risks across different trophic levels.
Results showed varying levels of environmental risk across different pharmaceuticals and trophic levels. Some compounds, like metronidazole, presented low risk, while others, such as clarithromycin and trimethoprim, consistently showed high risk. The study highlighted the importance of considering both PNEC-ENV and PNEC-MIC values for a comprehensive ERA approach.
The study underscores the need for refined predictive tools and standardized ERA procedures to address the environmental impact of pharmaceuticals in aquatic ecosystems. It also emphasizes the importance of monitoring data to improve the accuracy of risk assessments for specific regions, aligning with the session's focus on integrating the best available science and strategic approaches to managing APIs in the environment.

4.14.P-Tu364 Suspect Screening of Pharmaceutically Active Compounds in River Ecosystem by High-Resolution Mass Spectrometry

*Silvia Royano, **Juan Escobar Arnanz**, Irene Navarro, Adrian De La Torre and María Ángeles Martinez, CIEMAT, Spain*

Most of freshwater ecosystems in developed countries receive pharmaceutically active compounds (PhACs) from wastewater treatment plants (WWTPs), exposing them to the toxic effects these pollutants can cause. In this study, an analytical methodology based on Ultra High-Performance Liquid Chromatography coupled to High-Resolution Mass Spectrometry (UHPLC-QTOF HRMS) was developed to perform a suspect screening analysis to identify PhACs present in the river ecosystem. In this way, a more complete picture of the current PhAC contamination situation can be obtained, overcoming the limitations of target analysis methods.
173 samples were collected during 2020, 2021 and 2022 along the Tagus River basin (Spain) ecosystem: 89 surface river waters, 28 river sediments, 24 fish and 32 samples from WWTPs. WWTP samples comprised both wastewater and sewage sludge to qualitatively assess potential PhACs removal and water-sludge partition occurring during the treatment.
MS and MS/MS data following the chromatographic separation were registered in ESI positive ionization mode using data-independent acquisition. Identification criteria were based on more than a 75% match with libraries, a maximum accurate mass error of 5 ppm, and an isotopic pattern difference below 20%. Furthermore, only features with an intensity ten times higher than the blank intensity were considered. More than 100 PhACs were identified across all samples with a level of confidence of 2a according to Schymanski s scale.
Among all identified PhACs, the main therapeutic groups were psychiatric drugs (e.g., amisulpride), anti-inflammatories (e.g., diclofenac), analgesics (e.g., tramadol), and cardiovascular drugs (e.g., telmisartan). Surface water samples presented more than 20 PhACs identified in over 50% of the samples. Up to 54 compounds were identified in river sediments with detection frequencies between 4% and 61%. Fish was the matrix with the lowest number of PhACs identified and detection frequencies <35%. At least 60 PhACs were identified in wastewater samples revealing the transfer of some of these contaminants since more than 50 compounds were found in sewage sludges with detection frequencies up to 80%. Transformation products resulting from drug metabolism were also explored, and metabolites of the antiepileptic carbamazepine and the hypnotic zolpidem were the most frequently detected (>55%).

Disclaimer/Disclosure: The present study is part of the project PID2019-105990RB-I00 funded by MICIU/AEI/10.13039/501100011033.

4.14.P-Tu365 Spatiotemporal Dynamics and Ecological Risks of Pharmaceuticals and Personal Care Products in Korean Rivers

Jun Yub Kim *and Sang Don Kim, Gwangju Institute of Science and Technology, Republic of Korea*

Pharmaceuticals and personal care products (PPCPs) are emerging contaminants of concern due to their pseudo-persistence in aquatic environments, resulting from continuous release and incomplete removal during wastewater treatment. This study investigated the occurrence, seasonal dynamics, and ecological risks of 137 PPCPs in four major Korean rivers Han, Geum, Yeongsan, and Nakdong over a one-year period from April 2020 to March 2021.
Water samples were collected monthly from 22 sites across the four rivers. PPCPs were analyzed using liquid chromatography-high resolution mass spectrometry (LC-HRMS). The ecological risks of PPCP mixtures were assessed by calculating the Risk Quotients based on the Sum of Toxic Units (RQSTU) for fish, crustaceans, and algae.
Of the 137 targeted PPCPs, 120 were detected, with 98 quantified above the limit of quantification. Concentrations varied significantly across seasons and rivers, ranging from a few ng/L to 42.7 µg/L for metformin. The highest mean summed concentration was observed in the Yeongsan River (22.5 µg/L), followed by Han (12.4 µg/L), Nakdong (11.9 µg/L), and Geum (10.9 µg/L) rivers. However, when considering total load based on monthly flow rates, the Han River contributed the highest pharmaceutical flux (607.7 kg/day), significantly exceeding other rivers.
Seasonal analysis revealed the highest concentrations in winter (20.5 µg/L), followed by spring (18.5 µg/L), summer (10.7 µg/L), and fall (10.1 µg/L). This pattern suggests reduced dilution during base flow conditions in winter and spring, contrasting with increased dispersion during summer and fall flood events.
Median seasonal RQSTU values were 5.4, 4.5, and 3.5 for fish, crustaceans, and algae, respectively, indicating moderate to high ecological risks. Seasonal analysis revealed the highest risks in spring, followed by fall, winter, and summer. This pattern suggests that certain high-risk PPCPs are less influenced by seasonal variations or flow conditions than overall concentrations.
This study highlights the importance of integrating spatiotemporal dynamics in PPCP risk assessments. The findings provide valuable insights for developing targeted monitoring and management strategies to mitigate ecological impacts in freshwater ecosystems, especially during high-risk seasons.

Disclaimer/Disclosure: This work was supported by Korea Environment Industry & Technology Institute (KEITI) through Development of target/suspect/nontarget screening method for analysis of micropollutants and unknown substances, funded by Korea Ministry of Environment (MOE) (No. 2019002710005) and by GIST Research Institute (GRI) grant funded by the Gwangju Institute of Science and Technology (GIST) in 2023.

4.14.P-Tu366 Pharmaceutical Contamination in European Groundwater and Drinking Water

*Martin Hansen, **Annaliese Vernon**, Mulatu Nanusha and Hans-Jorgen Albrechtsen, DTU, Denmark*

Pharmaceuticals and their transformation products are especially relevant Contaminants of Emerging Concern (CECs) due to their engineered bioactivity and their widespread presence in diverse environments. Pollution from pharmaceutical compounds has been detected in drinking water, and its precursor in Denmark and many other locations; groundwater. Understanding the chemical exposome related to consistent low-level contamination by pharmaceuticals in aquatic matrices is crucial due the potential toxicological implications and the ubiquitous nature of this exposure, even for vulnerable groups. With this goal in mind, this study first aims to summarize the extent of pharmaceutical pollution in European drinking and groundwater by compiling data from studies that have detected such compounds via two principle analytical methods, Gas Chromatography-Mass Spectrometry (GC-MS) and Liquid Chromatography-Mass Spectrometry (LC-MS). This study reports concentration ranges and detection frequency and dives into analysis of key pharmaceuticals, including carbamazepine, ibuprofen, diclofenac, sulfamethoxazole, metformin and phenazone. To further expand understanding of the chemical exposome, the study will analyse drinking water samples from Denmark using non-target analysis. LC-MS/MS will be utilized due to its high sensitivity and ability to distinguish between co-eluting compounds with the same molecular masses but different product ions. This technique will be used with spectral libraries to enable the probable identification of a wide array of compounds, providing broad insight into pharmaceutical contaminants. This approach aims to minimize research bias that could lead to the frequent detection of commonly identified compounds, thereby offering a more comprehensive exposure assessment and identifying additional chemicals of interest. Additionally, a toxicological perspective will be included as QSAR modelling and machine learning will be utilized to make relevant toxicological predictions, contributing to preliminary risk assessment. Overall, this study will contribute to the current understanding of the pollution load of pharmaceuticals in Danish drinking water and groundwater, giving a better picture of the human exposure to these compounds and their implications for human health. This research can serve to inform decisions regarding pharmaceutical regulation, pollution management, or water treatment optimization, to ensure the safety of this vital resource.

4.14.P-Tu367 Evaluation of Environmental Risks Posed by Pharmaceutically Active Compounds in the Great Bačka Canal

***Maja Buljovcic**, Jelena ivancev, Igor Antic, Dusan Rakic and Natasa Durisic-Mladenovic, University of Novi Sad, Faculty of Technology Novi Sad, Serbia*

The assessment of risks linked to the occurrence of pharmaceutically active compounds (PhACs) in aquatic environments has become a significant concern due to their potential impact on ecosystems and human health. The extent of PhACs presence in the Great Bačka Canal, known as one of the most polluted waterways in Europe, is not known, even though it is impacted by the unregulated discharge of various contaminants of emerging concern either from agricultural runoffs, wastewater effluents, or various industrial activities. This study aims to assess the risks associated with the presence of PhACs in the Great Bačka Canal through an evaluation of their concentration levels, and potential ecotoxicological effects. Forty surface water samples were collected along the Great Bačka Canal and analysed for a range of commonly used pharmaceuticals, including antibiotics, anti-inflammatory drugs, antidepressants, beta blockers, anti-epileptics, and lipid regulators. The ecological risk evaluation of detected PhACs was estimated based on the technical guidance document on risk assessment released by the European Commission. According to the mentioned document, the RQ risk model was assessed by the maximum environmental concentration (MEC) of individual pharmaceuticals measured in the surface water of the Great Bačka Canal divided by the predicted no-effect concentrations (PNEC) of pharmaceuticals. The risk posed to aquatic organisms was categorized into three levels: $RQ < 0.1$, low risk; $0.1 \leq RQ < 1$, moderate risk; $RQ \geq 1$, high risk. The findings indicate varying levels of pharmaceutical occurrence, with some compounds exceeding threshold concentrations known to cause ecological risk. The results underscore the need for improved wastewater treatment practices and the establishment of more stringent regulations to mitigate the impact of PhACs on the aquatic environment of the Great Bačka Canal. Furthermore, this research enhances the understanding of the environmental risks posed by pharmaceutical pollutants in freshwater systems, especially those used for crop irrigation.

Disclaimer/Disclosure: Acknowledgement - This research was supported by the Science Fund of the Republic of Serbia, #GRANT No. 7335, Sustainable environmental monitoring and prediction of pollutants spread EnviLife.

4.14.P-Tu368 Assessing the Environmental Risk of Pharmaceuticals in the Italian Waters: An Integrated Approach

*Stefano Polesello[1], Marianna Rusconi[1], Vitalia Murgia[2], Luisa Mattoli[3], Mattia Gianni[3], Giada Fodaroni[3], Giacomo Bonacina[3], Grazia Carmela Ferrara[3], **Sara Valsecchi**[4] and Emiliano Giovagnoni[3], (1)CNR-IRSA, Italy, (2)Associazione Italiana Medici per l'ambiente ISDE Italia, Italy, (3)Aboca SpA, Localit Aboca, AR, Italy, (4)Water Research Institute - Italian National Research Council (IRSA-CNR), Italy*

Environmental risk assessment (ERA) of pharmaceuticals is an essential process aimed at safeguarding our ecosystems from potential harm caused by medicines. The present project aimed to assess the environmental risk of pharmaceuticals in Italian waters by using two complementary approaches.
On one hand we assessed the environmental potential risk by collecting physico-chemical characteristics and (eco)toxicological data for more than project 300 compounds used in pharmaceutical products (such as APIs, preservatives, artificial sweeteners, dyes as well as some selected stable metabolites). The list of substances has been created by a prioritization process that involves the collection of actually measured drugs in Italian waters, the official consumption data and expert judgments of medical specialists from various therapeutic sectors. The data have been collected from different databases and they have been organized in technical sheets. A scoring system has been developed in order to calculate a presumed level of potential environmental risk for each substance, which is intrinsic to the molecular structure and independent from the geographical consumption or diffusion.
On the other hand, we planned to measure the actual concentrations of the listed substances in the Italian surface, ground and drinking waters, by sampling more than 100 site along the Italian peninsula aiming to cover the variety of water body geographical typologies, pollution pressures and water uses. The availability of measured concentrations will allow to calculate the site-specific risk using the risk quotient approach as the ration between measured concentrations (MEC) and PNEC of specific end-points.
The integration of database of concise fact sheets and site specific risk evaluation is the basis to develop a web-based application which can be freely consulted by health professionals in order to raise awareness on the environmental risks of pharmaceuticals preparations for doctors and pharmacists involved in drug prescriptions or recommendations.

Disclaimer/Disclosure: Project funded under the National Recovery and Resilience Plan (NRRP), Mission 4 Component 2 Investment 1.4 - Call for tender No. 3138 of 16 December 2021, rectified by Decree n.3175 of 18 December 2021 of Italian Ministry of University and Research funded by the European Union NextGenerationEU;
Award Number: Project code CN_00000033, Concession Decree No. 1034 of 17 June 2022 adopted by the Italian Ministry of University and Research, CUPB83C22002930006, Project title National Biodiversity Future Center - NBFC .

4.14.P-Tu369 Pharmaceutical Removal Via Anaerobic Digestion in Different Wastewater Matrices: Kinetic Assessment, Ecotoxicological Effects and Biotransformation Products

***Matheus Neves de Araujo**[1], Allan Pretti Ogura[1], Elias Gabriel Fernandes de Rezende[1], Carolina Nemeth Comparato[2], Elis Watanabe Nogueira[1], Thiago Vinicius Ribeiro Soeira[1], Vinicius Silveira Leite[1], Lucas Tadeu Fuess[1], Pedro Sergio Fadini[3] and Marcelo Zaiat[1], (1) University of Sao Paulo (USP), Brazil, (2)University of Sao Paulo (USP) / Federal University of Sao Carlos (UFSCar), Brazil, (3) Federal University of Sao Carlos (UFSCar), Brazil*

While municipal and hospital wastewaters (MW and HW) share similar input sources, primarily from sanitary effluents, their compositions differ significantly, especially in terms of organic matter, nutrients, and contaminants of emerging concern. Many studies use synthetic wastewater (SW), often rich in standard carbohydrates and proteins, to control experimental conditions. However, comparisons between synthetic and real wastewater matrices are scarce. This study assessed anaerobic digestion performance for eight pharmaceuticals (acetaminophen-ACT, atenolol-ATN, caffeine-CAF, carbamazepine-CBZ, diclofenac-DCF, ibuprofen-IBU, naproxen-NPX, and propranolol-PRP), biomethane production, ecotoxicological effects and biotransformation products across MW, HW, and SW matrices. Batch bioreactors were used with uniform agitation, temperature, and food-to-microorganism ratio. Biogas evolution, chemical oxygen demand (COD), and target compound levels were periodically monitored. Pharmaceuticals products were analyzed using tandem mass spectrometry and biotransformation products (TPs) via high-resolution mass spectrometry. Acute ecotoxicity tests were conducted on C. silvestrii and D. similis under varying dilutions (100, 50, 25%) before and after treatment. Methane production followed

a sigmoidal pattern for SW and MW, while HW showed a linear trend. Maximum methane production and production rate were highest for SW, followed by MW and HW. Variations in substrate concentrations likely influenced these outcomes, with HW exhibiting significantly lower COD levels compared to MW and SW. The presence of diverse pharmaceuticals, especially antibiotics in HW, may further inhibit methane production. Macro-nutrient (carbohydrates and proteins) removal efficiencies were higher for SW compared to MW and HW. Differences in initial macro-nutrient levels likely contributed to these trends, with SW exhibiting significantly higher carbohydrate and protein concentrations. CAF and NPX exhibited zero-order kinetic decay for CAF in SW, MW and HW. ACT followed a first-order decay pattern. Other compounds (ATN, CBZ, DCF, IBU, and PRP) showed no removal. TPs are under analysis. Ecotoxicity tests revealed C. silvestrii to be more sensitive than D. similis, with higher toxicity observed in SW compared to real matrices. Despite providing controlled conditions, the simplicity and higher ecotoxicity of SW underscore the need for caution when extrapolating findings to real wastewater matrices.

Disclaimer/Disclosure: This study was sponsored by the Fundação de Amparo à Pesquisa do Estado de São Paulo (FAPESP) [grants numbers: 2020/09912-6, 2022/01945-8, and 2021/14789-1] and nanced in part by the Coordenação de Aperfeiçoamento de Pessoal de Nível Superior - Brasil (CAPES) - Finance Code 001.

4.14.P-Tu370 Ecotoxicological Response of Lichens to Pharmaceuticals in the Terrestrial Environment

***Gintare Sujetoviene**, Diana Miškelytė, Austra Diksaityte, Giedre Kaciene, Irena Januskaitiene and Jurate Zaltauskaite, Vytautas Magnus University, Lithuania*

Environmental pollution with pharmaceutical preparations, which are necessary for the maintenance of human and animal health, is becoming one of the most important environmental problems. Currently, many pharmaceutical active substances are used for the treatment or prevention of diseases in humans and animals. Due to their widespread use and persistence, antibiotics have become an important group of emerging contaminants that are increasingly being studied. The ecological risks posed by antibiotics are a growing concern and require increasing research attention. However, the prevalence of veterinary antibiotics in the environment and their effects on the environment are still poorly studied. The study aimed to evaluate the ecotoxicological effects of antibiotics on non-target organisms - lichens. Toxicity of tetracycline (TC), ciprofloxacin (CIP) and sulfamethoxazole (SMX) was tested based on physiological and biochemical lichen responses. The study results showed that mycobiont and photobiont reacted to different antibiotics indicating dose- and time-dependent toxicity. The study highlighted the response of symbiotic organisms to exposure to toxic environments.

4.14.P-Tu371 Assessing Environmental and Endocrine Risks of Diclofenac Liposome Encapsulation and Its Byproducts

***Carolina Machado**[1], Iria Naveira-Souto[2], Madalena Vieira[1], Patrícia Veríssimo Silva[1], Maria D Pavlaki[1], Elisabet Rosell-Vives[3] and Susana Loureiro[1], (1) University of Aveiro, Portugal, (2) Universidad Nacional Autonoma de Mexico, Spain, (3)Laboratorio Reig Jofre, S.A., Spain*

The increase of pharmaceuticals in the environment, mainly due to inadequate disposal and inefficient removal in wastewater treatment plants, has raised concerns about their potential effects on ecosystems and human health. To approach this problem, new methodologies, such as the encapsulation of compounds that allow a more controlled release at the site of action, are being developed to reduce their environmental impact across their life cycle. This study aimed to evaluate the effects of a novel liposomal encapsulation of diclofenac, as well as the impact of production residues, namely diafiltration waste, on different organisms, while also testing a commercial diclofenac solution for comparison. To this end, an acute toxicity test with Aliivibrio fischeri (Microtox), a Yeast Estrogen Screen Assay (YES) and an acute immobilisation test with Daphnia magna (OECD 202), were conducted. Microtox results demonstrated effects on the bioluminescence produced by A. fischeri in all samples, with the final product, diafiltrated liposomes loaded with diclofenac, being the one with the highest effect, with an EC50=3.45mg/L. In agreement with this, the results obtained for D. magna demonstrated lower survival rates from the diafiltrated sample with an EC50=26.16mg/L. On the other hand, the commercial diclofenac solution induced the lowest effects in both organisms, with an EC50=15.09mg/L and EC50=144.32mg/L, for A. fischeri and D. magna, respectively. The results from the YES assay suggested that the final product and the placebo liposomes may have potentially induced endocrine disruption, as they were able to bind to the estrogen receptor in the yeast. Even though this new method may solve a current problem, in this case, liposomal encapsulation of diclofenac showed higher toxicity than the commercial formulation, suggesting that the process may affect the targeted and non-targeted delivery of the compound.

4.14.P-Tu372 Developments Towards a Marine Environmental Quality Standard (EQS) for Diclofenac

Dean Leverett[1], *Lucy Kennelly*[1], *Thomas Austin*[2], *Richard John Maunder*[3], *Daniel Hill*[3], *Cameron Hird*[4] *and Pete Johnson*[3], *(1)wca environment Ltd, United Kingdom, (2)Haleon, Switzerland, (3)Scymaris Ltd, United Kingdom, (4)Plymouth University, United Kingdom*

Diclofenac is a nonsteroidal anti-inflammatory human and veterinary medicine widely detected in European surface waters. Proposed Environmental Quality Standards (EQS) which include an assessment of toxicity to aquatic organisms have been proposed by the European Commission (EC) to support the aims of the Water Framework Directive (WFD) (EC 2022).

As part of the development of the chronic ecotoxicity dataset for diclofenac, originally intended to support this EQS derivation, a programme of new testing was established. This comprised a series of new GLP studies using freshwater and marine invertebrates with primary objectives of filling clear taxonomic gaps in the long-term aquatic effects dataset for diclofenac.

The marine element of this testing programme comprised four GLP studies, covering the effects on diclofenac on the reproductive performance of three echinoderm species (two sea urchins Paracentrotus lividus, Psammechinus miliaris and a starfish Asterias rubens) and a polychaete annelid (lugworm Arenicola marina). The sea urchin studies investigated the effect of diclofenac on the fertilisation of embryos and their subsequent development, following an acute exposure of adult animals immediately prior to spawning of gametes, while the remaining studies focused on fertilisation only. All four studies were performed at the Scymaris laboratory in Brixham, UK and were conducted according to the principles of Good Laboratory Practice. The detailed test parameters and results of these four studies will be presented in the poster.

In addition, we will consider an updated reliable and relevant long-term marine ecotoxicity dataset for diclofenac including these new data, and propose potential approaches to developing a marine EQS which focuses specifically on effects in saltwater organisms. Finally, the outcomes will be compared with the marine EQS proposed by the EC (based on effects in freshwater organisms) and discuss the level of protection afforded by the different EQS.

4.14.P-Tu373 A Framework for Interdisciplinary Environmental Risk Assessments of Antibiotics: From Patient to the Environment

Qiyun Zhang[1], *Jessica Amorim*[2], *Pieter-Jan De Sutter*[1], *Morten Suk*[3], *Klaus Kummerer*[3], *Tiina Sikanen*[2] *and Karel De Schamphelaere*[1], *(1)Ghent University, Belgium, (2) University of Helsinki, Finland, (3) Leuphana University Luneburg, Germany*

Benign by design concept promotes reducing the adverse impacts of chemicals from the beginning of their initial design stages. In light of this concept, the European Union project TransPharm (grant agreement number: 101057816) is dedicated to developing greener pharmaceutical molecules and their production processes to foster towards a more sustainable European pharmacy sector. In this study, we developed a framework for an interdisciplinary environmental risk assessment (ERA) to evaluate the influence of fluoroquinolones (FQs) currently on the market, as well as their derivatives developed within TransPharm, on the aquatic environment. This framework integrates both experimental methods, including bacterial growth inhibitory test and cyanobacteria toxicity test, and modelling tools such as the physiologically based pharmacokinetic model PK-Sim and probabilistic risk assessment. It aims to combine various aspects associating with the fate of antibiotics, such as antibiotic efficacy, pharmacokinetics in the human body, degradation pathways influencing persistence, with ecotoxicology, to offer an approach for selecting pharmaceuticals that can bridge human health benefits and environmental sustainability. Our results indicate that higher degradability enabled the FQ-derivative ciprofloxacin-hemi (CIP-hemi) to show a lower environmental risk quotient (RQ) in surface waters than ciprofloxacin (CIP) when prescribed at the same dosage level. In addition, intravenous administration was predicted to result in a lower risk compared to oral administration. However, the antibiotic efficacy of the derivative restricts its applicability. Although the RQ for CIP-hemi remained consistently below the risk threshold, it could completely achieve efficacy criteria for Escherichia coli ATCC 25922 only. For other strains tested, efficacy criteria was reached at relatively high dosages ≥ 400 mg every 12 hours.

4.14.P-Tu374 Improving Monitoring and Environmental Risk Assessment of Pharmaceuticals, Antimicrobial Resistance and Pathogens from Terrestrial to Aquatic Environments

Stephane Pesce[1], *Emilie Egea*[1], *Nat lia Corcoll*[2], *Benoit Cournoyer*[3], *Delphine Delaunay*[4], *Benoit Ferrari*[5], *Federico Ferrari*[6], *Helena Guasch*[7], *Dimitrios G. Karpouzas*[8], *Adrian Love*[9], *Alexandra Meziti*[10], *Victoria Osorio*[11], *Lorenzo Proia*[12], *Mechthild Schmitt-Jansen*[13], *Albert Sorolla*[14], ***Paul Thomas***[15] *and Chloe Bonnineau*[1], *(1)French National Research Institute for Agriculture, Food and Environment, France, (2)University of Gothenburg, Sweden, (3)National Centre for Scientific Research, Microbial Ecology*

Research Unit, France, (4)Foundation evertea, France, (5)Swiss Centre for Applied Ecotoxicology, Switzerland, (6)Aeiforia srl, Italy, (7)Center for Advanced Studies of Blanes - Spanish National Research Council, Spain, (8)University of Thessaly, Greece, (9)AquaBioTech Limited, Malta, (10)SmallOmics, Greece, (11)Institute of Environmental Assessment and Water Research - Spanish Council for Scientific Research (IDAEA-CSIC), Spain, (12)Fundacio Universit ria Balmes, Spain, (13)Helmholtz Center for Environmental Research (UFZ), Germany, (14)Naturalea Conservacio S.L, Spain, (15)KREATiS, France
Global contamination of soil and aquatic ecosystems by pharmaceutical and microbiological pollutants (such as antimicrobial-resistant microorganisms and/or pathogens) raises severe concerns about impacts on ecosystem health and repercussions on humans and animals. Preserving ecosystems from adverse ecotoxicological effects of pharmaceuticals and their transformation products and limiting the environmental spread of antimicrobial resistance and pathogens is imperative to reach several UN Sustainable Development Goals as well as the European Green Deal, Water Framework Directive and Biodiversity Strategy for 2030. To meet these huge environmental and societal challenges, public and private stakeholders and EU policy makers require improved monitoring and Environmental Risk Assessment to protect microbial diversity and functions in contaminated ecosystems. In this context, the MSCA Doctoral Network Pharm-ERA funded by the European Union (Grant Agreement 101119261) proposes a high-level interdisciplinary and intersectoral research and training network based on 10 doctoral projects covering scientific disciplines including environmental and analytical chemistry, microbial ecology, ecotoxicology, molecular biology (including multi-omics approaches) and chemical fate/effect modelling. Pharm-ERA involves 9 Beneficiaries (including 2 non-academics) and 6 Associated Partners (including 5 non-academics), committed to contribute to research, training, dissemination, communication and exploitation of results targeting end-users such as Environmental consultancies and agencies. Pharm-ERA will provide EU with high-level scientific experts who will further shape and implement the next generation of environmental management strategies, EU guidelines and regulations to reduce the adverse environmental effects and risks of pharmaceuticals and the spread of antimicrobial resistance and pathogens in terrestrial and aquatic environments. This will ensure sustainability of our ecosystems, fostering positive impacts on human and animal health and well-being far beyond the Pharm-ERA project.

4.14.P-Tu375 Assessing Reliability and Applicability of In Silico Tools for Chronic Aquatic Ecotoxicity of Human Pharmaceuticals

Cristiana Cannata *and Ad Ragas, Radboud University, Netherlands*
Residues of active pharmaceutical ingredients (APIs) and their metabolites have been detected in surface waters, raising increasing environmental concerns over time. Since 2006, the European Medicine Agency (EMA) requires an environmental risk assessment (ERA) for marketing authorisations of new medicinal products for human use. An ERA typically requires three experimental No Observed Effect Concentrations (NOECs) or EC10 values, i.e. for freshwater algae, invertebrates (typically daphnids), and fish. The problem is that many APIs authorized before 2006, often referred to as legacy APIs, lack sufficient ecotoxicity data. Generating these data is widely considered unfeasible due to ethical, technical, and financial constraints. In silico tools offer a promising alternative, by predicting ecotoxicity data in a way that saves time, reduces costs, and minimizes animal testing in line with the 3Rs principles (Replacement, Reduction, and Refinement of animal studies).
In this study, we identified existing in silico tools that can be used to predict chronic ecotoxicity endpoints in fish, Daphnia, and algae for 1,637 pharmaceuticals. In addition, we compiled an overview of chronic experimental data, including regulatory-compliant NOEC and EC10 for human pharmaceuticals. Predicted No-Effect Concentrations (PNECs) were calculated using both in silico and experimental ecotoxicity data. Predicted and empirical chronic ecotoxicity data, as well as PNECs, were compared in order to evaluate the performance of the selected models.
The preliminary results indicate that some tools have moderate predictive potential. However, the models typically fail to predict ecotoxicity values that fall at the extremes, particularly the very low ecotoxicity values. This is concerning in the ERA context because overlooking these effects may result in underestimation of environmental risks. To address this, we have started exploring whether the accuracy of predictions could improve within specific ranges of toxicokinetic and physicochemical parameters, such as logD or molecular weight. By exploring these factors, we want to gain a clearer understanding of the conditions in which the predictive models can be confidently used, particularly within the ERA context. In parallel, we aim to identify situations where the predictions may be less reliable and should be treated with caution.

4.14.P-Tu376 Utilising Optimised Machine Learning Soil and Sediment Sorption Models for Pharmaceutical Mobility Classification

***Nahum Ashfield**, Jun Li and Alistair Boxall, (1) University of York, United Kingdom*
Active pharmaceutical ingredients (API) have been widely detected in the environment, with concerns raised due to their potential for toxicity. API mobility within the environment has therefore become an increasingly important aspect of a chemicals hazard assessment, with an understanding of sorption behaviour in different solid environmental matrices a key part of this. Existing sorption modelling approaches for APIs are reliant on traditional regression-based methods for predicting sorption, which are limited in their ability to incorporate important descriptors, particularly those relevant to the ionisation of APIs in different environments. Machine learning (ML) has been presented as an avenue to improve prediction of complex sorption behaviours, with random forests showing good performance for soils and sediments. This work aimed to develop and evaluate new random forest sorption models for APIs, using freely available molecular descriptors to increase the accessibility of ML approaches for predicting sorption. New models were retrained using high quality soil and sediment linear sorption coefficients, with descriptors iteratively removed based on cross-validation to maintain model performance while reducing required data inputs. Validation of the optimised model against two external datasets from literature and industry demonstrated good performance, with 88.31% and 69.67% of predictions within a factor of 10 of experimental observations respectively. This optimised model was then used to assess the mobility of 1515 human and 146 veterinary APIs in use in Europe. Linear sorption coefficients for these APIs were predicted across 7 OECD-recommended soil types, normalised to organic carbon, and assessed against new EU chemical mobility thresholds. Based on model predictions 14.39% of human and 18.49% of veterinary APIs would be classified as very mobile in at least one of the 7 soils. Variability between soil predictions suggests that environmental pH is an important consideration for assessing ionisable pharmaceutical mobility. The results of this work highlight the advantages of ML as a tool for predicting API sorption behaviour across different environments, especially for legacy APIs where reliable empirical data is often limited, and serves as an example of how increasing accessibility to more advanced modelling approaches can provide a valuable way to prioritise APIs for further hazard assessment.

4.14.P-Tu377 Prioritising Pharmaceuticals by Comparing Plasma Concentrations Predicted by a Fish PBK Model with Human Therapeutic Plasma Concentrations

***Charlie Davey** and Ad Ragas, Radboud University, Netherlands*
Environmental risk assessment of pharmaceuticals faces challenges due to limited ecotoxicological data, compounded by the costs and ethical considerations of generating new data. Consequently, risk evaluations often rely on PNECs derived from incomplete datasets or QSAR predictions, underscoring the need for targeted prioritization of high-risk compounds for further testing.

4.14.P-Tu378 Quantification of the Potential Hazard and Risk of Pharmaceutical and Personal Care Products in Wastewater Treatment Plants, Combined with Hazard and Risk Screening Using In Silico Approaches

*Arianna Sgariboldi[1], Elena Post[2], Nicola Chirico[1], Alessandro Sangion[3], **Marco Evangelista**[1], Cristiana Morosini[1], Andrea Re[4], Vincenzo Torretta[1] and Ester Papa[1], (1) University of Insubria, Italy, (2)AIR CLEAN SRL, Italy, (3)ARC Arnot Research and Consulting Inc., Canada, (4)Xylem Water Solutions Italia Srl, Italy,*
Pharmaceuticals and personal care products (PPCPs) are contaminants of emerging concern. After wastewater discharge, PPCPs can reach various aquatic environments, including drinking water, where they may pose risks to human health and wildlife. Understanding the removal efficiency (RE) of these substances in wastewater treatment plants (WWTPs), and their subsequent environmental fate and behaviour, is a priority for the scientific and regulatory communities. This study examines the potential Persistence, Mobility, Bioaccumulation and Toxicity (PMT and PBT properties) of more than 200 PPCPs found in WWTPs worldwide and integrates experimental RE data, quantified in different WWTPs, with predictions from in silico models based on Quantitative Structure-Activity Relationships (QSARs). A dataset was compiled from 32 literature studies collecting information on WWTPs in Europe, Asia, Americas, Africa and Oceania. Experimental data included PPCPs concentration in water measured from influents and effluents of more than 70 WWTPs, RE values, and treatment types. Ultimately, data for 245 chemicals were selected for further analysis. The study included RE assessment, PBT and PMT

assessment using in silico predictions and the assessment of the potential risk in the aquatic environment. The molecular structures of the studied chemicals were represented using Simplified Molecular Input Line Entry System (SMILES) strings, which were used as input to apply freely available QSARs (e.g., OECD Toolbox, OPERA, EPI Suite, and QSAR-ME Profiler). After verifying the applicability domain of these models, predictions were compared with regulatory thresholds to identify hazardous chemicals and to screen PMT and PBT substances. Sixteen out of 245 chemicals were identified as potential PBT or PMT substances, six of which may pose a potential risk based on their concentration in WWTPs effluents reported in the literature. This study provides valuable insights to manage potentially hazardous chemicals and to mitigate potential risks by enhancing WWTPs efficiency or by substituting problematic substances with alternatives that are more easily removed and/or do not possess PMT and PBT characteristics. Combining literature data with in silico predictions supports the effective assessment of substances that are not adequately removed in WWTPs.

4.14.P-Tu379 PECsw Refinement Approaches in Medical Products with No Well-Defined Treatment Regimen

Giulia Baldone, *Giada De Angelis, Marco Domenico Rodda, Virginia Carlucci, Lara Brunasso Cattarello, Marta Lettieri, Enrico Gillio Tos and Antonio Conto, Chemsafe Srl, Italy*

The Environmental Risk Assessment (ERA), defined by the recently-revised guideline (2024), is the evaluation of the environmental impact of Human Medicinal Product (HMP), based on its release in the environment after its therapeutic use by the patients. The ERA is mandatory for all new Marketing Authorization (MA) applications for medicinal products. Nevertheless, its conclusions and implications currently do not impede the MA approval of the HMP. Altogether, this guideline describes a step-wise procedure based on the evaluation of the environmental exposure of the drug product, considering the predicted worst-case scenario use (dosage and posology). ERA phase I includes the calculation of the Predicted environmental concentration for surface water (PECSW) of the drug product, considering its maximum daily dose and standard values of wastewater/inhabitant/day and fraction of treated population. If the obtained PECSW is higher than 0.1 µg/L, this non-acceptable risk leads to Phase II triggering. In Phase II, PECSW may be refined by modifying the fraction of market penetration (FPEN), the proportion of the population being treated daily with a specific drug substance, based on actual prevalence data of the disease/s in the target area, and/or on the worst-case treatment regimen/s. However, challenging are the cases of sporadically used HMP, for example in the context of surgery interventions, which have a supposedly unpredictable frequency and involve an unforeseeable number of patients. Additionally, for a drug that treats symptomatology (rather than a pathology with a well-defined dose regimen), the duration of the treatment is often only vaguely suggested in the package leaflet and shall be often adjusted based on patients' real needs. These risk assessments have to be adjusted based on alternative approaches, like reasoning by absurdity or definition of a likely posology even for symptomatology-addressed drugs. Even if these approaches are in line with the scope of ERA, they are not taken into consideration in the reference guideline. It is unequivocal that the lack of specific guideline indications for these cases implies the need for clarification from health authorities in order to harmonize the approaches used for these peculiar assessments. Moreover, it is desirable that the Authorities responsible for the evaluation of the ERA assessments are willing to accept alternative approaches, adequately justified, in line with the scope of the ERA.

4.14.P-Tu380 Assessing the Value of Including Sediments in OECD 106 Studies for Pharmaceutical Environmental Risk Assessments

Joanne Elmoznino[1], Ed Schaefer[2] and ***Richard Murray-Smith[3]***, *(1)Pfizer Worldwide R&D, United States, (2)Eurofins-EAG Agrosciences, United States, (3)Regulatory Science Associates, United Kingdom*

Environmental risk assessment (ERA) of human medicines is typically focussed on the specific exposure pathways associated with down the drain chemicals, i.e. those that enter domestic wastewater treatment plants and subsequently enter the environment, either to surface waters or to the terrestrial environment via application of sewage sludge to land. The target environmental compartment for a drug ultimately depends on the partitioning behaviour between aqueous and solid media, firstly during wastewater treatment and then between surface water and sediment (for aqueous emissions) and/or between soil and porewater (for terrestrial emissions). The new European Medicines Agency (EMA) guideline on environmental risk assessment of human medicines requires an OECD 106 test for adsorption to sludge and soils. The role of sediment testing is less clear, although in both the previous (2006) and current (2024) EMA ERA Guideline, no preference is given to the use of soils or sediments in the OECD 106 sorption test. Because of this, many OECD 106 studies have included sediments, given that partitioning coefficients derived using sediments are arguably more relevant than those derived using soils for calculating potential sediment exposure

To explore the value or otherwise of including sediments in the OECD 106 study, historical adsorption data on pharmaceuticals have been reviewed for their utility under the new EMA ERA Guideline. Specifically, this work explores the importance of organic carbon vs other drivers of partitioning of pharmaceuticals, whether soil and sediment data can be pooled for the purpose of calculating geometric means, the implications for calculation of the predicted environmental concentration in sediment (PECsediment) and the determination of a meaningful predicted no effect concentration in sediment (PNECsediment), and if, or when, corrections for organic carbon content are appropriate. The hope is that this work will provide guidance on the use of adsorption data for soils and sediments, and address whether there is value in including sediments in future OECD 106 studies for pharmaceutical ERAs.

4.14.P-Tu382 Implementation Details Matter: Defining Micropollutants and their Hazardousness in the Context of the European Union's Revised Urban Wastewater Treatment Directive

***Sagar Thakali**, Stella Wang and Jennifer K. Saxe, Kenvue, United States*

As a part of the European Union s recently Revised Urban Wastewater Treatment Directive (UWWTD), the pharmaceuticals and cosmetics industry sectors will be responsible to pay extended producer responsibility (EPR) fees to fund quaternary treatment of micropollutants , where micropollutants are substances, including their breakdown products, that are usually present in the aquatic environment, urban wastewater or sludge and that can be considered hazardous, even at low concentrations, to the environment or human health on the basis of the relevant criteria set out under the regulation on classification, labelling and packaging (CLP Regulation). Small producers are exempt from EPR fees, and large producers are expected to pay based on the quantity and hazardousness of the micropollutants in products they place on the EU market. However, both the definition of a micropollutant and the basis for determining its hazardousness lack clarity, which is operationally critical to successfully implementing the EPR under the UWWTD.

We provide a review of scientific bases for defining micropollutants and determining their hazardousness. Considerations include, but are not limited to, the relevant health and environmental hazard categories under the CLP Regulation, biodegradability evaluation schemes, and data on treatment efficiency and the fate of substances in wastewater treatment plants. We then explore potential operational definitions and approaches, which may be considered in the context of the UWWTD.

The outcomes and recommendations from this study are intended to support identifying a scientifically sound process for regulatory implementation of the UWWTD by the EU member states. Hence, we also discuss the practical considerations and implications of the possible definitions of micropollutants and of the approaches to determine their hazardousness, with the goal of supporting a fair, harmonized and transparent application of the polluter pays principle and ultimately influencing innovation to identify and transition to the use of more benign substitutes for the micropollutants in question wherever possible.

4.14.P-Tu383 Using a Consistent Framework for Literature Reviews Improves Confidence in Environmental Risk Assessment of Pharmaceuticals

***Sagar Thakali**[1], Jennifer K. Saxe[1], Rebecca Jayne Brown[2], Dean Leverett[2], Sharon Swales[3] and Irene Bramke[4], (1) Kenvue, United States, (2)wca, United Kingdom, (3)Smithers, Shawbury, Shrewsbury, United Kingdom, (4)AstraZeneca, United Kingdom*

There is growing interest and openness to incorporate new approach methods (NAMs) into regulatory environmental risk assessments (ERAs) to minimize traditional reliance on animal test methods and utilize existing data on chemical properties and environmental fate. The European Medical Agency s (EMA) 2024 Guideline on ERA of Human Medicinal Products allows the use of literature studies as alternatives to requisite empirical studies and recommends the use of approaches to minimize the need for new animal testing. However, there is limited guidance on how to conduct the literature data search, potentially leading to multiple Applicants conducting ERAs for the same Active Pharmaceutical Ingredient (API) using inconsistent data, especially if not all relevant data is identified or assessed for relevance and reliability. Furthermore, the available data will be presented in different formats, making it difficult for the regulators to check gaps and inconsistencies in the datasets.

A framework, presented separately, has been developed to identify critical studies/data and to assess their relevance and reliability in a robust and consistent manner, so they can replace and/or supplement empirical studies required by the regulations. Several case study examples will be presented for the application of the proposed framework for literature search and review strategy, including for a new API antibody drug conjugate and a generic API with multiple published studies. The case study examples will highlight the decision points, where using an explicit framework for selecting and evaluating studies to include in the ERA supports consistency and reliability.

The initial case study examples demonstrate how a consistent approach to literature review and data searches can not only increase the confidence in the regulatory ERA s reliance on existing data, but can also avoid unnecessary and redundant testing, particularly animal testing. The findings and lessons learned will contribute to establishing transparent use of existing relevant literature studies and to promoting the 3Rs principles, in accordance with the stated intention of the 2024 EMA Guideline on ERA.

4.14.P-Tu384 A Standard Approach for Literature Data Review Required Under Revised EU Pharmaceutical Environmental Risk Assessment Guidance

*Olivia Lin Tran[1], **Rebecca Jayne Brown**[1], Rebecca Marks[1], Lucy Kennelly[1], Rachel Moreby[2] and Irene Bramke[2], (1)wca Environment Ltd, United Kingdom, (2)AstraZeneca, United Kingdom*

The European Medicines Agency (EMA) recently updated guidelines for the environmental risk assessment (ERA) of medicinal products for human use (EMA 2024). This guideline now requires the applicant to provide a complete literature review (including details on how the literature search was performed, i.e. identity of the search engine and terms used for the search), with the stated purpose to identify endpoints of significance to the ERA and to prevent repetition of (animal) studies . However, no further instructions are provided on how to conduct the literature search. In this poster, we present an approach for the literature and data search required for regulatory pharmaceutical ERAs. Case-studies on application of this approach are presented separately. The approach is based on established principles and strategies to promote and maintain consistency among regulators and applicants.

For both new and existing active pharmaceutical ingredients (APIs), a bibliographic search is performed to identify data from published literature. Searches can be conducted on one or more platforms (e.g., Web of Science, Scopus, PubMed, US EPA ECOTOX), using a tiered process to balance the scope of the search and amount of information to assess. The first tier is based on the substance identifiers only. A second tier utilises search strings specific to information types (i.e. physchem, fate, ecotox, bioaccumulation etc.), if refinement is required to reduce the number of results to screen. A set of criteria is proposed to determine potential relevance to endpoints of significance to regulatory ERA.

For existing APIs, authoritative databases are searched for any proprietary data and existing approaches to ERA, e.g., assessment reports and summaries from the EMA, US FDA, Fass, and ECHA CHEM databases/websites.

Any potentially relevant data identified this way is assessed in detail to determine the ultimate relevance and reliability for inclusion in ERAs, following Criteria for Reporting and Evaluating ecotoxicity Data (CRED, Moermond et al. 2016) for ecotoxicity studies or equivalent criteria (e.g., OECD test guidelines) for other study types (e.g., physico-chemical and environmental fate data).

We propose this approach as a standard for literature searches for APIs requiring a regulatory ERA, which benefits both, the applicant and the reviewer, by ensuring that relevant and reliable literature data is used to support regulatory ERAs.

4.14.P-Tu385 Applicability of the European Commission's framework on safe and sustainable by design to the pharmaceutical sector

*Neele Puhlmann[1], **Elisabetta Abbate**[2], Klaus Kummerer[1], Agnes G. Oomen[3], Ad Ragas[4] and Caroline Moermond[5], (1) Leuphana University Luneburg, Germany, (2) Radboud University Nijmegen & European Commission, Joint Research Centre, Italy, (3)National Institute for Public Health and the Environment (RIVM), Netherlands, (4) Radboud University Nijmegen, Netherlands, (5) University of Amsterdam, Netherlands*

The chemical sector contributes significantly to anthropogenic impacts on planetary health. Thus, there is a need for a green transformation. The same holds for the pharmaceutical sector. To assist with this transformation, European Commission s Joint Research Centre (JRC) developed a framework on Safe and Sustainable by Design (SSbD) for chemicals and materials (SSbD framework). The general structure of the SSbD framework leaves room for sector-specific priorities and practices. This study explores the applicability of the SSbD framework to the pharmaceutical sector; more specifically to the development, production and use of Human Medicinal Products (HMPs). We show that the stage-gate process in R&D of HMPs fits very well with the design assessment
process of the SSbD framework, making the framework conceptually applicable to pharmaceutical R&D.

Future efforts should focus on the development of i) methods to predict environmental safety and sustainability based on the limited data available during R&D, ii) a pragmatic procedure integrating SSbD into HMPs innovation, and iii) a weighing system considering also environmental safety and sustainability parameters alongside patient safety and medical efficacy. Although the assessment phase of the JRC s SSbD framework has specifically been developed for innovation purposes, we propose an expansion of its scope to pharmaceutical products already on the market. The reason is its applicability by healthcare actors to guide safer and more sustainable choices regarding the use of marketed HMPs. We call this approach Safe and Sustainable by Comparison (SSbC) and show that the assessment principles of the SSbD framework can be applied to SSbC.

4.14.P-Tu386 Pan-European Risk of in-use Pharmaceuticals to the Environment

***Sarah Roberts**, David Spurgeon, Stephen Lofts, Catherine Barnett and Sam Harrison, UK Centre for Ecology and Hydrology (UKCEH), United Kingdom*

Pharmaceutical pollution is of rising concern due to the increasing demand and use of human and veterinary medicines and their subsequent release into the environment via excretion, improper disposal and manufacturing. There is growing scientific literature on the occurrence and fate of active pharmaceutical ingredients (APIs) in aquatic and terrestrial environments, and vast amounts of existing monitoring data available across Europe, particularly for surface waters. Using available data, our work aims to assess pollution risk of APIs to aquatic and, where possible, to terrestrial ecosystems. As part of the EU HORIZON ETERNAL project which studies aspects of sustainable API manufacture, use and disposal, our work designs a ranking approach to identify current in-use APIs that present the greatest risk to aquatic and terrestrial environments. A database has been constructed which collates available API exposure monitoring datasets across environmental compartments (i.e., surface waters, groundwaters, sediments and soils) from numerous data portals (i.e., Environment Agency water quality monitoring, UK Water Industry Research Chemical Investigation Program, NAIADES, NORMAN EXPODAT, German Environment Agency UBA pharmaceutical database) and scientific literature. In total, our database contains concentrations for > 600 pharmaceutical compounds (parent and transformation products) from monitoring sites across Europe (> 30 countries), which we have used to explore the magnitude and frequency of occurrence of API exposure. Some of the most commonly measured APIs in the environment include antibiotics, analgesic and estrogenic medications, and some of the highest exposure concentrations collated from the data sources are those for antibiotics and veterinary insecticide substances. To catalogue the relative toxicity of APIs detected in the environment, the hazardous concentration for 50% of species (HC50) values from Species Sensitivity Distributions (SSDs) were collated from the National Institute for Public Health and the Environment SSD database for 12,386 chemicals. Our community-based risk assessment approach uses SSD-derived HC50 values as these give a lower uncertainty and higher robustness in comparison to traditionally used HC5 values. Environmental exposure concentrations and SSD-derived HC50 values for ~ 400 API parent and transformation products are combined to provide a risk ranking of current in-use pharmaceuticals to ecosystems.

Disclaimer/Disclosure: This project has received funding from the European Union s Horizon Europe Framework Programme (HORIZON) under grant agreement No 101057668. The work of UK-based Associated Partners has been funded by UK Research and Innovation (UKRI) under the UK government s Horizon Europe funding guarantee [grant number 10040111].

4.14.P-Tu387 Exploring the Trade-Off Between Environmental Impact and Therapeutic Effect. A cross sectional study assessing preferences among Swedish general practitioners

***Johanna Villen**[1], Johanna Laux[2], Bjorn Wettermark[1], Sofia Kalvemark Sporrong[1], Marmar Nekoro[1] and Helle Haakonsen[3], (1)Uppsala University, Sweden, (2)Leipzig University, Germany, (3)University of Gothenburg, Sweden*

Introduction/Aim: Prescribing and use of pharmaceuticals in primary care belong to the most important factors contributing to healthcare s environmental impact. Consequently, prescribers are major stakeholders that can reduce the environmental footprint of pharmaceuticals. There is limited research on general practitioners (GPs) attitudes towards environmentally responsible prescribing practices. This study explores Swedish GPs preparedness to incorporate environmental considerations into treatment decisions. Methods: A questionnaire to assess environmental considerations in prescribing was developed and distributed to 1,233 Swedish GPs and physicians under training between September 2023, and June 2024. The questionnaire included three simulated patient cases, focusing on pharmaceuticals used for contraception, pain management, and blood pressure reduction, to assess the trade-off between environmental impact and therapeutic effect of the treatment. Additional questions about the respondent s attitudes coupled to pharmaceuticals and environmental issues were included. Responses were analysed

using descriptive and inferential statistics.
Results: Out of 1,233 GPs invited, 272 responded (response rate: 22%). More than half (58%) were women, 63% were born in 1980 or later, and 29% were physicians under training. A majority (88%) indicated that environmental and climate considerations were very or fairly important. Many of the respondents were willing to prescribe a less effective pharmaceutical if it was environmentally preferable, 77% for pain management and blood pressure reduction and 50% for contraception. Environmental impact was ranked as the least important factor compared to treatment cost, regional treatment guidelines, dosage intervals, and user-friendliness in terms of factors influencing their prescribing decisions. However, 24% of respondents stated that they often or always considered environmental impact when prescribing pharmaceuticals.
Conclusions: Swedish GPs are willing to consider environmental impact when making prescribing decisions for certain conditions, but other factors are valued higher in their decision-making.

4.14.P-Tu388 Unnecessary Fish Bioaccumulation Testing of Pharmaceuticals Driven by Use of Ion-Corrected LogDow in PBT Assessment

Samuel K Maynard[1], *Rachel Moreby*[1], *Jim McCabe*[1] *and Irene Bramke*[2], *(1) AstraZeneca, United Kingdom, (2)AstraZeneca, Netherlands*

The recently revised EMA guideline on environmental risk assessment of human pharmaceuticals provides guidance specific to ionizable compounds for the assessment of fish bioaccumulation potential as part of the PBT assessment. Two physical chemical properties inform this:
1) Dissociation constant (pKa) value(s) experimentally determined according to OECD TG 112,
2) LogDow data, experimentally determined according to OECD TG 107 or 123, "… determined as a function of pH covering an environmentally relevant pH-range (at least 3 pH values ranging from pH 5 to 9), e.g. by measuring the pH-lipophilicity profile (log D as function of pH)".

In addition to this, an "ion-corrected logDow for the neutral molecule" is to be determined mathematically according to equation $Kow=Dow \cdot (1+10(pH-pKa))$. PBT/vPvB assessment is triggered if any extrapolated, ion-corrected Dow value(s) meet or exceed criteria (logKow > 4.5), irrespective of the pH at which the molecule is predicted to present as the neutral species. PBT screening initially starts with assessment of the bioaccumulation criteria by an experimental fish BCF test. The guidance further clarifies"…the BCF test [OECD305] should be conducted at a stable pH consistent with the most bioaccumulative form of the test chemical (usually the non-dissociated form or the form with the most neutral molecule species)."

However, fish testing triggered by a corrected Log Dow manifest at a pH < 6 or > 8.5 would not be possible to conduct due to the restrictions of the OECD 305 test guideline. Some extension beyond this recommended pH range may be possible but great care should be taken to account for fish welfare and the physiologically tolerable range of species tested when interpreting results.

PBT/vPvB assessment is often described as an assessment of the "intrinsic" properties of a molecule, intended to account for the potential for harm irrespective of exposure. However in the EMA guidance there is no clarification on the environmental relevance of the pKa value used to determine the ion-corrected LogDow; therefore even at very extreme pH's a fish BCF study could be triggered which has no environmental relevance.

Here we will present a scientific approach to consider the environmental relevance of a PBT assessment, demonstrating both theoretically and using relevant examples, that the experimentally determined LogDow values are sufficient for the assessment of bioaccumulation, and avoid unnecessary fish testing.

4.14.P-Tu389 Concept for Implementation of an Environmental Information, Classification and Dissemination System in Germany ("Arzneimittelindex Umwelt")

Clemens Woitaske-Proske[1], *Arne Hein*[2], *Gerd Maack*[2], *Rodrigo Vidaurre*[3], *Yannick Heni*[3] *and Christian Peifer*[1], *(1)Christian-Albrechts-University of Kiel, Germany, (2)German Environment Agency (UBA), Germany, (3)Ecologic Institute, Germany*

Residues from pharmaceuticals enter the environment via various entry pathways and are measured in some areas at concentrations exceeding threshold concentrations. Effects on organisms can be detected and with the increasing use of pharmaceuticals in an ageing society, this problem will become even more acute in the future. There are several initiatives along the pharmaceutical life cycle that try to tackle this problem. One promising way of lowering the impact of pharmaceuticals on the environment is

encouraging physicians and pharmacists to prescribe and dispense medicines in an environmentally responsible manner. The aim of this study was to develop a concept for an environmental information, classification and mediation system suitable for the German healthcare system. Furthermore, this concept should be developed on the basis of lessons learnt from these pioneer countries and in close coordination with relevant stakeholder groups to reach high effectiveness and acceptance. To achieve this goal, case studies from Sweden, Finland and Scotland were combined with a literature review of peer-reviewed literature, policy briefs and grey literature, supplemented by interviews with relevant local stakeholders. Based on this information a concept suitable for the German healthcare system was developed and discussed in stakeholder workshops
The concept of this information and classification system is feasible in Germany and is able to lower the entry and impact of pharmaceuticals into the environment (PiE) at the point of decision making. Over and above that, several other stakeholder such as health insurances can use this information to make environmentally sound decisions. This study is relevant, as it describes a concrete concept ready to be implemented in a time were PiE are of rising concern. Additionally, in contrast to end-of-pipe approaches it displays a possible solution approach that can be implemented easier, faster and more cost effective. Furthermore, examples from other countries show, that such a system is effective in driving decisions and is therefore an effective way of environmental decision making in drug prescribing and dispensing.

4.14.P-Tu390 Revision of the Guideline on the Environmental Risk Assessment of Medicinal Products for Human Use
***Annika Buck**[1], Rhys Whomsley[1], Cristiana Cannata[2], Corinne de Vries[1] and Eadaoin Griffin[3], (1)European Medicines Agency, Netherlands, (2)Environmental Science, Radboud University Nijmegen, Nijmegen, Netherlands, (3)Health Products Regulatory Authority, Ireland*
The European Medicines Agency (EMA) has published a revised version of the guideline (GL) on the environmental risk assessment (ERA) of medicinal products for human use. First published in 2006, the GL describes the assessment of the potential environmental risks and hazards of human medicinal products (HMP) arising from their use. It provides guidance for applicants and regulators on how the ERA should be performed. After releasing a draft revision of the GL for public consultation in 2018, extensive feedback was received after the six-month consultation period. The ERA drafting group who undertook the initial draft revision worked through these comments between 2019 and 2024 and made additional amendments to the published draft to address this feedback. This drafting group comprises technical and regulatory experts recruited from national competent authorities (NCAs) and national environmental authorities and works under the remit of the Nonclinical Working Party of the CHMP. Responding to the feedback received during the public consultation, the revised GL aims to deliver the guidance in a more detailed, comprehensive, and visually appealing way. Regulatory and technical aspects addressed in the final revision were issues regarding clarification of scope concerning excipients, access to existing ERA, especially with regard to generics, the need for a deeper explanation of secondary poisoning (SP) assessment, and the persistence, bioaccumulation and toxicity (PBT/vPvB) assessment. Furthermore, adjustments were made in Phase II Tier B risk assessment regarding the refinement options of the predicted environmental concentration of the surface water compartment (PECsw) and concerning entry pathways of HMP into the groundwater compartment. Finally, changes were implemented regarding the proposed labelling for PBT/vPvB substances and a manual has been included as an annex which describes in detail the Simple Treat model used in the Phase II Tier B risk assessment to refine the PECsw.
The revised GL provides a more comprehensive approach to the ERA both for applicants and assessors, taking into account scientific developments and changes in relevant guidance documents under other legislative frameworks.

4.14.P-Tu391 How Doctors and Pharmacists Can Avoid Harmful Medicines – A Simple Concept to Flag Environmentally Friendly Substances
***Arne Hein**[1], Clemens Woitaske-Proske[2], Rodrigo Vidaurre[3] and Gerd Maack[1], (1)German Environment Agency (UBA), Germany, (2)Institute of Pharmacy, Kiel Univerity, Germany, (3)Ecologic Institute, Germany*
Pharmaceuticals are released into the environment through multiple pathways and can be found in significant concentrations, already exceeding threshold concentrations in some areas. There are numerous ongoing initiatives along the pharmaceutical lifecycle trying to reduce the input of pharmaceuticals into the environment. A high impact in this respect can be achieved at the beginning of the life cycle, as well as by reducing the number of prescriptions/dispensing of medicines or optimising them towards eco-

prescriptions/dispensing. An environmental information and classification system for pharmaceuticals, such as in Sweden and Finland, is a tool that can help choose more environmentally friendly pharmaceuticals. In a feasibility study the implementation of such a pharmaceutical index environment (Arzneimittelindex Umwelt) in Germany was investigated. In addition, to the pillars information and dissemination systems a concept for the classification of active substances in pharmaceuticals was requested, which enables doctors and pharmacists to distinguish between environmentally harmful pharmaceuticals from those available to them.
Several existing classification concepts are based on different approaches or combinations of approaches: effects on non-target organisms, fate in the environment (persistency), consumption, occurrence in the environment or carbon footprints. After consultation with potential users in the healthcare system, a simple and understandable system such as the embrytox.de labelling is proposed, which should be based on independently verified results. For the information system the use of public results from European environmental risk assessments according to the technical guideline of the European Medicines Agency is suggested. The same criteria could also be used to classify all marketed active substances. In that way the classification approach will cover the environmental risks and hazards identified in study reports used in the application process, as well as the chemical nature of the substance.
We will present the concept of a simple, clear and concise classification system by flagging substances that are less harmful or unlikely to pose a risk to the environment but also harmful substances. The poster will include an impact assessment of the proposed classification scheme for all active substances marketed in Germany and will also show practical application examples for doctors and pharmacists.

4.14.P-Tu392 Monograph System for Active Substances of Pharmaceuticals

***Jan Pridohl**, Daniela Gildemeister and Arne Hein, German Environment Agency (UBA), Germany*

Since-the mid-2000s, Environmental Risk Assessments (ERAs) for active substances of human and veterinary medicinal products (HMP/VMP) have been required according to the respective EU Directives (2001/82 and 2001/83).
For a few years now, the data derived from those ERAs have been summarised in (European) Public Assessment Reports ((E)PAR) after the authorisation procedure of the respective medicinal products. These documents are only partially publicly available and usually lack several environmental information e.g. data already investigated through other authorisation procedures. In some cases, information is not published due to the authorisation holder's confidentiality rights. Therefore, it is hardly possible to collect all relevant data for an active substance based on (E)PARs, only. Also, updates of (E)PARs are currently not legally required. Thus, harmonised evaluations of HMP and VMP, respectively, containing the same active substance are rather impeded.
Generating an active substance based monograph system would be a promising solution and would also be in accordance with the international and EU environmental information law (environmental information according to Art. 2 (3) (b) of the Aarhus Convention), as well as the EU Commission s proposal for a revised Pharma legislation (COM [2023] 192 final).
Such a monograph system should contain not only fate and effect data, but also predicted environmental concentrations (PEC) and necessary risk mitigation measures (RMM). When all information are then summarised in one document, it will be easier to update the monograph with the latest data. Different levels of access to the data can be provided for the relevant stakeholders.
The poster will present our proposal for a monograph structure of ERA data. Verified as well as publicly available data for a well known active substance of a pharmaceutical over the counter product have been summarised. The poster includes endpoints (e.g. PEC, effect and fate data), a proposal for a study summary and a list of implemented RMM.
A substance monograph should be frequently updated by the (Co) Rapporteur/Reference Member State. This monograph approach also supports the data sharing and data provision recommendation of the new ERA-Guideline for HMP (EMEA/CHMP/SWP/4447/00 Rev. 1- Corr.) and easily harmonises the EU-wide environmental risk assessment of pharmaceuticals.

4.14.P-Tu393 Availability, Need and Use of Environmental Data – State of the Art and Prospects for the Future

***Daniela Gildemeister**, Arne Hein, Jan Pridohl, Louis-Marvin Sander and Kim Teppe, German Environment Agency (UBA), Germany*

"Environmental data are a prerequisite for identifying active pharmaceutical substances for which appropriate risk mitigation measures may be necessary. Formally, environmental data should be published according to the Aarhus Convention, but pharmaceutical data from authorisation procedures lack this transparency.
In this presentation we want to show what is already available and what could be available in the future

with respect to the proposal of the European Commission (EUCom) for a revised Pharmaceuticals Legislation. In reference to the Aarhus convention there may be possibilities to publish more data than it is currently the case.
Therefore, a review is done of current legislation and recent interpretations by a German administrative court (Cologne) about the confidentiality of environmental data. The new GL was analysed for publication issues and the legal restrictions within this GL were identified. Published data available in (European) Public Assessment Reports (EPAR) were compared with available data from authorisation processes to identify publication gaps. The available data were compared to the number of active substances on the market in Germany and the number of monitored substances to identify the availability gap.
In the proposal of the EU Com for a revised Pharmaceuticals Legislation the main changes foreseen to improve the data availability situation are

4.14.P-Tu394 Out of sight – The Insufficiency of Terrestrial Veterinary Pharmaceutical Regulatory Limits in Early Risk Assessment

Louis-Marvin Sander[1], Ute Kuhnen[1], Thomas Backhaus[2] and ***Gerd Maack****[1], (1)German Environment Agency (UBA), Germany, (2)Institute for Environmental Research (IFER), RWTH Aachen University, Germany*

The VICH GL 6 outlines a tiered assessment scheme that is mandatory for all active substances (AS) used in veterinary medicines before they enter the market. As the first step, the predicted environmental concentration of the AS in question is compared to a so-called action limit of 100 ?g/kg for soil. If this action limit is exceeded, an extended environmental risk assessment is required. This limit is currently based on data that were recorded between 1973 and 1997 in the USA. Since then, new active ingredients with higher efficacy (and, therefore, potential environmental impacts at lower concentrations) have been developed and put on the market. This consequently elevates the probability of environmental and organismic impact, which in turn affects biodiversity and, ultimately, the natural functioning of ecosystems.
A critical evaluation of the action limit is therefore necessary. Does it still serve its purpose as a precautionary decision criterion on whether an experimental Phase II risk assessment must be conducted? To assess the protectiveness of the soil action limit of 100 µg/kg, we evaluated 82 tests (34 plant and 48 earthworm tests) for 18 parasiticides, 28 antibiotic and 5 other AS, using data from European Medicines Agencies Public Assessment Reports, supplemented by internal data of the German Environment Agency. We included parasiticides in the data evaluation, although the action limit does not apply here, as their environmental hazard is determined by their toxicity to insects. Tests between model predictions reveal no difference between models with and without parasiticides (with parasiticides $n = 51$, without parasiticides $n = 33$). For each AS, we included the lowest available NOEC/EC10 and fitted a sigmoidal non-linear least squares model in the range of [0,1].
18±5 % of the NOECs/EC10 values are below 100 µg/kg soil. This reduces to 17±6 % if only non-parasiticides are included in the data analysis. A total of 11 substances are below or equal to the action limit, 7 antibiotics and 4 parasiticides. In order to ensure that the action limit covers approximately 95 % of AS currently on the market, a reduction from 100 to 5 µg/kg would be necessary. The analysis shows that the current action limit is insufficient to protect organisms and ecosystems. In future revisions of the guideline, it will be necessary to adapt the action limit to current scientific standards.

Disclaimer/Disclosure: Realised as part of a project by the German Environment Agency (Research Identification Number: 3723 67 4020).

4.14.P-Tu395 Toxicity of the Veterinary Pharmaceuticals Pyrantel Pamoate and Ractopamine in Zebrafish Embryos (Danio rerio)

Luis Terrazas Salgado*[1], Justin Dubiel[1], Lauren Zink[2], Ilakkiya Thirugnanasambandam[3], Tabitha Gangur-Powell[3], Tara Vucurevich[4], Tara Shelton[3], Jonathan Karl Challis[3] and Steve Wiseman[1], (1)University of Lethbridge, Canada, (2)University of British Columbia, Canada, (3)Lethbridge Research and Development Centre, Agriculture and Agri-Food Canada, Canada, (4)Lethbridge Research and Development Centre, Agriculture and Agri-Food Canada, Israel*

Widespread use of veterinary pharmaceuticals to treat livestock has resulted in their entry into aquatic environments. Unlike human drugs, which pass through wastewater treatment plants before being discharged into the environment, veterinary drugs are usually excreted through urine and feces and released directly into the environment, potentially reaching rivers, ponds, etc. The presence of veterinary drugs in water bodies is a current issue of concern, as their excessive use is a potential risk to aquatic organisms. Two widely used veterinary drugs are pyrantel pamoate and ractopamine. Pyrantel pamoate is an antiparasitic used to treat infections by intestinal worms such as pinworms, roundworms, and hookworms; it acts as a depolarizing neuromuscular blocking agent, causing a sudden contraction, followed by paralysis, of the worms. Ractopamine is a synthetic ?-adrenergic agonist (?-adrenergic receptors modulate metabolic functions in fish such as oxygen uptake, heart rate, vascular resistance, and the binding affinity between hemoglobin and oxygen), used as a feed additive to increase feed efficiency, accelerating growth and increasing weight gain in animals. Using zebrafish as a model teleost, the goal of this study was to characterize the toxicity of pyrantel and ractopamine using an extended zebrafish embryo toxicity test OECD 236). Embryos were microinjected with either DMSO or with pyrantel or ractopamine at 0.4, 2.0, 10, and 50 ng/g of egg and reared until 15 days post-fertilization, during which time they were assessed for mortality, malformations, heart rate, and locomotor disorders. There was a dose-dependent increase in mortality (EC = 36,982 ng/g egg). There was a small but statistically significant dose-dependent increase in heart rate between control and pyrantel-treated (2, 10, and 50 mg/mL) embryos at 48 h, with control embryos averaging 160 bpm, whereas pyrantel-treated embryos averaged 162 (0.4 mg/mL), 164 (10 mg/mL), and 166 (2 and 50 mg/mL) bpm at 48 hpf. This is expected to impact the larvae's locomotor activity (behavior) directly and may be affected and neurodevelopmental disorders may be identified in the drugs. The effects of ractopamine are currently being determined. Overall, results to date suggest that embryonic exposure to pyrantel might have posed a threat to fish and contributed to a better understanding of potential environmental hazards posed by some veterinary drugs in fish.

4.14.P-Tu396 Using Zebrafish G Protein-Coupled Receptors to Obtain a Better Appreciation of the Impact of Pharmaceuticals in Wastewater to Fish

Han Zhang[1]*, Monika D. Jurgens*[2]*, Andrew C. Johnson*[2]*, Jingwen Chen*[1] *and Masaru Ihara*[3]*, (1)Dalian University of Technology, China (Mainland), (2)UK Centre for Ecology and Hydrology, (3)Kochi University*

Pharmaceutical discharge to the environment is of concern due to its potential adverse effects on aquatic species. It is estimated that around 40% of pharmaceuticals target G protein-coupled receptors (GPCRs). The in vitro transforming growth factor-? (TGF?) shedding assay has been applied to measure the antagonistic activities of pharmaceuticals against human GPCRs. However, their ability to stimulate fish GPCRs remains unclear. Here, the antagonistic activities of 30 pharmaceuticals against zebrafish dopamine (zD2a, and zD2c), adrenergic family member (z?1), and histamine (zH1 and zH3) receptors were measured by the TGF? shedding assay. The study found interspecies difference in binding affinities between human and zebrafish: pharmaceuticals more strongly inhibited the zebrafish zD2c and zH1 receptors than human D2 (hD2) and hH1 receptors, while zebrafish zD2a and z?1 were less inhibited than human hD2 and h?1 receptors. The interspecies difference in binding affinity for hydroxyzine (an antihistamine medication) was explained by molecular docking. Pharmaceutical potency against zebrafish GPCRs and predicted effluent concentrations were used to predict equivalent quantities (EQs), and then these EQs were used to prioritize pharmaceuticals of concern in wastewater in England and Japan. This study highlights the use of the TGF? shedding assay adopting zebrafish GPCRs to better understand the ecological effects of pharmaceuticals on fish.

4.14.P-Tu397 Ecological Risk Assessment of Sulfa Drugs: A Case Study Using Component Based Approach for Chemical Mixtures

Fujiko Ozawa[1]*, Takayuki Nakajima*[2]*, Atsushi Yoshizawa*[1]*, Saori Machi*[1]*, Hiroshi Yamamoto*[1] *and Koichi Ohno*[1]*, (1)Health and Environmental Risk Division, National Institute for Environmental Studies (NIES), Japan, (2)Global Environmental Forum, Japan*

Sulfa drugs are a large group of substances widely used as human and veterinary medicines. They are very similar in structure and have antibacterial activity through the same mode of action. In addition, they are harmful to aquatic organisms and thus, an ecological risk assessment has been carried out. In Japan, environmental risk assessments (ERAs) for regulatory purposes focus primarily on individual chemicals. However, substances with the same mode of action are expected to have combined effects when present in the environment at the same time. It is therefore necessary to assess the combined effects of the sulfa drugs rather than the individual chemicals.

The aim of this study is to verify and further investigate relative potency factor (RPF) approach for higher tier ecological combined risk assessment that we have been exploring so far, using simple estimated environmental discharge values in addition to actual measured concentrations in the environment, with a focus on the use of sulfa drugs in livestock and aquaculture.

Literature searches were carried out to collect environmental concentration data using databases such as J Dream III. Some of the literature we obtained reported that water concentrations of some sulfa drugs and trimethoprim (TMP) were relatively high in some rivers near livestock farms. The combination of sulfamethoxazole (SMX) and TMP has been reported to have a synergistic antibacterial effect by inhibiting successive steps in the bacterial folate synthesis pathway. Based on the above, the assessment group in this study was refined to seven sulfa drugs used in veterinary medicine and feed additives and TMP. A regression equation derived from trend analysis between parameters related to the mode of action and toxicity values was used to calculate the RPF of the sulfa drugs included in the assessment group. Although the synergistic effect of TMP on the effects of sulfa drugs is not considered in this study, the inclusion of synergistic effects is a common issue in the combined effect assessment of substances acting on target molecules. We also report on a case study of ecological combined risk assessment, where the concentration in rivers was estimated from the amount of antibacterial substances used in the livestock and fisheries industries, and it was used as the exposure concentration.

4.14.P-Tu398 Determination of the Effect of the Presence of Coccidiostats and Nutritional Metals on the Degradation of Tiamulin in Poultry Litter

Bethany Adams[1]*, Laura Carter*[1]*, Chris Sinclair*[2]*, Philip Rooney*[3]*, Paul Kay*[1] *and Edward Haynes*[3]*, (1)University of Leeds, United Kingdom, (2)Bayer S.A., São Paulo, Brazil, (3)Fera Science Ltd, United Kingdom*

The potential impact of feed additives on the degradation of veterinary medicines in poultry litter is not well understood. Currently guidance provided by the European Medicines Agency and the European Food Safety Authority states that only one substance should be assessed at a time in a simulated manure degradation experiment. By focusing on a single substance, the current assessment of veterinary medicines and feed additives does not consider the impact of co-contaminants on the degradation of these compounds in manure. Manure is a sink for many contaminants in the environment, therefore it is critical to ensure that the risk assessment processes are environmentally realistic. A series of experiments were designed to explore the impact of co-contaminants frequently detected in manure, namely coccidiostats (both ionophores and synthetic) and nutritional metals on the degradation of the antibiotic tiamulin. Litter was collected from a working poultry farm and physico-chemical properties were characterised before use in series of manure degradation experiments. The litter was dosed with tiamulin at a concentration of 10 µg/g and different combinations of coccidiostats and nutritional metals including, salinomycin, diclazuril, copper and zinc. Spiked manure samples were incubated under controlled conditions to evaluate the impact on the fate of tiamulin during its degradation. Methods employed were in line with the harmonised experimental guidance published by the European Medicines agency in 2011 and OECD320 (where appropriate). This study is ongoing with preliminary results showing that the presence of synthetic coccidiostats may slow the degradation of tiamulin in poultry litter. The results from this study will allow us to better understand the factors that drive the variability in the degradation in veterinary medicines in different poultry litters from different farms and understand whether these co-contamination leads to an underestimation of exposure during environmental risk assessment.

4.14.P-Tu399 Veterinary Antimicrobials in EU: Goals, Use and Ecotoxicity

Renata Dagiliute, Diana Miškelytė, Gintare Sujetoviene, Austra Diksaityte, Irena Januskaitiene, Giedre Kaciene and ***Jurate Zaltauskaite****, Vytautas Magnus University, Lithuania*

Antimicrobial use contributes not only to antimicrobial resistance, but poses environmental effects like ecotoxicity, altered species interaction and in general ecosystem health. Therefore, attention to the antibiotics use both for humans and food producing animals increases in scientific and political agenda. So far antimicrobial use for veterinary needs comprises the biggest share of all antimicrobials. Consequently, much tighter targets for reducing the use of veterinary antibiotics compared to the use for humans are set on EU level. Hence, paper aims to analyse antimicrobial use for veterinary antimicrobials in EU countries over 2011-2022 and estimate distance to target for 25 EU member states. In addition, potential ecotoxicity related to the veterinary antibiotics use is also estimated. Data of the European Surveillance of Veterinary Antimicrobial Consumption on overall sales of veterinary antimicrobial medicinal products and according to antimicrobial class (tetracycline, sulphonamides, fluoroquinolones, 3rd- and 4th-generation cephalosporins, other quinolones and polymyxins) is used for this purpose. Results show that over analysed period overall use of veterinary antibiotics has decreased, with the least drop of fluoroquinolones. However, further decrease is needed to reach EU target and proposed global levels for veterinary antimicrobials use. Despite decrease of overall and per PCU antimicrobials use, some countries are still using two or more times extra veterinary antimicrobials compared to the set goal for EU on average. Hence, in addition to the human health threats, those countries contribute relatively more to the environmental degradation, too. Therefore, such countries should rethink current policies or their implementation to reach more sustainable use of veterinary antibiotics and to implement one health approach.

4.14.P-Tu400 Ecological Risk Assessment of Human Pharmaceuticals Detected in Japan: Seasonal and Temporal Variations

Hiroshi Yamamoto[1]*, Yoshikazu Ninomiya*[2]*, Haruna Watanabe*[1]*, Takahiro Yamagishi*[1]*, Norihiro Kobayashi*[3] *and Takashi Yamada*[3]*, (1) National Institute for Environmental Studies (NIES), Japan, (2)The University of Tokyo, Japan, (3)National Institute of Health Sciences, Japan*

Guidance for environmental risk assessment (ERA) of new human pharmaceuticals were published in 2016 by Japan Ministry of Health, Labour and Welfare but the risk assessment became voluntary-base and the comprehensive ecological risk of pharmaceuticals have not been conducted in Japan. Last year, we presented the results of short-term (sub-)chronic aquatic toxicity tests using three species, zebrafish (Danio rerio) short-term test with embryo and sac-fry stage (OECD TG212), Ceriodaphnia dubia reproduction test (USEPA s WET test method), and green alga (Raphidocelis subcapitata) growth inhibition test (OECD TG201) for nearly 30 out of approximately 100 pharmaceuticals detected in rivers (95 percentile values were used for the risk assessment) all over Japan. This year, we additionally conducted these three tests for 5 pharmaceuticals without chronic data to determine No Effect Concentration (NOEC). Since the total of nearly 700 water samples were collected for comprehensive chemical analysis of nearly 100 pharmaceuticals using an LC-MS-MS to determine the spatial and temporal distribution of measured environmental concentrations (MECs) in the period of 2019-2021 all over Japan. So, this year, we conducted ecological risk assessment to determine the distribution of risk quotient (MEC/NOEC) in Japan. We found that antibiotics such as macrolides are relatively at high risk with MEC/NOEC ratio above 0.1 for alga in some sites while the maximum ratio was in the range of 0.01-0.1 for daphnid. The risk ratio for fish was found to be below 0.001 for most of the water samples and least risk for the selected 100 pharmaceuticals but we need to keep in mind that the testing was the short-term testing at embryo and sac-fry stages and endocrine disrupting effects on reproduction were not included.

4.15.P Sunscreens and Personal Care Products in the Environment: New Data and Approaches to Evaluate Environmental Risks and Possible Solutions

4.15.P-Mo384 Monitoring and Effects of UV-Filters on Diverse Algal Species

Lalita Chomphen[1]*,* ***Alejandra Bouzas Monroy***[1]*, Harald Streicher*[2]*, Jun Li*[1]*, Ieuan Roberts*[1]*, Lorraine Maltby*[3] *and Alistair Boxall*[1]*, (1)University of York, United Kingdom, (2)Beiersdorf AG, Germany, (3)School of Biosciences, University of Sheffield, United Kingdom*

The widespread use of UV filters in personal care products (PCPs) has raised concerns about their potential environmental impact, particularly on aquatic ecosystems. This study investigated the presence and ecotoxicity of four UV filters homosalate, octocrylene, benzophenone-3, and bemotrizinol in UK rivers and their effects on 12 algal species. A monitoring campaign sampling water from 19 locations across 10 rivers in Yorkshire, UK, over eight months was also carried out. The ecotoxicity study employed a newly developed method using a well plate reader to assess algal growth inhibition. Twelve algal species, including green algae, blue-green algae, and diatoms, were exposed to seven concentrations of each UV filter for 72 hours. Through GC-MS, the samples were analysed for the various UV filters. The concentrations detected ranged from ng/L to µg/L with octocrylene exhibiting the highest concentration, peaking at 807 ng/L in the River Aire, while benzophenone-3 reached 430 ng/L in the River Wharfe. EC50s values were determined, revealing significant interspecies variability in sensitivity. The diatom Aulacoseira granulata was the most sensitive species, with EC50 values of 0.027 mg/L, 0.0061 mg/L, and 0.295 mg/L for homosalate, octocrylene, and benzophenone-3, respectively. In contrast, green algae exhibited higher EC50 values, often exceeding the water solubility of homosalate and octocrylene.This study highlights the presence of UV filters in riverine systems and their potential ecological risks. The findings suggest that A. granulata, not currently included in OECD guidelines, may be a critical indicator species for future ecotoxicity assessments. These results emphasize the need for comprehensive research into the cumulative effects of UV filters in aquatic environments.

4.15.P-Mo385 Occurrence and Distribution of UV Filters in Sediments from the Baltic Sea

Harshada Sakpal[1]*, Luca Boke*[2]*, Marion Kanwischer*[3]*, Detlef Schulz-Bull*[3] *and Kathrin Fisch*[1]*, (1)Julius Kuhn-Institut, Germany, (2)Germany, (3)Leibniz Institute for Baltic Sea Research Warnemunde (IOW), Germany*

The occurrence of organic ultraviolet filters (UV filters) is of increasing concern due to their ability to be endocrine disrupters and bioaccumulative in the environment. Globally, the use of organic UV filters as active ingredients in sunscreens, personal care products and industrial materials is growing exponentially. The Baltic Sea is a popular holiday and leisure region exposed to high anthropogenic pollution by persistent, toxic, and bioaccumulative pollutants. One group of these pollutants is UV filters, which enter the Baltic Sea mainly through river inflows, wastewater treatment plants, and recreational activities. Previous studies have highlighted the presence of UV filters in the coastal areas of the Baltic Sea. The goal of the project is to investigate the spatial distribution of UV filters in open seas and coastal waters, simultaneously also their distribution in sediments in the Baltic Sea. In the current study, sediment cores were collected from four sampling stations in the German Baltic Sea. The sediment cores were sliced every two centimeters and examined individually for UV filters. The advantage of this approach is that it allowed us to analyze undisturbed sediments and study the distribution of UV filters at various sediment depths. The extraction of UV filters from the sediment samples was carried out utilizing the QuEChERS method. The QuEChERS method was significantly optimized using suitable extraction agents with subsequent purification steps by solid phase extraction (SPE) to yield maximum recovery. The final extracts were further measured with LC-MS/MS. Our Initial findings detected UV filters, octocrylene, benzophenone-4, UV-P and PBSA in surface water samples. This study provides more insight if UV filters with high log Kow values, such as octocrylene, avobenzone, homosalate, and padimate-O, accumulate in the sediment due to their high lipophilicity and persistence. This research provides a more comprehensive understanding of the distribution of UV filters at different sediment depths in the Baltic Sea, which helps us examine the role of sediments as sinks for UV filters.

4.15.P-Mo386 Organic UV Filters Detected in Coastal Waters and in the Coral Acropora cervicornis on the Florida Reef Tract

Dorothy-Ellen Abigail Renegar[1]*, Andrew Heyes*[2]*, Michael Gonsior*[2]*, Ellen Regina Englert Skelton*[1] *and Carys Louise Mitchelmore*[2]*, (1) Nova Southeastern University, United States, (2)University of Maryland Center for Environmental Science, Chesapeake Biological Laboratory, United States*

Organic UV filters have been detected in both seawater and in marine biota, highlighting the potential for uptake and environmental risk from exposure. However, a limited number of studies have measured UV filters in seawater near coral reefs, and even fewer have examined UV filters in coral tissues. This study was designed to examine correlations between UV filter concentration in the water column and parallel UV filter concentrations in tissues of the endangered Atlantic staghorn coral Acropora cervicornis.

The concentrations of 12 organic UV filters were assessed in matched seawater (shallow surface and at coral depth) and coral tissue samples from one offshore nursery in Fort Lauderdale, Florida, and two offshore nurseries in the Florida Keys. The onshore nursery at The Florida Aquarium (FLAQ) served as an ex-situ control. No UV filters were detected in either seawater or coral tissues at the ex-situ onshore control site, and some UV filters were either below the detection limit or detected in very low (ng/L) concentrations in seawater at the offshore nurseries. Six of the 12 UV filters were detected in shallow and coral-depth water at the offshore nurseries located near Fort Lauderdale and near Tavernier in the Florida Keys, and three of the 12 organic UV filters were detected in shallow and coral-depth water near Carysfort Reef in the Florida Keys. Octocrylene, avobenzone, and homosalate were detected at all three offshore nursery sites. In general, avobenzone, oxybenzone, and padimate were detected predominately in the dissolved fraction, and homosalate, octinoxate, and octisalate were detected only in the particulate fraction. Octocrylene was found in both fractions, with the highest concentrations at the northernmost (Fort Lauderdale) and southernmost (Tavernier) nurseries.

Overall, organic UV filter concentrations in the water column were consistent with expected levels of anthropogenic contamination at each site and temporal changes in rainfall patterns. These data inform the range of environmentally relevant concentrations for future risk assessments on the potential impacts of UV filters, and provide critical support for regulatory policies and management decisions concerning UV filters in Florida coastal waters. As UV filter concentrations are highly variable in space (location, water depth, distance from source) and time, further assessments are required to identify sources and the temporal range of concentrations near coral reefs.

4.15.P-Mo387 Dissipation Kinetics of Ultraviolet Filters in Mesocosms and Occurrence in a Freshwater Beach on the Canadian Prairies

Jose Luis Rodriguez Gil[1]*,* ***Alistair Kendrick Brown***[2]*, Mark L. Hanson*[2] *and Annemieke Farenhorst*[2]*, (1)IISD-Experimental Lakes Area, Canada, (2)University of Manitoba, Canada*

UV Filters (UVFs) are found in a wide range of cosmetics, personal care products, and commercial stabilizers. UVFs are known to be toxic to aquatic organisms in both freshwater and marine environments, and are also known to be strong endocrine disruptors, thereby impacting human and environmental health.

It is important to quantify the exposure to total UVFs in a recreational environment and to calculate aqueous dissipation kinetics and half-lives to elucidate environmental persistence and fate. We quantified four of the most popular and common UVFs approved for Canadian sunscreen and cosmetic usage in freshwater mesocosms in Winnipeg, Canada over summer/fall 2024. Data collected was used to backstop what we saw in a freshwater beach study conducted in June to September 2022, and to guide future full-scale experiments. The four UVFs were octisalate, octocrylene, oxybenzone, and sulisobenzone. The mesocosms were divided into two treatments in triplicates: sediment and macrophytes, and with water-only; and they were dosed with a mixture of the UVF suite at 50 µg L-1 each. They were chosen to be representative of the range of hydrophobicity (LogKOW) of UVFs at 5.77, 7.35, 3.79, and 0.88, respectively. Analyses were done using direct injection, isotope dilution, ultra-high performance liquid chromatography-tandem mass spectrometry, and polarity switching; and aqueous dissipation half-lives were calculated. For sulisobenzone, the mesocosms with sediment and water-only treatments, half-lives of 17 and 30 days were calculated, respectively. Oxybenzone had lesser initial concentrations most likely due to some sorption to plants, sediments, or the tanks themselves, and in the sediment and water-only treatments half-lives of 2.9 and 3.6 days were calculated, respectively. Fluctuations in concentrations of UVFs are most likely due to user application choices in addition to sorption to sediments, photolysis, and hydrolysis which is what was seen in the freshwater beach study. Although oxybenzone was seen to be the most labile in the kinetics study, it was the most abundant UVF at the beach over the summer, which speaks to consumer usage. The impact of these results can guide water quality guidelines to protect ecosystem health, and to industry to drive new eco-friendly sunscreen formulations.

4.15.P-Mo388 Environmental Fate of UV Filters: Comparing Lake Monitoring Data with Controlled Exposure in Artificial Ponds

*Alexandra Kroll[1], Simone Tinguely[2], Benjamin Gygax[2] and **Armin K. Zenker**[2], (1)Ecotox Centre, Eawag, Switzerland, (2)University of Applied Sciences Northwestern Switzerland (FHNW), School of Life Sciences, Institute of Ecopreneurship, Switzerland*

In the EU 47 substances are currently authorised for the use as UV-filters in cosmetic products. Additionally, the inorganic and several of the organic substances listed in the EU Cosmetics Regulation are also registered or authorised for other uses (agrochemicals, biocides, coatings, inks, stabilisers, cleaning agents, air care) according to the REACH registration information and may thus enter the environment via additional pathways. Accordingly, these substances can enter the aquatic environment directly through bathing or via WWTP effluents.

The fate of the UV filters was investigated in five different lakes and four artificial ponds in Switzerland. After sampling, the organic UV filters were preconcentrated by Oasis HLB solid phase extraction and afterwards determined on a high-performance liquid chromatography coupled to triple quadrupole mass spectrometer. The studied UV filters were ingredients currently used in sunscreens which were as follows 2-Ethylhexylsalicylate, 2-Phenylbenzimidazole-5-sulphonic acid (PMDSA), Avobenzone (AB), Octinoxate, Octocrylene, Oxybenzone, Ethylhexyl triazone, 4-Methylbenzylidene camphor, Disodiumphenyldibenzimidazoltetrasulfonat, Isoamyl 4-Methoxycinnamate, and Homosalate.

Octocrylene occurred in almost all sampled lakes in concentrations of over 1 ug/L in summer. Concentrations of up to 5 ug/L were determined in the smaller bathing waters. High concentrations were found in the surface water and less in the water column. AB was determined in small lakes in concentrations of up to 3 ug/L and in at least 10 times higher concentrations in surface water than in the water column. However, the hydrophilic PMDSA was sometimes found in concentrations of up to 3.7 ug/L in the surface water, twice as high as in the water column. This suggests that the formulation of the sunscreen products is also influencing the behaviour of the UV filters in the water body.

4.15.P-Mo389 Freshwater Safety Assessment of UV-Filters Using a Spatially Resolved Aquatic Exposure Model for Down-the-Drain Substances in Europe

*Susan A Csiszar[1], Kyle Roush[1], Chiara Maria Vitale[2], Nikita Litvinov[1], Raghu Vamshi[3], Ryan Heisler[4], **Kathleen McDonough**[1] and Iain Davies[5], (1)Procter & Gamble, United States, (2)Procter & Gamble, Belgium, (3)Waterborne Environmental (contributing affilitation), Corteva Agriscience, United States, (4)American Cleaning Institute (contributing affiliation), International Collaboration on Cosmetics Safety, United States, (5)Personal Care Products Council, United States*

A key aspect of environmental safety of consumer use down-the-drain (d-t-d) ingredients is environmental exposure in receiving waters. This is the reason for legislation such as the European Urban Wastewater Treatment Directive that was implemented to set standards for wastewater treatment to help reduce environmental loading of d-t-d ingredients to better protect human and environmental health. A global framework to estimate d-t-d substance concentrations in river catchments across the globe that leverages large spatial datasets on population, wastewater treatment (WWT) infrastructure, per capita water use, river connectivity, and river flow has been developed and demonstrated for several countries to better assess exposure potential. This framework was built on the well-established iSTREEM® model for the United States, and provides estimated river concentration distributions based on spatial variability of these parameters, as well as chemical-specific properties such as WWT removal and in-stream decay. Recently, this framework has been expanded to include Europe by leveraging official European Union data on several WWT parameters, including geographic locations of wastewater treatment plants (WWTP), and demonstrated good agreement with reported values for Europe. The model is publicly available and free for use. We present the application of this model to two key UV-filters used in personal care products (PCPCs), Oxybenzone and Octinoxate, and compare to monitored concentrations. We also demonstrate the model application to freshwater safety assessment by comparison to predicted no-effect concentrations (PNECs). Modelled concentration distributions were found to be in good agreement with monitoring data, while still being conservative. Additionally, 50th, 75th, and 90th percentile modeled and monitored concentrations were found to be substantially lower than PNECs, respectively, indicating favourable margins of safety even at the high-end of the concentration distribution. The use of spatially resolved exposure models are key tools for understanding concentration distributions across modelled regions and for use in prospective safety assessments of substances that are released down-the-drain. They can also be valuable to more accurately prioritize ingredients that could be targeted for refined removal via wastewater treatment.

4.15.P-Mo390 Developing Reliable Standard Analytical Protocols for the Detection of Multiple Organic UV Filters in Environmental Matrices

*Stefanie Landeweer, Michael Gonsior, Andrew Heyes and **Carys Louise Mitchelmore**, (1)UMCES, CBL, United States*

Ultraviolet (UV) filters are used in a wide range of products, including sunscreens, and have been detected in water, sediment and biota. Orders of magnitude different concentrations have been observed in environmentally matrices and in toxicity thresholds reported. Differences reported may in part be due to the varying analytical methods used. Furthermore, adequate and accurate assessments of the concentration of the UV filter under study in toxicity testing is critical and underpins the reliability and defensibility of the toxicity thresholds derived from the study. We have observed contamination from laboratory plastics, carry-over of UV filters if re-used containers were not adequately solvent cleaned/baked, losses during analytical sampling, storage, extraction and analysis at various points depending on the UV filter under study and the materials used. In a previous oxybenzone study we found losses due to binding to glass sampling containers, retainment in the solid-phase cartridge, which would have resulted in underestimations of toxicity if not accounted for. We summarize our lessons learnt and recommend appropriate extraction procedures and analytical assessments for working with UV filters from field-collected environmental matrices and toxicity test samples with the goal to develop standard methods for UV filters.

An LCMS-based analytical method was developed to detect and quantify twelve organic UV-filter compounds, with limits of detection ranging from 0.02 to 9 ng/L. In order to test the effectiveness of the extraction method and the utility of the recovery standards, spiked solutions of all analytes at two different concentrations were prepared in deionized water and artificial seawater (n=6). These samples were prepared, extracted, and analyzed using the same method as environmental samples. In addition, standard solutions in artificial sea water were prepared and kept in the dark at room temperature, 4 and -20°C before being analyzed in order to test the analytes stability. The use of isotopically-labeled recovery standards added before solid-phase extraction increased both recovery and reproducability. All compounds tested had a recovery of 80% or greater after recovery standard correction. This indicates that the extraction and analytical methods are well-suited for the analysis of UV filters in seawater samples. Additionally, all UV filters were shown to be stable over short periods at all tested temperatures.

4.15.P-Mo391 Temporal and Spatial Variations of UV Filters at a Popular Recreational Beach in Florida, USA

***Carys Louise Mitchelmore**[1], Andrew Heyes[1], Michael Gonsior[1], Dorothy-Ellen Abigail Renegar[2], Iain Davies[3] and Stefanie Landeweer[1], (1)UMCES, CBL, United States, (2)NSU, United States, (3)PCPC, United States*

Ultraviolet filters are a diverse group of compounds with a wide range of commercial applications, including as ingredients in sunscreens. To understand the temporal variation in concentrations of UV filters seawater samples were collected over a diurnal period in March and May 2024 at a popular recreational beach in Fort Lauderdale, Florida, USA which has coral reefs located offshore. Three composite samples (n=10 discrete samples) were collected along two 100m transect locations that were different distances from the shore (T1; nearshore in the bathing zone and T2 ~50m from the shoreline). Samples were immediately processed by filtering (GFF) and solid phase extraction to prepare the dissolved fractions with the GFF filters frozen and later extracted via hexane extraction to prepare the particulate fractions. During processing recovery standard spikes were added. All extracts were analyzed quantitatively for 12 organic UV filters using LC-MS.

Eight analytes, oxybenzone (BP-3), octocrylene (OC), homosalate, octisalate, avobenzone, octinoxate, and, OD-PABA were measured in all samples, with May levels consistently higher. UV filter concentrations were higher at T1 and reduced significantly at T2, with at least a 60% decrease. All UV filters followed similar temporal trends with peaks in the mid afternoon (2-4 pm) reflective of the number of recreational users. Partitioning of the UV filters between the dissolved and particulate fractions matched their physio-chemical properties. BP-3 concentrations were nearly all in the dissolved phase and only a small fraction was present in the fraction retained on the GFF-filters i.e., particulate phase. Alternatively higher concentrations of OC were observed in the particulate versus dissolved phases reflective of its lower solubility and higher logKow.

Overall, these results highlight that aquatic organisms in popular recreational areas may encounter UV filters that are highly variable over a 24-hour period rather than a steady environmental concentration, emphasizing the importance of sampling for UV filters at times of both high and low recreational activity. Concentrations rapidly decline out of the bathing zone highlighting that both location and time is important in risk assessments. Furthermore, to understand total concentrations and exposure routes and minimize analytical error, it is important to conduct assessment of partitioning by filtering samples.

4.15.P-Mo392 Monitoring Campaign for Organic UV Absorbents from Recreational Sunscreens on Okinawa Beaches Using Passive Sampling with Alabaster-Cement Composite Disks, Grab Sampling, and a Questionnaire Survey

Yutaka Kameda *and Emiko Fujita, Chiba Institute of Technology, Japan*

Organic UV absorbents found in cosmetics, particularly in sunscreens, have been reported to pose potential ecological risks to aquatic organisms, including coral bleaching. In recent years, scientists worldwide have monitored concentrations of these compounds in beaches and coastal areas to assess exposure levels for ecological risk assessment. However, UV absorbent concentrations vary widely based on factors such as the number of swimmers, tides, sunscreen usage, and other environmental conditions. Therefore, determining both peak concentrations and time-weighted average concentrations (TWAc) is essential to evaluate acute and chronic risks. In this monitoring campaign, we investigated daily concentration trends of seven UV absorbents in beach water through grab sampling. We also used DGT® passive sampling with alabaster-cement composite disks to estimate TWAc in the water. Additionally, sunscreen types and quantities used by beachgoers were recorded through a questionnaire survey. The seven UV absorbents analyzed included benzophenone-3, EHMC, 2-phenyl-5-benzimidazole sulfonic acid, octyl dimethyl PABA, octocrylene, bemotrizinol, and ethylhexyl triazone, which were quantified using liquid chromatography-tandem mass spectrometry. Sampling was conducted at three sites: one within the beach area and two offshore. Approximately 200 tourists participated in the questionnaire survey. Concentrations of some UV absorbents fluctuated in response to the number of beachgoers throughout the day. However, benzophenone-3, which is no longer widely used in Japanese cosmetics, was not detected via grab sampling at any time. This monitoring campaign will continue over several years, providing valuable data to support ecological risk assessments and develop predictive models for UV absorbent contamination and its associated risks.

4.15.P-Mo393 Organic UV Filters in Irish Sediments and Biosolids

Martin Sharkey[1]*, Yulong Ma*[2]*, Stuart Harrad*[2]*, Mark Healy*[1]*, William A. Stubbings*[2] *and Marie Coggins*[1]*, (1)University of Galway, Ireland, (2)University of Birmingham, United Kingdom*

The assessment and monitoring of ultraviolet filters (UVFs) in environmental matrices is of vital importance. Ongoing monitoring of UVFs restricted under the Cosmetics Products Regulation (CPR) is needed to ensure levels in the environment remains or falls below thresholds for high ecotoxicological risk. Investigation into emerging UVFs of concern, such as those listed under the Water Framework

Directive s (WFD) Watch List , is necessary where insufficient data is available to determine the safe levels of use. Meanwhile, determining the potential sources of environmental contamination with UVFs is needed to identify areas where preventative measures to reduce said contamination might be necessary. To that end, we report herein the results of a nationwide campaign which investigated levels of five prominent UVFs (4-MBC, BP-3, EHMC, HMS, and OC) in inland and transitional sediments across Ireland, along with sewage sludge/biosolids emanating from wastewater treatment plants.
Mean concentrations in biosolids were as follows: OC (666 ng/g); HMS (453 ng/g); 4-MBC (13.9 ng/g); EHMC (12.7 ng/g); and BP-3 (1.28 ng/g). Concentrations in Irish biosolids are lower than those determined in similar studies worldwide, though this is the first available data on HMS in biosolids. Mean concentrations in sediments were as follows: OC (3.66 ng/g); HMS (2.35 ng/g); 4-MBC (1.87 ng/g); BP-3 (0.19 ng/g); and EHMC (0.04 ng/g), showing a similar profile to concentrations detected in sediments. Though detected at comparatively moderate concentrations, 4-MBC was detected by far the most frequently: in 93 % of sediments samples. Ninety-fifth percentile risk quotients (RQ95) were determined for each UVF in sediment based on predicted no-effect concentrations as promulgated by the NORMAN Network. Each of 4-MBC, EHMC, and HMS were found to be of a moderate level of risk (0.40, 0.13, and 0.11 respectively) based on their measured concentrations. Significantly higher concentrations of UVFs were detected directly adjacent to or immediately downstream (< 0.5 km) wastewater emission points ($p < 0.01$).
Continued monitoring of HMS and 4-MBC in the short term is recommended to determine the efficacy of regulations limiting their use, and further data is needed for OC, EHMC, and BP-3 to provide a more thorough risk assessment as pertains to the WFD. The elevated levels of HMS in biosolids found herein highlights the need for further assessment internationally.

Disclaimer/Disclosure: This project is funded under the EPA Research Programme 2021-2030 (2021-HE-1056) and co-funded by the Department of Agriculture, Food and the Marine. 4.15.P-Mo394 The Ecotoxicological Effects of Two Contrasting UV Filters Derived from Sunscreens (oxybenzone & nano titanium dioxide), on the Temperate Marine Microalgae Species Isochrysis Galbana.

Anneliese Ananya Hodge[1], *Awadhesh Jha*[2], *Frances Hopkins*[3] *and Mahasweta Saha*[3], *(1)Plymouth Marine Laboratory & University of Plymouth, United Kingdom, (2)University of Plymouth, United Kingdom, (3)Plymouth Marine Laboratory, United Kingdom*

Ultraviolet (UV) filters are organic and inorganic compounds added to sunscreens to protect against the sun s UVA and UVB rays. UV filters have been detected in both freshwater and marine matrices around the world, but despite the ubiquity of these compounds, little research has focused on the molecular, cellular and individual level effects on temperate marine organisms and primary producers.

Adopting a multidisciplinary approach, this research aims to understand the ecotoxicological effects of two widely used and contrasting UV filters, oxybenzone and nano-titanium dioxide on the temperate marine microalgae species Isochrysis galbana. Methods used include the use of flow cytometry to assess for cellular density and growth, chlorophyll fluorescence analysis, as well as oxidative damage and antioxidant response microplate assays. Additionally, biogeochemical techniques have been adopted to analyse the effect of UV filters on sulphur compound production using gas chromatography.

To date, our results indicate that environmentally relevant concentrations of oxybenzone reported in the literature (1-100 ?g/L-1) can have adverse effects on Isochrysis galbana, with a significant decline in cell density within 24 hours of exposure at very low concentrations (1-10 ?g/L-1) and mortality within 48 hours of exposure to 30-100 ?g/L-1. Chlorophyll-a content within the algae significantly declined in a dose-response manner over 96 hours, but there was no indication of oxidative stress. For nTiO2, there was no effect to the algae at 1 ?g/L-1, but a decline in cell density and growth was observed between 10-100 ?g/L-1 and 5-100 mg/L-1. Chlorophyll-a content was also affected from 10 ?g/L-1, which continued in a dose-response manner. Lipid peroxidation was observed at both 50 and 100 mg/L of nTiO2, and at these concentrations, 100% mortality took place within 72 hours.

This ongoing research aims to better understand the effects of both organic and inorganic UV filters on temperate marine organisms. Current regulations on the use of UV filters in personal care products in both the UK and the EU are lax in comparison to other global nations. This research aims to provide evidence that can help policymakers to understand the true potential of UV filters derived from sunscreens on temperate marine organisms, and to make informed decisions about which compounds should be better regulated within sunscreens and personal care products.

4.15.P-Mo395 The Hidden Impact of Human Presence: Organic UV Filter Levels on an Oceanic Island Coastal Waters, Northeast Atlantic

Eva Iñiguez Santamaría[1]*, Rodrigo Pires da Silva*[2]*, Sarah Montesdeoca-Esponda*[3]*, Filipe Alves*[2]*, Goncalo Barros*[4]*, Nereida Cordeiro*[5]*, Manfred Kaufmann*[6] *and Ana Dinis*[2]*, (1)Marine and Environmental Sciences Centre (MARE); Aquatic Research Network (ARNET); Madeira Agency for the Development of Research Technology and Innovation (ARDITI); Interdisciplinary Center of Marine and Environmental Research (CIIMAR), University of Por, Portugal, (2) Marine and Environmental Sciences Centre (MARE); Aquatic Research Network (ARNET); Madeira Agency for the Development of Research Technology and Innovation (ARDITI); Portugal, (3)Instituto Universitario de Estudios Ambientales y Recursos Naturales (i-UNAT), Universidad de Las Palmas de Gran Canaria, Spain, (4)Observatorio Oceanico da Madeira - ARDITI, Portugal, (5)LB3, Faculty of Exact Science and Engineering, University of Madeira, Portugal, (6)Faculty of Life Science, University of Madeira, Portugal*

Subtropical oceanic islands have become increasingly popular tourist destinations. Official recommendations to protect the skin from harmful sun rays have led to a rise in the use of sunscreens containing UV filters, which are directly introduced into coastal waters during recreational activities. Characterized by high photostability and lipophilicity, organic UV filters are persistent compounds that can remain in the ecosystem for extended periods.

This study aims to evaluate the impact of human activities on coastal ecosystems, focusing on quantitatively assessing organic UV filters throughout the marine food web. By analyzing species across different trophic levels, including macro-algae, zooplankton, invertebrates, and fishes. We determined how these contaminants move through the ecosystem and asses their concentration in Madeira Island, Portugal.

Samples were collected from three sites: Funchal, the capital (densely populated and touristic, high anthropogenic pressure), Lombada dos Marinheiros in the west of the island (remote area, low anthropogenic pressure), and the Desertas Islands (uninhabited and Marine Protected Area). UV filters were extracted using Microwave-Assisted Extraction and analysed via UHPLC-MS/MS.

Results showed that organic UV filters' highest concentrations and detection frequency were from samples collected in Funchal, while the lowest levels were found in the Desertas Islands. Zooplankton and algae exhibited the highest concentrations, reaching up to 1028.6 ng/g and 292.67 ng/g respectively. Among fish, cowfish (Sarpa salpa) showed higher concentrations (up to 472.22 ng/g of total UV filter concentration), likely linked to herbivorous diet, while invertebrates (sea urchin Arbacia lixula and sea cucumber Holoturia sanctori) mostly had levels under the limit of detection, potentially due to low environmental exposure or dilution by ocean dynamics. Octocrylene and homosalate were the most common compounds, reflecting their prevalence in European sunscreen products.

These findings highlight the ecological impact of human activities on coastal waters, stressing the need for monitoring emerging contaminants to protect marine health and fish consumer's safety. The study underscores the urgency for standardized assessments of environmental levels and toxicological thresholds to inform effective mitigation strategies which could include European regulation to create and market more environmentally friendly cosmetics.

Disclaimer/Disclosure: This research was supported by Gran PRT/BD/153506/2021 financed by The Portuguese Foundation for Science and Technology (FCT), and funds from MARE-Madeira and Universidad Las Palmas de Gran Canaria under the MIT Portugal Program.

4.15.P-Mo396 UV Filters Modify Light Colour Preference in the Zooplanktonic Species Daphnia magma

Juliette Bedrossiantz, Silvia Diaz-Cruz and ***Carlos Barata****, (1)IDAEA-CSIC, Spain*

UV filters are ubiquitous in the environment, having been detected globally in wastewater, freshwater and marine environments. While the use of UV filters in sunscreens and cosmetics are important for human health, their risk and impact to aquatic or terrestrial organisms is not well studied. Most ecotoxicological studies conducted so far with UV filters in aquatic invertebrates and algae used conventional endpoints such as mortality, growth and reproduction.There is less information on the effects of UV filters on zooplankton species. Many freshwater and marine zooplankton species show anti-predatory behavioural responses to light to avoid visual predators like fish. Antipredator behavioural responses include scape responses to light such as increase motility under light and diel vertical migration characterized by swimming towards deep and dark waters during daylight and towards surface waters during night to feed on alga. It is also known that many of those species used particular light wavelengths to trigger their migratory movements and other ones to search for food. One of the properties of UV screens is to filter certain light wavelengths. Here we present data showing that two well known UV filters, octocrylene and benzophenone-3 are able to modify the light wave length colour preference of the zooplanktonic and ecotoxicological model species Daphnia magna. To do that we build a new behavioural device able to monitor vertical and horizontal locomotion tracks of organisms across varying light wave lengths and intensities. Our results indicate that sublethal concentrations of octocrylene were able to reduce the swimming speed of exposed organisms and increased their photophobia to the tested light wavelengths. Furthermore the blue colour preference of exposed organisms also changed: octocrylene at low concentrations decreased D. magna preference for blue light, whereas at higher concentrations together with benzophenone-3 increased the preference for the blue relative to the red, white and green lights. The above-mentioned light colour preferences changes may have important ecological effects as the blue colour light is the wave length that penetrates more into the water column, is the preferred one for several zooplanktonic species and is the one that trigger the most the diel vertical migration. Acknowledgement - The authors thank the Spanish Government for the funding of the projects PID2023-148502OB-C2,PID2023-151815OB-I0.

4.15.P-Mo397 A New Approach to Assessing the Impact of Active Ingredients and Cosmetic Formulations on Coral Reefs

***Julien Bertin**[1], Vincent Bourgeteau[2] and Antoine Combot[2], (1)Ecotoxicology, SGS France, Saint Etienne du Rouvray, France, (2)EcoSeaStems, France*

Threatened first and foremost by rising sea temperatures, pollution and ocean acidification, coral reefs are also undermined by human activities, which are accompanied by the introduction of cosmetic products into the marine environment.

The proposed protocol gathers coral cuttings from 12 to 50 coral species exposed to the product to be tested. After a 24-hour exposure period, the short-term impact is evaluated from observations such as polyp closure, loss of color, and signs of necrosis. The corals are then transferred to quarantine aquariums for a two-week recovery period to assess medium-term effects. Throughout the testing period, marine biologists closely monitor the corals health and physio-chemical parameters in the aquariums.

At first, a sunscreen formulation containing widely used organic filters was tested according to this protocol. After 20 hours of exposure, and the 14-day recovery period, 36% of the species displayed necrosis.

Replication of this test on more than 20 cosmetic formulae coupled with the analysis of the water in contact with the formulae resulted in the identification of key formulation criteria to characterize ecotoxic criteria.

This first cartography will also help us to select the most relevant species to establish EC50 and toxicity thresholds, in order to improve our understanding of species-specific sensitivities.

These results underscore the importance of comprehensive ecotoxicological testing of cosmetic products on a diverse range of coral species to accurately assess their potential impact on coral reef health.

4.15.P-Mo398 Advances in Standardized Ecotoxicological Testing with Scleractinian Coral Larvae

***Laura Jana Fiegel**[1], David Brefeld[1], Valentina Di Mauro[1], Matthias Y. Kellermann[1], Samuel Nietzer[1], Mareen Moeller[1], Laura Lutjens[2], Sascha Pawlowski[3], Mechtild Petersen-Thiery[2] and Peter Schupp[4], (1) Carl von Ossietzky University of Oldenburg, Germany, (2)BASF SE, Germany, (3)GBP/RA, BASF SE, Germany, (4)Carl von Ossietzky University of Oldenburg; the University of Oldenburg (HIFMB), Oldenburg, Germany*

Coral reefs face substantial ecosystem shifts under increasing anthropogenic threats. Personal care products, for example, are expected to contain compounds (e.g. UV filters) that may harm corals. To assess the effects of these compounds on corals, it is necessary to develop standardized test guidelines. Current methods mainly focus on the adult life stage of corals, however, juvenile corals and particularly coral larvae might be more sensitive to various stressors (e.g. substances, environmental samples). To close their lifecycle, coral larvae need to settle on the reef and develop into adult coral colonies. If the settlement process is inhibited, the swimming larvae will eventually die, which could have far-reaching consequences for the propagation of corals resulting in little or no recruitment of juvenile corals and large-scale reef degradation in the long term.

This study refines the experimental design for a standardized toxicity test on coral larvae, evaluating the larval endpoints settlement and mortality, which was first introduced by Miller and colleagues in 2022. To improve variabilities of recovery rates, the experiments here were conducted in glass containers, resulting in nearly 100% recovery rates of both, benzophenone-3 (BP-3) and the positive control Diuron (DCMU), which would the allow to refer the determined EC50 or LC50 values to the nominal test concentrations. Preliminary results already indicated that the effect of BP-3 on the ability of larvae to settle may be the most sensitive endpoint for corals. However, implementing a settlement endpoint is challenging, as the application of biological settlement cues (i.e., crustose coralline algae and microbial biofilms) tend to (1) trigger variable settlement responses in different coral species and (2) the additional biological components in the test vessels may interact with the test substances. The recently described chemical settlement cue cycloprodigiosin reduces the variability in the settlement endpoint and prevents unintended interactions between the biological cue and the target substance resulting again in increased recovery rates. The latter improvements in the experimental design will enable further testing of the effects on coral larvae and develop holistic coral bioassays in a standardized way.

Disclaimer/Disclosure: The authors declare that this study received funding from BASF SE (Ludwigshafen, Germany) through the grant Toxicity tests with corals and coral reef communities, grant number 5551622859. Opinions expressed in the paper are those of the authors; the funder had no role in the study design, data collection, analysis or interpretation of the study findings.

4.15.P-Mo399 Improving the Accuracy of ex-situ Coral Growth Measurements using 3D-Scanning
David Brefeld[1]*, Valentina Di Mauro*[1]*, Laura J. Fiegel*[1]*, Matthias Y. Kellermann*[1]*, Samuel Nietzer*[1]*, Mareen Moeller*[1]*, Laura Lutjens*[2]*, Sascha Pawlowski*[2]*, Mechtild Petersen-Thiery*[3] *and Peter Schupp*[4]*, (1) Carl von Ossietzky University Oldenburg, Germany, (2)GBP/RA, BASF SE, Germany, (3)BASF SE, Germany, (4) Carl von Ossietzky University Oldenburg; University of Oldenburg (HIFMB), Germany*
Growth measurements in scleractinian corals are important to monitor and evaluate various physiological processes. However, this has been somewhat challenging, especially for small colonies, fragments and over short time periods. This is often the case in laboratory ecotoxicological studies where precise size measurements are essential to reliably detect detrimental effects at high sensitivity.
Common methods for measuring coral size include (1) buoyant weight determination and (2) the evaluation of their footprint (shadow area) from a top-down view. Both methods have notable limitations: (1) buoyant weight measurements can be affected by setup variability, such as minor changes in water temperature or salinity, and the growth of non-target organisms (e.g., algae). (2) Footprint measurements, on the other hand, avoid these issues but may underestimate the complex three-dimensional (3D) growth of corals. However, recent advances in reliable 3D-scanning technologies offer the potential for consistent size measurements with increased accuracy.
In this study, we tracked the growth of three coral species (Montipora digitata, Acropora austera and Porites cylindrica) in an aquarium facility over three months, using buoyant weight, footprint area, and 3D-scanning methods. Small fragments of the coral species were characterized by different growth forms: M. digitata spread encrustingly across hard substrates, A. austera grew in complex shapes along a primary axis and P. cylindrica grew as relatively massive digitate branches. Growth rates were calculated for each species, and the accuracy and correlations among the methods were analyzed. Compared to 3D-scans, we found that buoyant weight measurements showed higher variability, while footprint area measurements were less accurate for corals with more complex growth forms. For encrusting coral fragments, such as M. digitata, footprint area measurements were highly correlated to 3D surface area determinations.
Our findings demonstrate that 3D-scanning offers the highest accuracy of the three tested measurements for coral growth. The evaluation of the footprint area can serve as a precise proxy for less complex growth forms (i.e., M. digitata). Using these improved methods enhances the reliability and sensitivity of growth measurements, paving the way for the use of coral growth as a sub-lethal endpoint in standardized chronic ecotoxicological testing.

Disclaimer/Disclosure: The authors declare that this study received funding from BASF SE (Ludwigshafen, Germany) through the grant Toxicity tests with corals and coral reef communities , grant number 5551622859. Opinions expressed in the paper are those of the authors; the funder had no role in the study design, data collection, analysis or interpretation of the study findings.

4.15.P-Mo400 Octocrylene Shows Ultimate Inherent Biodegradation in OECD Screening Tests
Harald Streicher *and Diego Robles, Beiersdorf AG, Germany*
Octocrylene (CAS 6197-30-4) is a widely used organic compound employed as a UV-B filter in

sunscreens, cosmetics, and various home care products due to its ability to absorb ultraviolet radiation mainly in the UV-B area. In cosmetic formulations, the liquid and oil soluble Octocrylene is not only valued for its photostability and good formulation properties but also for the ability to stabilise Avobenzone, an important UV-A filter. Octocrylene is also used to enhance UV stability in plastics, coatings, and textiles. Concerns regarding its environmental impact have emerged. In the EU, Octocrylene is listed on the Community rolling action plan (CoRAP) as suspected PBT/vPvB.
The REACh-Dossier for Octocrylene concludes the substance to be poorly biodegradable as under test conditions no biodegradation observed. Two studies for ready biodegradability are listed: OECD301F (28d, 1991) & EU Method C.4-D (28d, 1995).
We have studied the biodegradation behaviour of Octocrylene in different tests. We have conducted OECD301 (ready biodegradation, prolonged to 90d), OECD302 (inherent biodegradation, prolonged to 90d) and ISO 14852 (indication for biodegradation, 180d). In our tests, Octocrylene showed biodegradation in all tested systems. A certain lag time was observed until biodegradation started. Result of >70% in OECD302B after 28d allows conclusion as ultimate inherent biodegradable. Values further increase over 90d test time. OECD301B show 16% (30d), 70% (60d) & 75% (90d). Repetitions with different inoculum showed comparable results.
We therefore propose to change the biodegradability assessment of Octocrylene to Ultimate Inherent Biodegradable. We continue to evaluate the environmental performance and re-assess the exposure of Octocrylene in ongoing studies.
It is noteworthy that biodegradation results and lag times match the early 1990s results. OECD301 studies have a longer lag time and exponential growth is observed after the 28d window. OECD302 show similar end results, have shorter lag times and reach plateau faster.

4.15.P-Mo401 Environmental Fate, Hazard and Risk Assessment of the Ultraviolet Filter Bemotrizinol in Water and Soil

Ahmed Tlili[1] *and Marie Collard*[2]*, (1)DSM-Firmenich, Switzerland, (2)DSM-Firmenich, Belgium*

Ultraviolet (UV) filters are essential active ingredients in sunscreens. They provide critical protection against harmful UV radiation and reduce the risk of skin cancer and premature aging. Ideally, effective sun protection should be achieved while ensuring that the UV filters are also safe for ecosystems. In this study, we evaluated the environmental fate, hazards, and risks associated with Bemotrizinol (BEMT), a broad-spectrum UV filter widely used in sunscreens to protect against both UVA and UVB radiation. Our assessment combined a comprehensive, and high-quality experimental data set with in-silico predictions, covering BEMT's environmental fate, transport, exposure, and toxicity.
Our results show that BEMT exhibits a strong affinity for soil and sediment particles due to its high hydrophobicity, resulting in significant adsorption onto organic matter. This property enhances its removal by sludge in wastewater treatment plants and minimizes its mobility in soil, thereby reducing the likelihood of leaching into groundwater or spreading across environments. In aquatic ecosystems, BEMT tends to associate with suspended particulates, further limiting its bioavailability in the water column. Additionally, its low aqueous solubility further mitigates the risk of significant exposure to aquatic organisms.
Our analysis also shows that despite its hydrophobic nature, BEMT has a low potential for bioaccumulation in aquatic organisms, likely due to its large molecular weight. Ecotoxicological studies reveal that BEMT does not cause acute and chronic toxicity to aquatic and soil organisms, including fish, algae, invertebrates, and microbes. Even at concentrations significantly higher than the predicted environmental concentrations, BEMT shows no notable adverse effects (including sub-lethal effects) on these species, indicating no ecological hazard. In conclusion, even in a highly conservative scenario where potentially large amounts of BEMT may enter the environment, its low bioavailability and lack of toxicity ensure that it poses no significant environmental risk.

4.16.P Understanding, Detection, Monitoring, and Management of Harmful Algal Blooms (HABs) and Natural Toxins in the Environment

4.16.P-We401 Microcoleus as Toxic Benthic Mats on Different Bottom Substrates: Ecophysiology and Distribution

Abeer Sohrab and ***Ramesh Goel****, The University of Utah, United States*

Benthic cyanobacteria, notably Microcoleus, contribute to harmful algal blooms globally due to their toxin production. Their thriving in nutrient-poor freshwater environments presents significant environmental and public health challenges. In May 2023, we observed Microcoleus growing in a small tributary of the Virgin River near the Temple of Sinawava. Benthic mats were collected from six sampling points, three each, from rocks and sand substrates and collected rock and sand samples, along with downstream water samples. We aim to understand how these organisms survive in low-nutrient environments, explore interactions between toxic and non-toxic cyanobacteria and other bacteria, and analyze benthic community diversity and growth facilitators using metagenomics. Additionally, we aim to understand the influence of various substrate types on benthic mat composition and growth. An LCMS/MS toxin measurement analysis revealed that all the benthic samples contained anatoxin-a (ATX) (377.13 ±18.05 µg/g) and dihydro anatoxin-a (5.15±0.3 µg/g). ATX (0.377 µg/L) was also present in water samples. Low chlorophyll-a levels and microscopy results suggest the toxin in the water comes from benthic sources, not pelagic algae. The initial metagenomic analysis found that cyanobacteria constituted the majority (>60%) of all benthic mat samples, predominantly belonging to the Microcoleus genus, with <5% attributed to eukaryotic algae. Upon resampling in the fall (October), we observed a complete shift in benthic algae composition, with no presence of Microcoleus. Additionally, no ATX was detected in the algal mats or water samples. We are also studying distinct Microcoleus strains isolated in from same location to compare genotype variations between lab-cultured and environmental samples. Our study, the first to focus on Microcoleus in Zion National Park, reveals adaptive phosphorus acquisition strategies in nutrient-poor conditions. This strain is notably more toxic and contains unique thiamine biosynthesis genes absent in other toxic genomes studied in New Zealand. Supported by NSF funding, ongoing work includes genotypic analysis and microbial interaction studies to better understand Microcoleus proliferation and toxin production. Our research team is also collaborating with experts from New Zealand, Switzerland, the United States Geological Survey (USGS), and the U.S. Environmental Protection Agency (USEPA) to advance our understanding of this cyanobacterium.

4.16.P-We402 Temperature and Salinity Affect Growth and Toxin Production of Estuarine Cyanobacterium Microcystis aeruginosa

Wenxin Liu, *Ilias Semmouri, Colin Janssen and Jana Asselman, Ghent University, Belgium*

Coastal ecosystems, which act as essential connectors between inland waters and ocean systems, are now encountering unparalleled challenges fueled by human activities and climate change. Microcystis aeruginosa is recognized as a harmful cyanobacterial species with its ability to produce microcystins (MCs) and its tendency to bloom in estuarine environments. Although previous research has shown the impact of individual environmental conditions on the growth or toxin production of M. aeruginosa, the possible interactive effects and resulting changes in its toxicity remain uncertain. In this study, we initially conducted an orthogonal growth experiment to evaluate the effects of variations in temperature, salinity, pH, and nutrient conditions. This was followed by a full-factorial growth experiment, with temperature and salinity as primary variables. We measured intracellular and extracellular MCs content, along with phycocyanin levels, during both exponential and stationary growth phases. Toxicity was assessed through mortality and swimming behavior in the harpacticoid copepod Nitokra spinipes and the calanoid copepod Acartia tonsa, both estuarine species. Results indicated that both growth and MCs production were significantly induced by increasing temperatures (15 to 28 °C), but were reduced with elevated salinity levels (8 to 16 ppt). Furthermore, cell density and growth rate showed a strong correlation with both intracellular and extracellular MCs levels. A significant interaction between temperature and salinity was detected, while no correlation was observed between intracellular MCs and phycocyanin levels. Lastly, exposure to M. aeruginosa led to reduced swimming speed, higher inactivity, and increased mortality in A. tonsa compared to the non-toxic Rhodomonas salina, while N. spinipes showed no sensitivity to M. aeruginosa at environmentally relevant concentrations. This study emphasizes the combined effects of temperature and salinity on M. aeruginosa growth and toxin production, shedding light on potential risks associated with future blooms under changing climate conditions.

Disclaimer/Disclosure: The authors thank the Partnership for the Assessment of Risks from Chemicals (No 101057014), UGent Special Research Fund (BOF22/CHN/004) and China Scholarship Council (202206200012).

4.16.P-We403 Portable and Semi-Automated System for Paralytic Shellfish Toxins' Monitoring

*Begoña Espina[1], **Marilia Santos**[1], Miguel Chaves de Sousa[1], Aitor Alvarez[1], Bernardo A. Nogueira[1], Veronica Silva[1], Diogo Cachetas[1], Joana Campos Araujo[1], Laura M. Salonen[2], Adriano Pedro[1], Duarte Mota[1], Marco Martins[1], Carlos Goncalves[1], Ivone Pinheiro[3] and Laura Rodriguez-Lorenzo[1], (1)International Iberian Nanotechnology Laboratory, Portugal, (2)CINBIO, Universidade de Vigo, Spain, (3)International Iberian Nanotechnology Laboratory, Portugal*

Seafood aquaculture is heavily impacted by toxic harmful algal blooms (HABs) yearly. Paralytic Shellfish Toxins (PSTs) are among the most dangerous families of toxins and frequently affect seafood aquaculture. In this work, we describe the development of a portable and semi-automated system for detecting PSTs in seawater, allowing tracking of the appearance and progression of PSTs-producing HABs before the concentration in the seafood reaches regulatory level thresholds. We designed and optimised a modular portable system for real-time in situ implementation. This system requires minimum operator intervention before placing the sample for further processing and analysis. The sample is pumped through a microfluidic chip designed to accumulate and disrupt the cells. The chip features a serpentine channel and a chamber with pillars to confine glass microbeads. Under a portable bath sonication, cells are exposed to mechanical stress, promoting cell walls and membrane breaking and releasing cellular content, including intracellular toxins. The resulting sample is then filtered to remove the debris and encapsulated in microdroplets with a composite formed by a covalent organic polymer, TpPa-COOH and, gold nanostars (GNSs). The TpPa-COOH@GNSs composites serve two purposes: they are used to preconcentrate and trap the biotoxins and enhance the Raman signal of the biotoxin through surface-enhanced Raman scattering (SERS). The microdroplets are accumulated in a microfluidic cartridge, and the read-out is performed using a portable Raman system with a 785 nm laser line. Finally, an automated measurement and analysis is performed using ML/AI algorithms to estimate the PST concentration in the sample. Although the system is still being optimised and the full specifications are being prepared, our results indicate that it can detect nM concentration of PSTs in the microalgae extract from the seawater sample. This system aims to facilitate early warning of HABs, helping to prevent seafood contamination beyond acceptable limits for human consumption and providing a tool to ensure food safety, economic growth, and sustainability of the aquaculture sector.

4.16.P-We404 A Comprehensive Approach to Saxitoxin Effects in Daphnia magna

Albano Pinto[1]*, Ines PE Macario*[1]*, Sergio Marques*[1]*, Joana Lourenco*[1]*, Ines Domingues*[1]*, Jana Asselman*[2]*, Patricia Pereira*[1] *and Joana Luisa Pereira*[1]*, (1)Centre for Environmental and Marine Studies (CESAM), University of Aveiro, Portugal, (2)Blue Growth Research Lab (BGRL), Ghent University, Belgium*

Harmful algal blooms and the toxins produced during these events are a human and environmental health concern that impact fresh and marine waters worldwide. Among them, saxitoxin and its derivatives are of particular interest as potent natural aquatic neurotoxins produced by freshwater and marine algae species. Saxitoxins adverse impacts to human health are well known which prompted the World Health Organization (WHO) to establish a safety guideline for the concentration of these toxins in recreational freshwaters of 30 µg L-1. On the other hand, saxitoxin effects on the aquatic biota are relatively unexplored. To fill some of the existing gaps, this work aims at assessing the effects of a pulse acute exposure (24 h) to 30 µg L-1 of saxitoxin on the model cladoceran Daphnia magna. A holistic approach anchored on the use of biochemical (antioxidant enzymes activity and lipid peroxidation), genotoxicity (alkaline comet assay), neurotoxicity (total cholinesterases activity), behavioral (swimming patterns), physiological (feeding rate and heart rate), and epigenetic (total 5-mC DNA methylation and total DNA methyltransferases activity) biomarkers was used to characterize saxitoxin toxic effects. Exposure resulted in decreased feeding rate, heart rate, total cholinesterases activity, swimming activity and catalase activity. Contrarily, other antioxidant enzymes, namely glutathione-S-transferases and selenium-dependent glutathione peroxidase had their activity increased, along with lipid peroxidation and DNA damage levels. Saxitoxin induced significant differences to epigenetic machinery enzymatic activity (DNA methyltransferases) that translated into significantly altered total DNA 5-mC levels. A putative adverse outcome pathway is proposed to help summarize the sub-lethal effects of saxitoxin on Daphnia magna.

4.16.P-We405 Marinogammarus marinus, Asparagopsis armata and Ostreopsis cf. siamensis: the Good, the Bad and the Villain

Ariana Borges Moutinho[1], Helena David[2], Hugo R. Monteiro[3], Sara Novais[3], Marco F.L. Lemos[3], Carlos Barata Dr[4], Ana Amorim[2] and ***Tiago Filipe da Silva Simoes**[3]*, *(1)Marine and Environmental Sciences Centre (MARE) and Aquatic Research Network Associate Laboratory (ARNET), Polytechnic of Leiria and Universidade de Lisboa, Portugal, (2) Marine and Environmental Sciences Centre (MARE) and Aquatic Research Network Associate Laboratory (ARNET), Universidade de Lisboa, Portugal, (3) Marine and Environmental Sciences Centre (MARE) and Aquatic Research Network Associate Laboratory (ARNET), Polytechnic of Leiria, Portugal, (4)Institute of Environmental Assessment and Water Research - Spanish Council for Scientific Research (IDAEA-CSIC), Spain*

Global environmental changes are linked to the proliferation of harmful algal blooms (HABs) in coastal ecosystems, which can release high concentrations of toxic compounds. These toxins may harm resident biota and disrupt aquatic ecosystem dynamics. Asparagopsis armata is a non-indigenous red seaweed that forms blooms and produces a variety of toxic organohalogens, while Ostreopsis cf. siamensis is a bloom forming unicellular benthic dinoflagellate with conflicting data available about its potential toxicity. This study assessed the ecotoxicological effects of these two algal species on Marinogammarus marinus, a representative coastal amphipod. Juvenile amphipods were exposed to increasing concentrations of macroalgal exudates (0 16%) and microalgal cell densities (0 14,566 cells·mL?¹) for 48 hours to evaluate survival. The LC50 values were determined to be 5.84% for macroalgal exudates and 452 cells·mL?¹ for microalgae. Subsequently, sublethal concentrations (LC10) of each stressor were tested individually and in combination, using a simple binary experimental design. Amphipods were exposed for 48 hours. After exposure, organisms were left to recover during 24h in a clean medium and were transferred to a medium with Fucus sp. Seaweed exudate (food stimulus), and their motility was tracked during 30s. Motility in amphipods was more affected by O. cf. siamensis LC10 than the equitoxic concentration of the exudate from A. armata. amphipods were then tested for biochemical biomarkers indicative of oxidative (lipid peroxidation, LPO) and metabolic (electron transport system activity, ETS) stress, detoxification (glutathione S-transferase, GST), and neuroactivity (acetylcholinesterase, AChE).
Both algal species significantly induced lipid peroxidation and affected neuroactivity in the amphipods, which might be related to motility impairment. The dinoflagellate also inhibited ETS and GST activity, effects not observed with the macroalga and suggesting broader routes of toxicity by the dinoflagellate. Despite their distinct toxicity mechanisms, both species demonstrated significant negative impacts on M. marinus, highlighting potential risks to coastal trophic dynamics and ecosystem stability.

4.16.P-We406 Hazard Characterization of the Marine Toxin Ovatoxin-a at the Skin Level

Michela Carlin[1], Alessandra D'Arelli[1], Silvio Sosa[1], Michela Varra[2], Luciana Tartaglione[2], Valentina Miele[2], Valeria Tegola[2], Chiara Melchiorre[2], Martina Carelli[2], Carmela Dell'Aversano[2], Aurelia Tubaro[1] and ***Marco Pelin**[1]*, (1)University of Trieste, Italy, (2)University of Naples Federico II, Italy*

Ovatoxin-a (OVTX-a) is the major palytoxin (PLTX) analogue identified in the benthic dinoflagellate Ostreopsis cf. ovata from the Mediterranean Sea. In this area, the risk for human health during O. cf. ovata blooms is mainly associated with inhalation of marine aerosol and/or skin contact with seawater. Despite the hazard posed by PLTX has been extensively characterized in the last decades, very few data are currently available for OVTX-a. Hence, this study was aimed at characterizing in vitro the hazard posed by skin exposure to OVTX-a, using spontaneously immortalized HaCaT keratinocytes as human epidermal cells.
The effects of OVTX-a (1x10-16-1x10-7 M) in HaCaT cells were compared to those of the reference toxin (PLTX) in terms of cell viability, cell necrosis, reactive oxygen species (ROS) production and mitochondrial depolarization. After 4 h exposure, OVTX-a induced a concentration-dependent cell viability reduction (EC50 = 8.3x10-9 M), with one order of magnitude lower potency than that of PLTX (EC50 = 3.7x10-10 M). Accordingly, OVTX-a induced a concentration-dependent increase of cell necrosis, with a potency lower than that of PLTX. Moreover, OVTX-a increased ROS production similarly to PLTX, but it caused a lower mitochondrial depolarization in keratinocytes with respect to the reference toxin. Even though with a different potency, OVTX-a and PLTX appear to induce these effects with a similar molecular mechanism as assessed co-exposing the cells to ouabain (OUA, 1.0x10-5 M), an

inhibitor of Na+/K+ ATPase and molecular target of PLTX, or diphenyliodonium chloride (DPI, 5.0x10-6), a non-specific inhibitor of flavoprotein-based enzymes known to be involved in PLTX-induced oxidative stress.
In addition, a particular focus was given to the inflammatory potential of OVTX-a, exposing HaCaT keratinocytes to its subcytotoxic concentrations up to 24 h, and analyzing the release of a panel of cytokines, chemokines (IL-1?, IL-1?, IL-6, IL-7, IL-8, IL-18, IL-33, TNF-?, IFN-?, MCP-1, RANTES, GM-CSF, MIF, ECF-CCL11) and prostaglandin E2 (PGE2). In general, only the release of few cytokines (IL-6, IL-8, TNF-?) and PGE2 was significantly increased by OVTX-a exposure , albeit with a lower potency as compared to PLTX.
In conclusion, this study provides new evidences for the characterization of the hazard posed by OVTX-a towards skin keratinocytes.

4.16.P-We407 Detection of Potential Metabolites of Cylindrospermopsin in Rat Brain After Oral Exposure and Effects on Acetylcholinesterase Activity and on Oxidative Stress Biomarkers

Cristina Plata-Calzado, *Ana I. Prieto, Antonio Cascajosa-Lira, Antonio Casas-Rodriguez, Leticia Diez-Quijada, Ana Camean and Angeles Jos, Universidad de Sevilla, Spain*

Cylindrospermopsin (CYN) is a cyanotoxin of increasing interest due to its toxicity and worldwide distribution. The liver is considered its main target organ, however, different studies show adverse effects also on other organs, including the brain. Despite this, few studies have focused on the impact of CYN on the nervous system and only two of them have determined the presence of CYN in brain of fish by enzyme-linked immunosorbent assay (ELISA). Moreover, to our knowledge, no studies have been performed in mammals with pure CYN. Therefore, this work is focused on the determination of CYN and its potential metabolites in the brain of male Wistar rats after oral exposure for 48 h to three different doses of pure CYN (7.5, 23.7 and 75 µg/kg body weight) by ultra-high performance liquid chromatography coupled to a tandem mass spectrometry system (UHPLC-MS/MS). In addition, in order to determine the toxic effects of CYN on this organ, several biomarkers of oxidative stress, such as superoxide dismutase (SOD) and catalase (CAT) enzyme activities and lipid peroxidation (LPO) and glutathione (GSH) levels were evaluated, as well as the enzymatic activity of acetylcholinesterase (AChE). Although CYN was not detected in brain, up to 14 potential CYN metabolites produced by different metabolic pathways were identified. These potential CYN metabolites could arise via several routes, including phase I reactions: hydration, oxidative deamination to alcohol or oxidative deamination to ketone or phase II reactions, such as acetylation, methylation or conjugation reactions with glutamine, cysteine or arginine among others. Furthermore, the results showed a significant increase in SOD (1.7-fold) and CAT (1.3-fold) activities after exposure to the highest dose tested and a dose-dependent increase in LPO levels. However, no changes in GSH levels were detected. Regarding AChE activity, a significant reduction was observed at all doses used. Therefore, the observed alterations could be induced by CYN metabolites detected. This is the first study to link alterations at brain level to the presence of CYN metabolites. These results highlight the need for further studies focused on the potential adverse effects of CYN and its metabolites on the mammalian nervous system and its possible role in neurodegenerative diseases.

4.16.P-We408 In Vitro Assessment of the Immunomodulatory Effects of Natural Lichen Extracts on Human Lymphocytes

Yasser Essadki[1], Leticia Diez-Quijada[2], Antonio Casas-Rodriguez[2], ***Cristina Plata-Calzado[2]****, Fatima El Khalloufi[3], Brahim Oudra[1], Alexandre Campos[4], Vitor Vasconcelos[4], Angeles Jos[2] and Ana Camean[2], (1) Cadi Ayyad University, Morocco, (2) Universidad de Sevilla, Spain, (3) Sultan Moulay Slimane University of Beni Mellal, Morocco, (4) CIIMAR, Interdisciplinary Centre of Marine and Environmental Research, University of Porto (FCUP), Portugal*

Lichens are symbiotic organisms known for their distinctive secondary metabolism. The metabolites produced by lichens demonstrate a variety of pharmacological activities, including antibacterial, antioxidant, and antiproliferative effects. Pseudevernia furfuracea (L.) Zopf is a lichen present in different localities in Morocco whose extracts have been previously characterised, with atraric acid as the main component. The purpose of this work was to assess the impact of two lichen extracts (HE1, HE2) in representative cells of the immune system, the Jurkat cell line (lymphocytes). The results showed that both extracts reduced cell viability after 24 hours of exposure. The mean effective concentrations 50 (EC50) were 55.20 ± 7.06 µg/mL for HE1 and 56.86 ± 4.05 µg/mL for HE2. In addition, cell death mechanisms were investigated by flow cytometry, being the apoptosis and late apoptosis the predominant processes after 24 and 48 hours of exposure, respectively. Moreover, the mRNA expression of various cytokines was studied by RT-qPCR. Among them, interleukin 2 (IL-2) and interferon-gamma (INF-?) levels were up-regulated after 24 hours of exposure to both HE1 and HE2, while a down-regulation was observed in the tumor necrosis factor-alpha (TNF-?) under the same experimental conditions. After 48 hours of exposure, only up-regulation of IL-2 was observed. Overall, these findings suggest that both extracts could have immunomodulatory effects in vitro. Further research is needed to determine the mechanisms involved and the impact of HE1 and HE2 on the human immune system.

4.16.P-We409 A MALDI-MSI-Based Approach to Characterize the Spatial Distribution of Cylindrospermopsin and Lipid Alterations in Rat Intestinal Tissue

*Antonio Casas-Rodriguez[1], Cristina Lopez-Vazquez[2], Remedios Guzman-Guillen[1], **Cristina Plata-Calzado**[1], Eduardo Chicano-Galvez[2], Ana Camean[1] and Angeles Jos[1], (1) Universidad de Sevilla, Spain, (2) University of Cordoba, Spain*

Anthropogenic activities and climate change are exacerbating the proliferation and distribution of cyanobacteria, which produce harmful cyanotoxins like cylindrospermopsin (CYN). This toxin poses significant risks to both ecosystems and human health. Ingestion of contaminated food and water is the primary route of CYN exposure, underscoring the importance of monitoring its absorption, distribution, and potential health effects. In that sense, matrix-assisted laser desorption/ionization time-of-flight mass spectrometry imaging (MALDI-MSI) offers a powerful tool for visualizing the spatial distribution of a wide range of molecules. This study aimed to develop and optimize a novel MALDI-MSI method for CYN detection in rat intestinal tissue. To investigate the quantitative spatio-temporal distribution of the toxin, mid-intestinal samples were collected from rats exposed to 500 µg CYN/kg body weight and sacrificed at 0, 2, 4, 6, and 24 hours post-exposure. Cryosections of fresh intestine tissue (jejunum) were obtained at 10 µm, mounted in MALDI IntelliSlides and frozen until use. The slides were allowed to reach room temperature during a 30 min drying step using a vacuum pump, and the DHB matrix was applied over the entire surface of the slide by using a HTX TM-Sprayer. MALDI-MSI experiments were carried out in positive ionization mode, within a m/z range of 300-1350 and an ion mobility range from 0.8 1.68, using a timsTOF-FleX mass spectrometer. Additionally, the impact of CYN on the intestinal lipid profile was assessed. The results showed that the method developed was useful to detect and quantify CYN and its sodium and potassium adducts in rat intestine. Moreover, the method was validated for linearity, sensitivity, and precision using mimetic tissue sections spiked with various CYN concentrations (0.1-100 ppm), ensuring its suitability for visualizing CYN, and its sodium and potassium adducts distribution in the rat tissue. Regarding lipid profile, significant alterations in several lipid families were observed, suggesting an inflammatory response, increased oxidative stress, and progressive damage to cell membrane integrity. Further research is necessary to elucidate the distribution of CYN in other vital organs, such as the liver, kidney, and stomach.

4.16.P-We410 Assessing the Effects of Phycotoxin Mixtures on Marine Zooplankton: Insights from Copepod Responses at Different Life Stages

***Wenxin Liu**, Ilias Semmouri, Luca Deroma, Colin Janssen and Jana Asselman, Ghent University, Belgium*

The expansion of human activities into oceans and lakes has profoundly disrupted aquatic ecosystems. Over recent decades, HAB occurrences have increased due to mounting anthropogenic pressures. Harmful algal blooms (HABs) are a phenomenon occurring hen certain primary producers, capable of generating toxic metabolites (phycotoxins) proliferate excessively. These phycotoxins can accumulate in fish and shellfish, subsequently moving up the food web and adversely affecting organisms at higher trophic levels, ultimately posing significant risks to human health. Phycotoxins are classified into five main groups based on their effects: paralytic shellfish poisoning (PSP), amnesic shellfish poisoning (ASP), neurotoxic shellfish poisoning (NSP), diarrhetic shellfish poisoning (DSP), and azaspiracid poisoning (AZP). While the individual effects of these toxins are well-documented, the combined effects on the marine food chain remain less understood. Copepods are key primary consumers in marine ecosystems, acting as vital links to higher trophic levels, such as planktivorous fish. They also play an essential role in oceanic biogeochemical cycling, for example through carbon C and nitrogen export to deeper waters. This study, therefore, examines the effects of mixed phycotoxin exposure on two copepod species: the epibenthic copepod Nitokra spinipes and the planktonic copepod Acartia clausi. We investigated the impacts of two harmful algal species, Protoceratium reticulatum and Alexandrium minumtum, using a full factorial design that included environmentally relevant concentrations of both living algae, as well as their extracts. After 48 hours of exposure to these mixtures, we evaluated the response of adult copepods for swimming speed, inactivity, and mortality using the ZebraBox device, while naupliar immobility was assessed under a light microscope. Our research aims to enhance understanding of the impacts and mechanisms of mixed HAB exposure on copepods, contributing to broader insights into potential risks to ecosystems and human health.

4.16.P-We411 A Step Closer to Link LC-PUFA Fatty Acids and Toxin Biosynthesis in Toxic Dinoflagellates

***Tiago Filipe da Silva Simoes**[1], Ariana Borges Moutinho[1], Katie Shiels[2], Sara Novais[1], Marco F.L. Lemos[1], Helena David[3], Ana Amorim[3], Emma Murphy[2] and Patrick Murray[2], (1) Marine and Environmental Sciences Centre (MARE); Aquatic Research Network Associate Laboratory (ARNET), Polytechnic of Leiria, Portugal, (2)Shannon Applied Biotechnology Research Centre, TUS, Ireland, (3) Marine and Environmental Sciences Centre (MARE); Aquatic Research Network Associate Laboratory (ARNET), Universidade de Lisboa, Portugal*

Long-chain polyunsaturated fatty acids (LC-PUFAs) are essential for many physiological processes in marine organisms. While these compounds are typically associated with health benefits in higher trophic levels, emerging evidence suggests that their presence in toxic harmful algae species (HABs) may be related to toxicity. While direct evidence is limited, PUFAs might serve as biochemical precursors or modulators in the biosynthetic pathways of certain algal toxins. In dinoflagellates it is believed that synthesis of some FAs and toxins share the same anaerobic Polyketide Synthase (PKS) pathway. This study explores the potential role of LC-PUFAs as proxies for toxin production in the benthic harmful dinoflagellates Prorocentrum lima and Amphidinium carterae. Both species are known for their production of bioactive secondary metabolites such as okadaic acid and amphidinols, respectively, potentially harmful to marine biota. Here, the toxicity of dinoflagellate species was firstly evaluated and validated through lethal effects (LC50) in marine microinvertebrates (artemia and amphipods). The levels of specific fatty acids were then correlated with the most common toxins in both dinoflagellate species, after culturing them at different temperatures (15ºC, 19ºC and 24ºC), until both reached the end of their exponential growth phase. Results revealed strong positive correlations, mostly between EPA and DHA, and th e quantity of toxins identified in both species.

Understanding these mechanisms is critical for predicting the ecological impacts of HABs, as disentangling the specific relation of particular fatty acids and other algal metabolites with overall toxins and their toxicity may become crucial in understanding and mitigating HABs effects on marine food webs.

4.16.P-We412 A Hyalella azteca Transgenerational Biotest to Screen Reproductive and Embryonic Development Effects of MC-LR and Exudates from Cyanobaterial Toxic Strains

***Thalita Tieko Silva**[1], Olivier Geffard[2], Herve Queau[2], Laura Garnero[2], Arnaud Chaumot[2] and Sueli Borrely[1], (1)Instituto de Pesquisas Energeticas e Nucleares IPEN/CNEN-SP, Brazil, (2)Laboratoire d Ecotoxicologie, INRAE - Riverly, France*
Microcystis aeruginosa is known to its capacity to produce toxic secondary metabolites. These compounds pose a significant risk to water quality, human health, and wild life. Several studies pointed the effects of these compounds on invertebrates. However, the utilization of amphipods as a model organism remains limited. Based on a new two-week biotest, the aim of this study was to investigate the reproductive responses of H. azteca exposed to the cyanotoxin MC-LR (model substance) and MaE (complex mixture), and to evaluate their effects on the parental and F1 generations. Cyanobacteria was cultivated under controlled conditions until it reached a state of growth stabilization. The MaE was collected and assays were performed using a concentration of 100%. For the MC-LR toxin, tests were carried out at concentrations between 0.3 and 27µg/L. Couples in the post-molt stage were exposed to controls, MC-LR and MaE solutions for six days. The survival of both sexes, progress of females in the molting stage, number of embryos present in females marsupium, and the stage of embryonic development were recorded. To assess the effects of parental exposure on fertility, the assays continued in uncontaminated water for a total of 13 days to measure the new production of F1 embryos correspondent to the first post-exposure laying event. At this point, the survival and body size of the females, number of embryos, embryonic development and malformation were evaluated. The results demonstrated that the survival of the organisms was not affected (at least 85% of survival in all samples). With regard to the reproductive response, MC-LR and MaE accelerated the molting process in females, although fertility was not affected. With respect to the embryonic development, no disorders were clearly observed when females were exposed to both samples. Consequently, it can thus be concluded that the MC-LR toxin has the potential to disrupt the molting dynamics of H. azteca females, a hypothesis that can be confirmed through the analysis of MaE responses since the strain in question is known to produce MC. The subsequent step will be to evaluate the effects observed in the F1 generation following parental exposure. The new findings of this endocrine disruption potential in the amphipods paves the way for future applications of Hyalella biotest for biomonitor the occurrence and the toxic potential cyanobaterial toxic strains in the aquatic environment and water resources.

4.16.P-We413 Cyanobacteria Survival After Exposure to UVB Radiation

*Ines PE Macario[1], **Albano Pinto**[2], Joana Luisa Pereira[2] and Felipe Gomez[1], (1)Centro de Astrobiologia (CSIC-INTA), Spain, (2)Centre for Environmental and Marine Studies (CESAM), University of Aveiro, Portugal*
In the context of climate change, shifts in global temperature and increased solar radiation are altering aquatic ecosystems, enhancing the frequency and intensity of harmful algal blooms (HABs). Cyanobacteria, a dominant group in many freshwater and marine environments, are sensitive to changes in ultraviolet-B (UVB) radiation a factor exacerbated by ozone depletion and atmospheric alterations. UVB exposure triggers oxidative stress in cyanobacteria, potentially impacting their survival and ecological dynamics. This study investigates the survival rates and oxidative stress responses of Nostoc sp. PCC 7906 under controlled UVB exposure (1 min, 30 min, 1 h, and 3 h), aiming to better understand how these organisms may adapt or become vulnerable in a changing climate. A comprehensive array of biochemical biomarkers, namely the activity of the main antioxidant enzymes and thiobarbituric acid reactive substances (TBARS) levels as an indicator of oxidative stress onset were evaluated immediately after the exposure and then again after a recovery period of 38 days of culturing, to observe if antioxidative defense mechanisms could help exposed organisms recover from the damage caused by UVB.
Results showed that even the longest exposure (3 h) was not enough to kill the cells. Although their growth was impaired at the beginning, after ca. 1 week recovery, the cells started to grow and surpassed all the other treatments. Regarding the antioxidative metabolism, catalase was the only enzyme with its activity significantly increased in response to shorter exposures (1 and 30 min), while after 1 h and 3 h of exposure to UVB, the other antioxidative enzymes such as Glutathione reductase and Glutathione S-Transferase also had their activity significantly increased. TBARS levels were also significantly higher in cells exposed for longer (1 h and 3 h). These results seem to suggest that, despite the activation of the antioxidative defenses, UVB exposure caused oxidative stress. However, oxidative damage was higher immediately after the exposure, and diminished with time, suggesting that specific repair mechanisms were activated by the cells.

4.16.P-We414 Developing High Throughput Screening Approaches to Characterize Cyanobacterial Sensitivity to Herbicides

*Andrew Barrick, Rie Watanabe and **Tham C. Hoang**, Auburn University, United States*

Development of novel herbicides to address cyanobacteria blooms often utilize flask-based experiments to identify sensitivity thresholds. Different cyanobacteria are sensitive to different herbicides, and it is challenges to adequately define effect concentration (EC) thresholds using current methodologies. High throughput approaches using microplates can streamline testing. However, there are nuances in growing conditions that can influence the results. The research had several aims: 1) investigate differences in growth rates and quality of cyanobacteria in flasks and microplates, 2) assess whether there were differences in interpretation of herbicide toxicity between the two culturing methods, and 3) identify the best method for investigating herbicide toxicity towards cyanobacteria. The study utilized Microcystis aeruginosa (UTEX 3037) due to their capacity to form uniform test suspension and relatively easy growing conditions. Microcystis aeruginosa were grown in flasks and microplates and cell viability and abundance was counted through flow cytometry for two weeks. Throughout the experiment, cell viability was maintained at greater than 99% in both the flask and microplate. Density of viable cells initially lagged in the microplate however, density increased rapidly on day 3 and exceeded densities of M. aeruginosa grown in the flasks on days 7, 11, and 14 demonstrating that growing conditions in the microplate did not M. aeruginosa. The previously described method was used to identify if dose response thresholds for copper were influenced by culturing method. Microcystis aeruginosa were exposed to copper using six treatments ranging from 5 to 160 µg/L. Chlorophyll and phycocyanin were measured through fluorescence using a microplate reader and cell viability and density were characterized through flow cytometry. Effect concentration thresholds demonstrated consistency between microplates, highlighting inter-plate reliability, and comparability to the flask cultures. Results demonstrated that high throughput screening approaches can be designed to investigate effects herbicides on M. aerguinosa and that culturing conditions in the microplate did not influence the interpretation of copper ecotoxicity. Follow-up research is needed to validate the high throughput approach for other cyanobacteria. Research investigating the capacity of microplates to characterize the ecotoxicity of hydrophobic chemicals is also needed to verify the method developed.

Track 5. Life Cycle Assessment and Footprinting

5.01 Pushing the Limits: Incorporating Absolute Limits in Life Cycle Assessment

5.01.T-01 Sustainability Challenges of Global Hydrogen Supply in the Context of Planetary Boundaries

***Jesmyl Cordova Cordova** and Carlos Pozo, Universitat Rovira i Virgili, Spain*

As global decarbonization efforts accelerate, hydrogen is increasingly recognized as a crucial energy carrier for the transition to a low-carbon future. However, the environmental assessment of hydrogen supply chains, including both production and transportation, within the framework of planetary boundaries (PB), remains insufficiently explored on a global scale.

This study addresses this gap by evaluating the environmental impacts of 800 potential global hydrogen supply chains, obtained by combining 32 production methods and 25 transportation options. The former include steam reforming, water electrolysis with bioenergy and carbon capture and storage (WE-BECCS), and aluminium combustion, among others. Transportation methods cover options like compressed hydrogen, liquid hydrogen, and liquid organic hydrogen carriers, all using pipeline, trucks or ships. Each alternative is evaluated in six regions before results are aggregated at the global level, thus capturing the influence of regional factors. We evaluate the global impacts of these hydrogen supply chains using the Planetary Boundary-Life Cycle Impact Assessment (PB-LCIA) method, which allows us to express life cycle inventories as impacts caused on ten control variables for the PBs.

Findings reveal that hydrogen is currently responsible for 15% of global impacts on CO2-based control variables, using already 40% of the safe operating space (SOS) for all anthropogenic activities. Among the 800 hydrogen supply chains assessed, only 205 reduce PB transgressions compared to BAU. The most sustainable option is WE-BECCS with Miscanthus, which keeps Energy imbalance and CO2 concentration PBs within the SOS, but pressures biodiversity due to increased land use. Aluminium

combustion outperforms WE with PV or wind thanks to avoided treatment of aluminium scrap. Interestingly, WE powered with current electricity mixes does not improve the BAU scenario. Compressed hydrogen by pipeline emerges as the best option for transportation, although this depends on the distance and the region. In China, combining this option with WE-wind losses to BAU from 1000 km upwards, while this breakeven distance is 2500 km in Europe. Hence, hydrogen policies must not only focus on production but also address the environmental impacts of transportation, as they could offset production gains.
This study highlights that the best options to decarbonize hydrogen supply must align with transitions in other sectors, which vary by region.

5.01.T-02 Current Aviation Roadmaps are not within Planetary Boundaries

Bastien Païs[1]*, Alexandre Gondran*[2]*, Lorie Hamelin*[3] *and Florian Simatos*[1]*, (1)ISAE-Supaero, France, (2)ENAC, France, (3)Toulouse Biotechnology Institute, France*

Background and purpose: The aviation sector is a significant contributor to global warming, accounting for almost 4% of effective radiative forcing. In order to assess its climate footprint over time, the sector and its various stakeholders have developed numerous prospective scenarios incorporating different assumptions about traffic growth, fleet renewal, introduction of new technologies, and the use of alternative fuels. However, the various solutions proposed are only assessed through the prism of climate.

By reducing the scale from global to sectoral, the Planetary Boundaries (PB) framework can be used to perform an Absolute Environmental Sustainability Assessment (AESA) of contrasted prospective scenarios for the aviation sector.
Based on recently developed tools and methodologies, this study brings methodological and conceptual advancements to enable dynamic and prospective AESAs and present applications to aviation prospective scenarios.

Methods: This study uses and develops the PB-LCIA methodology, which links LCA to the PB framework. By using the premise tool and developing a dynamic approach to impact assessment, it develops a new methodology for prospective and dynamic AESA.
It also deploys and develops the "Fulfilment of Human Needs" approach of Heide et al. which is based on the notion of sufficientarianism to share PB budget between different human activities.

Results: Historical aviation already exceeds its PB budget for climate change, biosphere integrity, and nitrogen cycle. Scenarios using alternative fuels have a lower climate impact than the 100% fossil fuel scenario, but generate new potential environmental problems, such as the disruption of the phosphorus cycle. Among the 217 scenarios studied, none can be classified as absolutely sustainable.

Conclusions: By using new tools and developing an appropriate methodology, our work highlights the potential and the limits of alternatives fuels to reduce the environmental impacts of aviation. It also shows the absolute environmental unsustainability of the aviation sector. Furthermore, the development of this methodology opens the possibility of conducting prospective and dynamic AESAs for other sectors of activity, enabling the anticipation of sustainability issues as well as the displacement of environmental problems in a context of decarbonization of activities.

5.01.T-03 Is the UK Consumption within Planetary Boundaries? A Supply Chain Perspective

Qiang Yang *and Andrea Paulillo, University College London, United Kingdom*

The Planetary Boundaries (PBs) framework has been operationalized at national and regional scales to evaluate absolute environmental sustainability. However, studies tracing the pressure leading to PBs transgressions in an integrated and comprehensive perspective remain limited. This study presents an absolute environmental sustainability assessment (AESA) of UK consumption that focuses on tracing impacts from domestic production and foreign production (i.e. imported goods and services). The UK s consumptive environmental footprints are derived via an environmental extended multi-regional input-output analysis (EEMRIOA) with the Exiobase database, and then translated into PBs-related metrics through a refined regional-specific characterisation factors (CFs) model. Sectoral contribution analysis revealed that the agricultural and transport sectors are the two largest contributors to most PBs transgressions. Time series analysis demonstrates that while the UK's climate change-related PBs pressure has declined over time, the country still exhibits significant transgressions due to outsourcing impacts to climate-intensive imported products. Other agriculture-related PBs, such as freshwater use, biogeochemical flows, and land system change present substantial increases over time and may trigger regional PBs transgressions in other supplier countries. The findings suggest that net importing countries like the UK should not only look at adjusting their consumption patterns, but also potentially better scrutinize their international trading partners. The study also highlights the importance of the supply chain perspective for comprehensive national/regional-level AESA.

5.01.T-04 Aligning Science-Based Targets with Consumer Needs: A New Method for Setting Climate Goals for Products

Teddy Serrano, *Solene Boivent, Anders Bjorn and Michael Hauschild, Technical University of Denmark, Denmark*

Operating within the Earth's carrying capacities requires the allocation of environmental budgets and targets at more granular levels, such as at the company level. Current frameworks, like the Sectoral Decarbonization Approach, developed by the Science-Based Targets initiative, focus on production intensity targets, which overlooks the role of products in fulfilling societal needs. This study explores the development of a new methodology that connects the allowed climate impact of companies products to their ability to fulfill the needs of final consumers.

The framework begins with a global emissions scenario aligned with the Paris Agreement to 2050, allocating budgets at country level based on an equal per capita approach. National budgets from 2022 to 2050 are distributed across functions, with 2022 reflecting current patterns and 2050 aligning with basic needs, defined by emissions from the lowest-impact households. In parallel, activity levels to 2050 are projected under two scenarios: business-as-usual (BAU) and sufficiency, setting upper and lower boundaries. Dynamic intensity targets, expressed in kg CO?-eq per functional unit, are derived from the ratio of allocated budgets to activity levels.

This methodology is applied to short-distance mobility in Denmark and Spain as a proof-of-concept. The intensity targets are compared to the impact of current available technologies, calculated using LCA. This approach identifies when a product may become unsustainable in absolute terms or determines the rate of improvement needed for it to stay within its allocated environmental limits. Results highlight that sufficiency measures, such as limiting consumption to decent living standards, increase environmental space per activity unit, easing the pressure on technologies to meet stringent thresholds.

While this framework is designed for business-to-consumer companies, it can be expanded to business-to-business ones by linking their activities to the end products they support. Future research can also refine the methodology using prospective life cycle assessments to monitor technological alignment with dynamic targets.

5.01.P-Mo402 Inclusion of Albedo-Induced Climate Impacts of Land Use in Planetary Boundaries-based Life Cycle Assessment

Kathryn Loog[1], *Anders Bjorn*[2] *and Manuele Margni*[3], *(1)CIRAIG, Polytechnique Montreal, Canada, (2)Centre for Absolute Sustainability and the Section for Quantitative Sustainability Assessment, Technical University of Denmark, Denmark, (3)CIRAIG, Polytechnique Montreal; Institute of Sustainable Energy, School of Engineering, HES-SO Valais Wallis, Switzerland*

Land-use changes affect the climate not only through greenhouse gas (GHG) emissions but also through changes to biogeophysical properties such as surface albedo the fraction of solar radiation reflected by the earth's surface. Changes to the surface albedo alter the earth s energy balance causing radiative forcings that can rival the climate impacts of GHG emissions. The planetary boundaries framework highlights surface albedo changes as a key anthropogenic driver of climate change, alongside GHG and aerosol emissions. Despite this, the integration of albedo-induced impacts into in life cycle assessment (LCA) and absolute sustainability assessment such as planetary boundaries-based LCA (PB-LCA) remains limited. This study presents a spatially and temporally differentiated method to quantify the climate impacts of surface albedo changes. We developed localized monthly characterization factors for various land use types using potential natural vegetation as a baseline to represent preindustrial conditions. We determined surface albedo changes by combining satellite data with a novel algorithm to predict the albedo of multiple land cover types for the same location. Methods to calculate the impacts both in radiative forcings (consistent with the planetary boundaries control variable) and kg CO2e (consistent with more traditional LCA impact assessment methods) are presented. The results show that the albedo-induced climate impacts often greatly exceed the planetary boundary of +1W/m2 at local scales. However, to adequately compare these localized limits to this global boundary, it likely needs to be downscaled to local levels. There is also pronounced intra-annual variability in the impacts, particularly in more northern regions, meaning that the boundary could be transgressed in only some months of the year, which still has the potential to trigger non-reversible tipping point reactions. However, for several land use types investigated here, the impacts are largely negative, reducing the climate burden. The albedo-induced climate impacts can indeed contribute to the potential transgression of the climate change boundary, especially when considering intra-annual variations. This demonstrates the importance of including these impacts into absolute sustainability assessments such as PB-CA. Impacts are also calculated in units of kg CO2e, which is a less relevant metric for PB-LCA but is included to facilitate use with more traditional impact assessment methods.

Disclaimer/Disclosure: The authors would like to acknowledge the financial support of the industrial partners of the Consortium on Life Cycle Assessment and Sustainable Transition (a research unit of the CIRAIG). The authors remain solely responsible for the content of this study.

5.01.P-Mo409 A Boundary for Global Abiotic Resource Use: Constraints from Limited Regional Water Availability

Kamrul Islam[1]*, Keitaro Maeno*[1]*, Ryosuke Yokoi*[1]*, Damien Giurco*[2]*, Shigemi Kagawa*[3]*, Shinsuke Murakami*[4] *and Masaharu Motoshita*[1]*, (1)National Institute of Advanced Industrial Science and Technology, Japan, (2)University of Technology Sydney, Australia, (3)Kyushu University, Japan, (4)The University of Tokyo, Japan*

Abiotic resource production is essential for global economic development and the transition to low-carbon technologies but comes with significant environmental consequences, particularly through the use of regionally available water. This study examines the global production capacity of 32 abiotic resources, considering regional water availability as a key constraint. Our analysis reveals that current abiotic resource production exceeds water availability, with copper production in 2010 surpassing local water capacity by 37%. Relocating production to areas with lower water stress could alleviate these exceedances; however, economic factors often limit the feasibility of such shifts. Additionally, projected future demand for abiotic resources is expected to increase water consumption significantly. Incorporating water resource constraints into production strategies is crucial to ensuring sustainable resource management.

5.01.P-Mo410 Using Absolute Limits at Regional Level: Is Flanders Living Within its Fair Share of the Planetary Boundaries?

Karolien Peeters*, An Vercalsteren and Maarten Christis, Flemish Institute for Technological Research (VITO), Belgium*

Flanders, a region in Belgium, faces numerous challenges in maintaining a high-quality living environment. The Planetary Boundary (PB) framework is a widely recognised tool for assessing the stability of Earth System (ES) processes. This study explores the applicability of the PB framework in Flanders policy context, focusing on its potential to monitor the region s contributions to global and local environmental impacts. The research question is: Is Flanders living within its fair share of the planetary boundaries?

Applying the PBs concept at a sub-global scale requires translating globally defined limits to a regional context, a process that involves normative choices. Downscaling of the PBs to delineate the safe operating space for Flanders was done by applying the allocation principles Equality, Needs, Right to development, Sovereignty, Capability as proposed by EEA/FOEN. Each PB is assessed through control variables, yet these often differ from the indicators currently used by Flanders. The study involved the identification of the most appropriate control variables or proxy indicators for Flanders across all PBs.

The Flemish environmentally extended multi-region input-output (EE MR-IO) model was used to calculate footprint indicators for Flanders, where not yet available. By comparing these footprints with the safe operating space for Flanders, the study determined whether Flanders exceeds its fair share of the PBs. This analysis was done for those PBs for which regional data were available or could be easily calculated, being climate change, biosphere integrity, land system change, biogeochemical flows and freshwater use.

The study reveals that Flanders exceeds its safe share for four out of five ES processes, with freshwater use being the only exception. However, further research is necessary to define the best suitable proxy indicators to monitor PBs in Flanders, especially to address specific regional environmental issues. The study incorporated elements of Life Cycle Assessment (LCA) to define the boundaries for climate change and biosphere integrity. However, the overall contribution of LCA remained limited. Conversely, useful insights were gained for applying absolute sustainability assessment within LCA. EE MR-IO models demonstrated potential for calculating sectoral contributions to ES process, providing a basis for setting sector-specific targets.

5.01.P-Mo403 Developing Characterization Factors and Carrying Capacities for Land Use Impacts on Ecosystem Functions Provision

Zongyue Zhang[1]*, Anders Bjorn*[1]*, Sumesh Sukumara*[2]*, Samir Meramo*[2] *and Michael Hauschild*[1]*, (1)Section for Quantitative Sustainability Assessment, Technical University of Denmark, Denmark, (2)The Novo Nordisk Center for Biosustainability, Technical University of Denmark, Denmark*

Anthropogenic land-use activities are the major cause of the Earth s biodiversity loss and therefore the exceedance of the planetary boundary for biosphere integrity, whose functional component is currently defined as the Human Appropriation of the biosphere s Net Primary Production (HANPP) smaller than 10% of the biosphere s net primary production. The focus on the potential loss and change of ecosystem functions from human activity like land use is complementary to more conventional indicators of loss in species richness and abundance.
In the community of life cycle impact assessment, a more complex set of Functional Diversity (FD) metrics, comprising Functional Richness (FRich), Functional Evenness (FEve), and Functional

Divergence (FDiv), have recently been proposed for measuring land use impacts on ecosystem function provision. It is currently unclear whether the HANPP indicator or the FD indicators are most sound for Absolute Environmental Sustainability Assessments (AESA). Regional boundaries (i.e., regional carrying capacities) for the FD indicators have not yet been quantified.
To fill this gap, we conduct an analysis to present 1) Sets of comparable Characterization Factors (CFs) for land-use impacts on ecosystem functioning taking HANPP and the FD metrics as indicators, at the same spatial resolutions within Europe and 2) regional boundaries estimation for each indicator. Databases of plant traits, vegetation plots, patterns of land use and land cover, and HANPP are integrated to derive the CFs. To quantify the regional boundaries for the FD indicators, we rely on the identification of non-linearities in FD indicator values across different land use types for each natural vegetation zone. Tentative results demonstrate that the FRich of land is more significantly altered than FEve and FDiv under current land use patterns, and results of the FD indicators present patterns that do not fully overlap with those of the HANPP indicator. The final results are expected to reveal under what circumstances, if any, the HANPP indicator can serve as a reasonable proxy for the FD indicators in AESA. Following additional research, CFs for ecosystem functioning, and their related planetary and regional boundaries, can be integrated with available AESA methods to support decision-making towards managing production and consumption activities within all planetary boundaries.

5.01.P-Mo404 Land-Use-Related Biodiversity Loss Embedded in Global Mining Supply Chains
*Yue Yu[1], **Shuntian Wang**[1], Livia Cabernard[2] and Stephan Pfister[1], (1)ETH Zurich, Switzerland, (2)Technical University Munich, Germany*
Global mining activities have undergone substantial expansion and intensification due to the escalating demand for minerals and metals, spurred by digitalization, infrastructure growth, and renewable energy transition. Such developments push Earth s system closer to the limit of the triple planetary crisis, particularly in biodiversity loss, including habitat destruction and landscape fragmentation. To mitigate mining-related biodiversity loss and align mining resource use with planetary boundaries, a spatially explicit assessment framework coupled with comprehensive supply chain analysis is urgently needed. Here, we first derived a land use and land cover map that categorizes mining land use separately. Subsequently, absolute biodiversity loss from global mining was quantified by assessing local biodiversity intactness loss and global biodiversity importance at high spatial resolutions (10-arc-seconds and 30-arc-seconds). These biodiversity impacts were aggregated at the country level and allocated to specific mining commodities based on the monetary values of the respective extracted metal quantities in each country. Furthermore, the Resolved EXIOBASE dataset was used to link mining-related biodiversity loss from production to consumption perspectives. Our findings suggest that global mining leads to a 0.034 % global potentially disappeared fraction, accounting for nearly 70% of the planetary boundary budget for biodiversity loss. Biodiversity loss hotpots, including Indonesia, New Caledonia, Australia, Brazil, and Peru, account for 57% of the total impact. 82% of mining-related biodiversity impacts stem from extracting coal, precious metals, nickel, iron, and copper. Due to international trade, 77% of the mining-related biodiversity footprint is induced in countries other than final consumption. 58% of mining-related biodiversity footprint is driven by demand from China, Europe, Japan, and the USA, particularly in construction, services, machinery, and electronics. This analysis provides a holistic understanding of the absolute mining s biodiversity footprint and identifies levers to mitigate the adverse impacts. Further research is needed to standardize the mapping of mining land use, fill the data gap of mining production, and refine the assessment by increasing the taxonomic diversity and geographic representativeness, providing time series, and quantifying uncertainties arising from species ranges and taxonomic representativeness, among others.

5.01.P-Mo405 Just Allocation Principles for the Absolute Sustainability of European Battery Manufacturing
***Maeva Lavigne Philippot** and Maarten Messagie, Vrije Universiteit Brussel, Belgium*
The absolute sustainability of a sector based on the planetary boundary framework requires defining its share of safe operating space (SoSOS) which greatly influences the results. Current studies at country, regional or sector level apply ethical norms such as egalitarian, utilitarian, prioritarian, and inegalitarian principles - to calculate this SoSOS, often combining multiple approaches without justification. If the SoSOS definition is meant to be just, it is important to recognize varying definitions of justice. Distributive justice includes not only egalitarian and prioritarian principles but also sufficientarian, principles of merit and limitarian principles. Furthermore, justice can be intragenerational but also intergenerational and interspecies. This study will calculate several SoSOS for the EU battery sector (consumption and production), while looking for justification to use SoSOS. Challenges arise from social acceptability and data availability.

To define a European SoSOS, various combinations of principles will be explored. The egalitarian perspective allocates equal SoSOS to all inhabitants of a region, advocating equal access to the ecological space. However, equity not only involves sharing resources, but also sharing rights, responsibilities, and risks. A SoSOS can be calculated for the current population. However, incorporating intergeneration criteria requires integrating future populations, which poses a challenge due to projections.
The utilitarian perspective considers sectoral utility, with economic added value, job creation, and physical output as potential bases. The sector s share in the European final consumption expenditure may also be used.
Under the prioritarian perspective, a right to development can be used based on the human development index. Applying historical emissions to a growing sector like batteries is complex. Priority could also be given to essential sectors such as health, agriculture, education, building, which exact list is to be defined.
In an inegalitarian perspective, the grandfathering approach would be applied, basing SoSOS on current European and sector emissions.
It is recommended to use multiple sharing principles. This study will present a mix of established and innovative sharing principles. Although focused on the battery sector, the resulting SoSOS framework could apply to other sectors and countries, with global and local limits potentially treated differently.

5.01.P-Mo406 Bringing Together Global and Regional Biophysical Limits of the German Bioeconomy and Corresponding Bioeconomy Scenarios Facilitating Absolute Environmental Assessment of the Sector – A Review

***Matthias Welker**, Alberto Bezama and Walther Zeug, Helmholtz-Centre for Environmental Research (UFZ), Department of Bioenergy, Germany*

The concept of bioeconomy oscillates between envisioning a potential high-tech future in which bio-based materials enable additional economic growth, or emphasizes biomass as a necessary means to replace fossil resources in a world characterized by reduced overall consumption. The given research aims to lay the groundwork to subject those visions to a reality check on the basis of Absolute Environmental Sustainability Assessment (AESA).
In this review, the research aims to answer the question: How can global and regional impacts and biophysical limits of bioeconomy scenarios in Germany be quantified?
To answer this question, first, the work aims to review the research landscape for quantifiable biophysical limits, relevant as a sustainability benchmark to the German bioeconomy. While the review will lay an emphasis on the regional explicitness of biophysical limits at different scopes, it will also include examples of downscaled global limits. Second, the author aims to give an overview of established bioeconomy scenarios and modelling efforts. With this it is planned to review which of those fulfill the characteristics, needed for a global or regional AESA of the concept.
The research aims to build the basis for an AESA, as the result will establish an overview of available quantifications of limits and scenarios. Hereby, it takes a novel explicit regional and sectoral focus, advancing the research of AESA and bioeconomy monitoring.

5.01.P-Mo407 Operationalization of the Absolute Environmental Sustainability Assessment for the Safe and Sustainable by Design Framework: An Approach

***Sarah Devecchi**[1], Lisa Pizzol[1], Danail Hristozov[2], Alex Zabeo[1] and Elena Semenzin[3], (1)GreenDecision S.r.l., Italy, (2)Emerge Ltd, Bulgaria, (3)Ca' Foscari University of Venice, Italy*

The Joint Research Centre's (JRC) Framework on Safe and Sustainable by Design (SSbD) chemicals and materials has relied, up to now, on traditional comparative Life Cycle Assessment (LCA) methods for evaluating environmental sustainability. However, the ever-growing global economy is pushing to the limit the earth systems, for which a new generation of absolute environmental sustainability assessment (AESA) is being developed, by integrating the planetary boundaries (PBs) framework in the LCA. LCA-based AESA has, until now, been applied primarily to established chemicals with known production processes and market shares. However, when conducting a sustainability assessment in the context of SSbD, it is essential to account for ongoing testing and for the iterative development process of new materials. The link between AESA and the SSbD framework is explicit, but still lacks an operational perspective. Indeed, the actual global pressure of chemicals is still unknown, while, at the same time, the pace of production exceeds the capacity to test their environmental effects prior to the release on the market. Moreover, AESA has not yet incorporated the boundary for Novel Entities (NEs) in any evaluation. Since SSbD chemicals and materials may qualify as novel entities both in a geological context and within the current market, operationalizing NEs assessment is crucial to integrate an absolute sustainability perspective in this context. For these reasons, within the EU SunRise and BioSusTex projects, a multiple step approach is being developed, to adapt the absolute assessment to the stages of development of SSbD chemicals / materials. Chemicals pressure on the environment is being investigated for a specific set of materials through assessment in a lifecycle perspective. Safety testing, persistence analysis, and supply chain monitoring are the key aspects assessed to ensure respect for the boundary s threshold. On a bigger scale, the market sector for which the innovative chemical/material is designed is assessed against the planetary boundaries in the first development phases, when data availability is low. This is followed by an assessment of the product incorporating the innovation, aligning with a phase where more data can be collected. The results, in LCA fashion, would support the optimization processes during the design, allowing monitoring the transgression of the PBs and pointing out the hotspots of concern.

Disclaimer/Disclosure: This work is carried out under the SunRise project grant agreement No 101137324 and the BioSusTex project grant agreement No 101135372

5.01.P-Mo408 Translating Planetary Boundaries into Material-Level Life Cycle Assessments
Xue Sun[1]*, Stephan Pfister*[2] *and Roland Hischier*[1]*, (1)EMPA - Swiss Federal Laboratories for Materials Science and Technology, Switzerland, (2)ETH Zurich, Switzerland*
As global environmental degradation accelerates, the Planetary Boundary (PB) framework provides a critical lens to evaluate social activities in relation to the ecological limits. At a material level, integrating the PB framework into Life Cycle Assessment (LCA) for an absolute assessment remains challenging, particularly for advanced materials highlighted in the EU CHIASMA project.
This contribution introduces a novel framework that translates global PBs into actionable, material-level LCA (PB-LCA) using a Multi-Layer Network Analysis and the Material Boundary Availability (MBA) method. Our network comprises three layers: key materials, life cycle stages, and nine PB dimensions. Analyzing network links, centrality, and edge weights identifies materials and life cycle stages that significantly influence the various PBs. By further evaluating each material s contributions to specific PB dimensions and defining maximum sustainable consumption levels across material consumption sectors, lifecycles, and use patterns, the MBA method quantitively allocates safe operating space for materials within PBs. For instance, we allocate a portion of global CO2 boundaries to a specific material sector based on its share of production, calculate its environmental impacts, and incrementally scale up until a boundary is violated at a chosen probability, yielding the maximum allowable volume for that sector. We provide practical insights to pinpoint materials most at risk of exceeding PBs and highlight them with visualization tools like heatmaps, enhancing data specificity and informing regulatory and industry practices for targeted interventions. Scenario analysis assesses the framework s robustness under these interventions to different degrees, addressing future uncertainties in technological developments, policy shifts, and circular economy practices. By combining the grandfathering allocation based on established shares and a sufficiency allocation rooted in basic needs fulfillment, the developed framework helps identifying a pathway from historical stability to a transitional, fair and sustainable future within Earth s ecological limits.
Finally, we present ideas for integrating PB-LCA into the Safe and Sustainable by Design (SSbD) framework. By developing material-level sustainability standards in future steps, our work would contribute valuable insights for globally guidelines and enhances datasets with key case studies from the CHIASMA framework.

5.01.P-Mo409 A Boundary for Global Abiotic Resource Use: Constraints from Limited Regional Water Availability
Kamrul Islam[1]*, Keitaro Maeno*[1]*, Ryosuke Yokoi*[1]*, Damien Giurco*[2]*, Shigemi Kagawa*[3]*, Shinsuke Murakami*[4] *and Masaharu Motoshita*[1]*, (1)National Institute of Advanced Industrial Science and Technology, Japan, (2)University of Technology Sydney, Australia, (3)Kyushu University, Japan, (4)The University of Tokyo, Japan*
Abiotic resource production is essential for global economic development and the transition to low-carbon technologies but comes with significant environmental consequences, particularly through the use of regionally available water. This study examines the global production capacity of 32 abiotic resources, considering regional water availability as a key constraint. Our analysis reveals that current abiotic resource production exceeds water availability, with copper production in 2010 surpassing local water capacity by 37%. Relocating production to areas with lower water stress could alleviate these exceedances; however, economic factors often limit the feasibility of such shifts. Additionally, projected future demand for abiotic resources is expected to increase water consumption significantly. Incorporating water resource constraints into production strategies is crucial to ensuring sustainable resource management.

5.01.P-Mo410 Using Absolute Limits at Regional Level: Is Flanders Living Within its Fair Share of the Planetary Boundaries?

***Karolien Peeters**, An Vercalsteren and Maarten Christis, Flemish Institute for Technological Research (VITO), Belgium*

Flanders, a region in Belgium, faces numerous challenges in maintaining a high-quality living environment. The Planetary Boundary (PB) framework is a widely recognised tool for assessing the stability of Earth System (ES) processes. This study explores the applicability of the PB framework in Flanders policy context, focusing on its potential to monitor the region s contributions to global and local environmental impacts. The research question is: Is Flanders living within its fair share of the planetary boundaries?

Applying the PBs concept at a sub-global scale requires translating globally defined limits to a regional context, a process that involves normative choices. Downscaling of the PBs to delineate the safe operating space for Flanders was done by applying the allocation principles Equality, Needs, Right to development, Sovereignty, Capability as proposed by EEA/FOEN. Each PB is assessed through control variables, yet these often differ from the indicators currently used by Flanders. The study involved the identification of the most appropriate control variables or proxy indicators for Flanders across all PBs.

The Flemish environmentally extended multi-region input-output (EE MR-IO) model was used to calculate footprint indicators for Flanders, where not yet available. By comparing these footprints with the safe operating space for Flanders, the study determined whether Flanders exceeds its fair share of the PBs. This analysis was done for those PBs for which regional data were available or could be easily calculated, being climate change, biosphere integrity, land system change, biogeochemical flows and freshwater use.

The study reveals that Flanders exceeds its safe share for four out of five ES processes, with freshwater use being the only exception. However, further research is necessary to define the best suitable proxy indicators to monitor PBs in Flanders, especially to address specific regional environmental issues. The study incorporated elements of Life Cycle Assessment (LCA) to define the boundaries for climate change and biosphere integrity. However, the overall contribution of LCA remained limited. Conversely, useful insights were gained for applying absolute sustainability assessment within LCA. EE MR-IO models demonstrated potential for calculating sectoral contributions to ES process, providing a basis for setting sector-specific targets.

5.01.P-Mo411 Challenges in Aligning the European Chemical Industry with Planetary Boundaries

***Carlos Pozo**[1] and Irene Barnosell[2], (1)Rovira i Virgili University (URV), Tarragona, Spain, (2)LEQUiA, Institute of the Environment, University of Girona, Spain*

The European chemical industry plays a critical role in the region's economy, producing essential compounds for numerous sectors. However, its environmental footprint is also substantial, with high energy consumption, significant greenhouse gas emissions, and the release of harmful chemicals. Previous research on the environmental performance of the sector is limited to specific processes, lacking a comprehensive sector-wide perspective. To address this gap, here, we evaluate the sector's environmental performance and compare it against the planetary boundaries (PB), which defines the ecological limits for human activities to operate safely. This allows us to ascertain if the sector is sustainable and, if not, identify key areas of transgression.

We model the sector based on the 19 highest-volume chemicals, accounting for 80% of the industry s energy consumption and 75% of its greenhouse gas emissions. This highlights their critical role in both production volume and environmental impact. Given that each of these chemicals can be manufactured through multiple processes, our analysis incorporates data from 32 processes across 23 datasets, sourced from the ecoinvent 3.5 database. To avoid double counting impacts, we explore the links between these 23 activities and adjust production volumes accordingly.

Our findings reveal that the European chemical industry significantly exceeds multiple PBs, particularly climate change, ocean acidification, and biosphere integrity. The industry's contribution to atmospheric CO2 concentration and energy imbalance at the top of the atmosphere exceeds safe levels by 15 and 16 times, respectively, while impacts on ocean acidification are 6 times greater than acceptable. The biosphere integrity boundary, assessed here via functional diversity, is also slightly transgressed (3%). Five high-volume chemicals ammonia, polypropylene, high-density polyethylene, styrene, and benzene are responsible for 50% of the sector's overall environmental burden across all PBs.

We also explore various mitigation pathways, including the deployment of carbon capture and storage (CCS) technologies, the use of renewable energy, and green hydrogen. Our results indicate that CCS could enable the sector to meet all PBs concurrently, yet burden-shifting remains a concern. Hence, these technological solutions must be implemented in conjunction with broader systemic changes, including policy interventions and cross-sector collaboration.

5.01.P-Mo412 Combining Life Cycle Assessment and Planetary Boundaries in the Textile Fiber Sector: Absolute Environmental Sustainability Assessment of Regenerated Cellulosic Fibers

***Juulia Suuronen**, Mirja Mikkila and Elias Hurmekoski, (1)University of Helsinki, Finland,*

The textile fiber sector has been growing for decades through the growth of synthetic fibers driven by, for instance, fast-fashion and increased welfare. The growth has fueled major environmental impacts. Wood-based regenerated cellulosic fibers (RCFs) may help in reducing the environmental impacts, though they may not be perfect substitutes for the established fiber types.

Life Cycle Assessment (LCA) is a standardized method to evaluate the environmental impacts of products, and it has been used to assess the environmental impacts of numerous products, including textile fibers. One of the shortcomings of LCA is its relativity: an LCA analysis can provide insights on whether a product causes more environmental burden than another product, but it cannot answer whether a product itself can be considered sustainable in the face of environmental crises. The Planetary Boundary framework provides a risk analysis for nine areas of Earth systems and the point at which humans operate currently relative to these areas and their safe operating spaces. In recent years, Absolute Environmental Sustainability Assessment (AESA) has been receiving growing interest as it aims to overcome the shortcoming of LCA by combining LCA with the PB framework to evaluate if a product can be considered sustainable in absolute terms.

This study will implement the AESA approach of combining LCA and the PBs to evaluate the absolute sustainability of the most established RCFs. The objectives are i) to allocate PBs for the RCFs with alternative approaches, ii) to calculate the life cycle impacts of the most common RCFs, and iii) to compare the LCA results to the defined PBs to examine the overall sustainability of the RCFs. One of the key challenges is to determine the planetary boundaries for RCFs, in which the choice of sharing principles is likely to influence the results. Therefore, sensitivity analysis will be a key part of the analysis.

This study will contribute to the existing AESA literature through a case study on textile fibers. It contributes further to the assessment of sustainability of wood uses, as wood-based textile markets are expected to grow in the future in the effort to reduce the textile sector s environmental impacts by RCFs substituting for the established fibers with greater environmental burden.

5.01.P-Mo413 Planetary Boundaries and Absolute Sustainability in LCA – Past, Present and Future

*Efstathios Reppas Chrysovitsinos[1], Sarah Devecchi[2], Anna Lia Tromer Dragsdahl[3], Stig Olsen[3], Lisa Pizzol[4], Elena Semenzin[2] and **Tomas Vilhelm Rydberg**[1], (1)Swedish Environmental Research Institute (IVL), Sweden, (2)Ca'Foscari University of Venice, Italy, (3)DTU, Denmark, (4)Green Decision, Italy*

Since the introduction of the Planetary boundaries concept in 2009 there has been an increasing interest in this concept which in its approach is based on a notion of finding an absolute threshold for sustainability on a global level. In line with this concept an adaptation was made to the LCA context by Bjorn et al, essentially redefining the planetary boundaries to LCA by cakculating the threshold limits expressed in impact indicators as used in the LCA community.

With this study, the authors wanted to review the use of the planetary boundaries and absolute sustainability concepts in the LCA history as well as currently and provide a perspective on the anticipated use looking forward. The work carried out here has worked its way back through surveying both scientific and grey literature to find studies applying weighting of this third type and illustrate how they relate to the planetary boundaries, and some initial findings are presented.

The earliest method found to apply a distance to target approach for assessing LCA impacts was the eco-scarcity method. Later in the 1990-s, two approaches were developed independently in the Netherlands and the Nordic countries, the Eco-indicator 95 method and the ETlong method. Initial observationsa are that a boundary for absolute assessment is a very dependent on the criterium set for establishing the boundary. A further observation is that for many impact categories, although the boundaries are depending on the geographical location, a criterium can be applied by extrapolation or similar approach. But the establishing of the criterium and thus the boundary will ultimately be done by a partly subjective decision. Work will continue towards a broader understanding of the prospects of absolute sustainability in LCA.

5.01.P-Mo414 A Step Beyond Life Cycle Thinking: Linking Supply Chain With Planetary Boundaries

Sara Toniolo *and Ivan Russo, University of Verona, Department of Management, Italy*

The sustainability of supply chain has emerged as a new stream for operations, which aims to actively create positive effects by designing supply chains that reduce the consumption of natural resources and generate social capital, also embracing the life cycle thinking. Going beyond this perspective means to acknowledge that mutual interactions exist along a supply chain and at different levels, interpretating it as a complex adaptative networks with interconnections with the natural system. This research proposes an analysis of the current level of interaction between supply chain and planetary boundaries, to identify areas for improvement and actions to be taken.
The intent of this research is to give an answer to the following research questions (RQ):
RQ1: How is the concept of planetary boundaries incorporated along a supply chain?
RQ2: How can the supply chain view and the life cycle perspective interact within the planetary boundaries?
The research is based on a systematic literature review and applies a life cycle thinking perspective, with the intent to consider the main environmental aspects associated with a supply chain.
A research by keywords was performed in ISI Web of Knowledge database in October 2024. The final combination of keywords was ("planetary boundaries OR planetary boundary) AND supply chain , leading to 33 articles. Then, based on a relevance analysis, 21 articles were finally selected. They were analyzed separately to identify how planetary boundaries can be incorporated along a supply chain, to address RQ1. Successively, they were crossed to identify how and if the life cycle perspective is applied or discussed, giving an answer to RQ2.
This research contributes to a comprehensive understanding of how to guide the work of supply chains within the planetary boundaries, showing how companiens can operate also through the life cycle thinking. The research highlights the importance of measuring impact and performance outcomes to achieve sustainable operations and provides insights to assess and improve the sustainability level along a supply chain.

5.02 Dimensions and Challenges of Life Cycle Assessment to Steer Innovation and Competiveness of Safe and Sustainable Chemicals and Materials

5.02.P-Mo416 Estimating the Carbon Footprint of 130,000 Organic Chemicals with FineChem2

Dachuan Zhang[1]*, Zhanyun Wang*[2]*, Christopher Oberschelp*[1] *and Stefanie Hellweg*[1]*, (1)ETH Zurich, Switzerland, (2)EMPA - Swiss Federal Laboratories for Materials Science and Technology, Switzerland*

Accurately understanding the product carbon footprints (PCFs) of chemicals is essential for promoting the sustainable transition of the chemical industry and its dependent sectors. In this study, we identified the limitations of traditional indicators such as molecular weight and market price for estimating PCFs, particularly for complex fine chemicals. To address these limitations, we developed an improved machine learning-based model with enhanced accuracy, expanded applicability, and robust uncertainty measures. Applying this approach, we analyzed PCF data for over 130,000 chemicals registered across 27 national inventories. Additionally, our analysis revealed that newly registered chemicals typically exhibit higher PCFs compared to existing ones, highlighting the urgent need for sustainable design guidelines. Furthermore, we demonstrated that molecular frameworks significantly impact PCFs, with more ring structures often correlating with higher carbon emissions. We also found that chemical additives in plastics contribute substantially to PCFs, underscoring the risk of biased conclusions when these factors are overlooked. We anticipate this study will support more informed decision-making for chemical producers, consumers, and policymakers aiming to design and use more sustainable chemicals.

Disclaimer/Disclosure: This publication was created as part of NCCR Catalysis (grant number 180544), a National Centre of Competence in Research funded by the Swiss National Science Foundation.

5.02.P-Mo418 Integrating Risk Assessment and Life Cycle Assessment Methods in a Safe and Sustainable by Design Context

***Neeraj Shandilya**, Lia de Simon, Tom Ligthart and Wouter Fransman, TNO, Netherlands*
It is crucial to assess the safety and sustainability of new chemicals or materials early in the design phase to ensure responsible development. The Safe and Sustainable by Design (SSbD) approach offers a comprehensive way to evaluate safety and sustainability from the outset, using human health risk assessment (HHRA) and life cycle assessment (LCA) to ensure long-term viability.

This work highlights the strengths and weaknesses of performing HHRA and LCA separately and demonstrates how to overcome these challenges in an SSbD context. Using perovskite-based solar cells (PSC) as a case study, we show the proof of concept. PSC offer high efficiency and low production costs but face issues with stability and material toxicity, which raise safety and sustainability concerns for their commercialization. The focus here is on demonstrating the integrated SSbD approach to support decision-making, rather than providing a detailed assessment of PSC safety and sustainability.

We demonstrated that without such an integrated approach, the comparative LCA does not cover the (absolute) human health risks associated with substances emission into the (work) environment. For the case of PSC, LCA showed human toxicity midpoint to be far less impactful than other midpoint categories (e.g. global warming, fine particulate matter formation) which might lead to its overlooking during decision making. On the other hand, integrating HHRA with LCA ensures a proactive risk aware approach that determines, in advance, the risks associated with human toxicity and calls for necessary chemical substitution during product design. Moreover, the integrated approach provides the necessary characterisation factors for an accurate LCA modelling in the relative toxicity impact categories. Furthermore, the human toxicity midpoint within LCA only accounts for the general population exposure and excludes specific sub-groups like workers and consumers who could be more directly in contact with the toxic (volatile) substances. Through the integrated approach, we could account for a more detailed exposure assessment in such specific sub-groups.

Therefore, such an integrated HHRA-LCA approach can be beneficial for a holistic and yet meticulous assessment of a novel product for decision making in an SSbD context.

5.02.P-Mo423 Decision Support in Safe and Sustainable by Design: A Case Study in the Energy Storage Sector

*Clemens Wolf[1], Julia Wenger[2], Andrea Weiner[3], Anna Spindlegger[4], Aleksander Jandric[4], Matiss Reinfelds[1], Andoni Cruz[3], Florian Part[4], Stefan Spirk[5] and **Claudia Mair-Bauernfeind**[6], (1)BioNanoNet Forschungsgesellschaft mbH, Austria, (2) University of Graz; TU Graz, Austria, (3)Biobide BBD Biophenix SLU, Spain, (4) BOKU University, Austria, (5) Graz University of Technology, Austria, (6) University of Graz, Austria*
Stationary energy storage systems (ESS) are essential for stabilizing grids and ensuring reliable energy supply during the renewable energy transition. Redox flow batteries, as a promising ESS technology, offer scalability and long lifespans, but uncertainties about their safety and sustainability across the value chain necessitate further evaluation to address stakeholder concerns and guide ESS development. In this context, the safe and sustainable by design (SSbD) framework aims to minimize safety and sustainability risks in new materials through a holistic, life-cycle approach. However, uncertainties remain about its practical application to specific products and how to present results clearly to support decision-making at various levels. This study addresses these gaps by exploring the SSbD framework as a decision support tool at two levels: design and technology selection. An organic active element for redox flow batteries was chosen as the focus of the investigation. The assessments conducted (i.e., toxicity, environmental, social, economic, circularity and technical performance assessment) are based on the JRC SSbD framework, extended with use case-specific performance indicators. In each assessment step, several different indicators are evaluated (e.g., 16 impact categories for the life cycle assessment step), resulting in more than 30 indicators overall. Based on these results, a SSbD Matrix will be developed depicting the results in a heat map for the two decision-making levels (design and selection). To refine and validate the SSbD framework, a three-step approach for stakeholder involvement is planned: 1) A workshop with design engineers for the design support tool. 2) A workshop to discuss applicability with the SSbD community. 3) A stakeholder workshop for the selection support framework, with potential consumers (e.g., participants from the energy sector). The SSbD matrix, enabled a comprehensive comparison of electrolytes and batteries by integrating safety, sustainability, and technical performance indicators. It also serves as a stakeholder engagement tool, visualizing trade-offs and performance bottlenecks. By mapping lifecycle hotspots, the matrix provides targeted recommendations for design improvements, material substitution, supply chain management, and recycling strategies. Future research should focus on systematically weighting indicators and refining the matrix to enhance its precision and broader applicability.

5.02.T-01 In Vitro & In Silico-Derived Effect Factors for USEtox: A Framework for Non-Animal Toxicity Characterization in Life Cycle Assessment

Marc Majo[1]*, Ishita Virmani*[2]*, Xue Sun*[1]*, Martin Paparella*[2] *and Roland Hischier*[1]*, (1)EMPA - Swiss Federal Laboratories for Materials Science and Technology, Switzerland, (2)Medical University of Innsbruck, Austria*

The Horizon Europe project CHIASMA aligns with the European Commission's Safe and Sustainable by Design (SSbD) framework, aiming to integrate New Approach Methodologies (NAMs) into a robust system for human and environmental safety evaluations. CHIASMA focuses on incorporating in vitro and in silico data into the USEtox model to improve life cycle impact assessments (LCIA) by reducing reliance on animal testing.

Within CHIASMA, a stepwise approach advances Next Generation Safety Assessment (NGSA), refining USEtox for human and environmental toxicity characterization. This involves using physiologically-based kinetic (PBK) modeling and Quantitative Structure-Activity Relationships (QSAR) to estimate human-relevant doses, aligning with SSbD goals. It also incorporates the planetary boundary framework to evaluate absolute environmental sustainability.

The adaptation of USEtox to integrate in vitro and in silico-derived human toxicity effect factors (EFs) involves recalculating EFs based on non-animal data. CHIASMA uses QSAR and PBK models to estimate human-relevant doses from in vitro results. This process supports the operationalization of SSbD and aligns with LCIA goals.

Steps include:

Data Collection: Gather in vitro data on human toxicity endpoints and validate with in vivo data. QSAR models predict toxicity and benchmark doses for chemical analogues.

Benchmark Dose (BMD) Calculation: Adjust in vitro dosimetry to surface-area-based BMDs for standard comparisons with in vivo benchmarks.

Extrapolation Factors: Derive in vitro-to-in vivo extrapolation factors using the parallelogram approach and validate with QSAR/PBK models. Convert in vitro concentrations to human-relevant doses using PBK models.

EF Development: Integrate PBK-adjusted BMDs to calculate normalized human toxicity EFs consistent with USEtox standards.

Uncertainty Management: Use Monte Carlo simulations and dispersion factors to account for variability and enhance EF reliability.

The integration of these methods improves transparency and reliability. Adjustments are made for variability and uncertainty using Monte Carlo simulations, ensuring robust EF outputs. By operationalizing SSbD principles, CHIASMA provides a user-friendly framework for sustainable and safe chemical assessments.

This transformative approach demonstrates the feasibility of using non-animal data for regulatory applications while aligning safety evaluations with ecological and human health goals.

5.02.T-02 In-Silico Screening of New Chemicals for SSbD: Coupling Data-Driven Approaches and LCA

Gustavo Larrea-Gallegos and ***Antonino Marvuglia****, Luxembourg Institute of Science and Technology (LIST), Luxembourg*

With the introduction of the "Safe and Sustainable-by-Design" (SSbD) framework, the interest in practical applications of SSbD for new products has increased among policy, academic, and industrial players around the EU. During the development of new materials and products, the lack of information about impact pathways poses significant challenges. To ameliorate this problem, machine learning (ML) approaches can be used to screen the LCA impacts of new chemicals and materials.

In this study we applied an ML-based predictive model that can be used to estimate the impact of in-silico models of new chemicals. We selected chemicals included in the ecoinvent 3.10 database that could be associated with a Chemical Abstracts Service (CAS) number as training data. For them, we calculated their life cycle impact using the Environment Footprint (EF) method (19 impacts). The training features were physical-chemical descriptors generated using the chemicals' SMILE representation and the RDKit python toolkit. This finally yielded a data set consisting of 724 chemicals and ca. 200 descriptors. The model was trained following a conventional ML pipeline using the XGBoost algorithm (data curation, train/test split, hyperparameters search and cross-validation). We used the coefficient of determination

(R2) as performance metric, and we developed surrogate models to analyze feature importance and increase the explainability of the model.

The performance of our models (R2) ranged from 0.58 to 0.82 (Climate Change - biogenic and Climate Change, respectively) depending on the impact. For some impacts (e.g., Climate Change), our results matched and even outperformed other models reported in the literature. Our model can be used to provide fast and cost-effective estimations of LCA impacts of in-silico models of chemicals in the context of the SSbD framework. By using ML algorithms, we provided an end-to-end solution that can facilitate the screening of impacts when designing new chemicals. The novelty of our study relies on the use of a very recent life-cycle database and the consideration of the EF method for calculating impacts. Moreover, we also provided surrogate models to facilitate the understanding and reliability of our predictions. Finally, future steps will involve building a prospective screening LCA model by following the same ML pipeline, but incorporating prospective background inventories, and additional expert knowledge to describe the foreground system.

Disclaimer/Disclosure: This study has received funding from the European Union s Horizon Europe Research and Innovation programme under grant agreement No.101137809 (project Provision of Integrated Computational Approaches for Addressing New Markets Goals for the Introduction of Safe-and-Sustainable-by-Design Chemicals and Materials - PINK).

5.02.T-03 Integrated SSbD Approach to Simulating the Sustainability of Lubricants: Challenges and Insights

Jonas Hoffmann *and Andreas Ciroth, GreenDelta GmbH, Germany*

The global drive to reduce carbon emissions highlights the importance of friction and wear management in reducing CO? emissions and global energy consumption. Lubricants are vital for the efficiency and durability of machinery, especially in low-carbon sectors like e-mobility and renewable energy. However, many conventional lubricants are environmentally harmful, necessitating the design of sustainable, non-toxic alternatives. The European Commission s Safe-and-Sustainable by Design (SSbD) framework aims to guide this process. Initial case studies show that SSbD assessment for marketed products can be time and cost-intensive.

The SiToLub project aims to address these challenges by simulating all SSbD dimensions - such as toxicology, biodegradability, and performance - into life cycle assessments (LCAs) of lubricants. This study compares a soybean-based bio-lubricant with a conventional petroleum-based lubricant using data from literature and a stoichiometric approach to model the bio-lubricant s life cycle. The cradle-to-gate impact assessment reveals that the bio-based lubricant has higher eutrophication, ecotoxicity, and toxicity impacts due to soybean cultivation, as expected. However, the fossil resource use and toxicity impacts were comparable, suggesting biases in comparing optimized petroleum-based processes with lab-scale bio-based ones.

This mismatch in Technology Readiness Levels (TRLs) poses a challenge in applying the SSbD framework effectively. The hierarchical approach used in low TRL development fails to capture the full sustainability of lubricants, particularly performance variations and end-of-life (EoL) scenarios. To improve this, the study incorporates EoL parameters like recyclability and recycling content into the life cycle model, reducing environmental impacts across relevant categories. Additionally, integrating QSAR methods for toxicology and biodegradability with reactive molecular dynamics simulations for performance offers a more comprehensive sustainability assessment.

Our findings highlight the limitations of the SSbD framework when applied to low TRL bio-based lubricants. A fully integrated SSbD approach, considering the entire life cycle and intrinsic properties like toxicity, performance, and biodegradability, is necessary for accurate sustainability assessments. Software-based solutions provide an efficient and cost-effective way to conduct these evaluations, addressing challenges in benchmarking new technologies.

5.02.T-04 Ecological Sustainability Assessment of Battery Energy Storage Systems: From Second-life to End-of-Life

Anna Spindlegger[1]*, Aleksander Jandric*[1]*, Ricardo Gabbay De Souza*[2]*, Stefanie Prenner*[3] *and Florian Part*[1]*, (1)Institute of Waste Management and Circularity, BOKU University, Austria, (2) Technical University of Denmark, Denmark, (3)Brimatech Services GmbH, Austria*

The increasing demand for electric vehicles and battery energy storage systems (BESS) is driving a surge in the number of end-of-life lithium-ion batteries, necessitating effective end-of-life management strategies, such as repurposing and recycling. However, the implementation of these strategies faces challenges due to the diversity of battery designs, highlighting the importance of circular battery design principles. This study aims to assess the environmental impacts of different repurposing and recycling strategies for second-life BESS, providing insights that can guide improvements in the (re)design phase of lithium-ion batteries. A life cycle assessment was conducted on a second-life BESS, aligning with step 4 of the Safe and Sustainable by Design framework. Four repurposing cases were evaluated, focusing on the reuse of battery components in the second-life, and three cell recycling routes (pyrometallurgical, hydrometallurgical and advanced hydrometallurgical recycling). These results were then compared to a new BESS to determine environmental benefits or drawbacks of applying repurposed lithium-ion batteries. The results revealed a superior environmental performance of second-life BESS compared to new systems in four out of five analysed impact categories. The lowest impacts were identified when both the module casing and the battery management system are reused, while the highest impacts were observed when both components are replaced. The recycling phase demonstrated significant impact reductions, particularly in metal depletion and freshwater ecotoxicity. However, the reuse of the BMS significantly diminished these reductions for freshwater ecotoxicity, leading to environmental drawbacks of the repurposed system. Hydrometallurgical recycling methods achieved slightly higher mitigations due to the recovery of additional materials compared to pyrometallurgical recycling. This study underscores the potential of second-life BESS to reduce carbon emissions and decrease resource extraction. By evaluating various repurposing and recycling strategies, it highlights effective approaches to improve the environmental performance of second-life BESS. The findings emphasize the importance of considering end-of-life options in the battery design phase. Design for circularity can contribute to more efficient material recovery and improve the reusability of battery components, thereby improving the overall sustainability of battery energy storage systems.

5.02.P Dimensions and Challenges of Life Cycle Assessment to Steer Innovation and Competiveness of Safe and Sustainable Chemicals and Materials

5.02.P-Mo415 SaSo-HS tool: Leveraging Safety and Social Impact in the Safe and Sustainable by Design (SSbD) Framework

***Antonio Nogueira**, Beatriz Loureiro, Maria Pereira, Pablo Vicos and German Ferreira, HOLOSS, Portugal*

The European Commission has launched the Safe and Sustainable by Design (SSbD) framework to promote innovation towards safer and more sustainable chemicals, materials, and products. The SSbD framework includes five key steps that integrate risk and sustainability assessments, with Life Cycle Assessment (LCA) covering environmental aspects. However, other sustainability dimensions such as economic and social are not yet fully developed or consistently applied. The social Life Cycle Assessment (s-LCA), which aims to operationalise social aspects, still faces significant challenges in terms of data granularity, availability, and applicability.

To address these limitations, this study introduces the SaSo-HS tool, developed by HOLOSS, to bridge the gap between safety and social assessments in the SSbD framework. The methodology includes conducting a comprehensive literature review to identify relevant areas that connect safety and social dimensions, designing a questionnaire to assess impacts in these areas, and developing a scoring system to transform qualitative data into semi-quantitative information. The SaSo-HS tool was iteratively refined to ensure it is comprehensive, user-friendly, and capable of providing holistic evaluations. It enables innovators to predict the impacts of their innovations across public health, urban health, vulnerable populations, toxicology regulations, social justice, and consumer trust.

The SaSo-HS tool provides a mechanism for innovators to assess the societal and safety impacts of new technologies in a structured and consistent manner. Future validation in relevant fields is essential to enhance the robustness of the tool. Expanding the survey scope to include new areas and additional questions will also improve its comprehensiveness, helping to align innovations with the Sustainable Development Goals (SDGs) set by the United Nations. Ultimately, this integration of safety and social assessments seeks to support a more systemic, responsible, and sustainable development process, ensuring that new innovations benefit society while mitigating risks.

5.02.P-Mo416 Estimating the Carbon Footprint of 130,000 Organic Chemicals with FineChem2

Dachuan Zhang[1]*, Zhanyun Wang*[2]*, Christopher Oberschelp*[1] *and Stefanie Hellweg*[1]*, (1)ETH Zurich, Switzerland, (2)EMPA - Swiss Federal Laboratories for Materials Science and Technology, Switzerland*

Accurately understanding the product carbon footprints (PCFs) of chemicals is essential for promoting the sustainable transition of the chemical industry and its dependent sectors. In this study, we identified the limitations of traditional indicators such as molecular weight and market price for estimating PCFs, particularly for complex fine chemicals. To address these limitations, we developed an improved machine learning-based model with enhanced accuracy, expanded applicability, and robust uncertainty measures. Applying this approach, we analyzed PCF data for over 130,000 chemicals registered across 27 national inventories. Additionally, our analysis revealed that newly registered chemicals typically exhibit higher PCFs compared to existing ones, highlighting the urgent need for sustainable design guidelines. Furthermore, we demonstrated that molecular frameworks significantly impact PCFs, with more ring structures often correlating with higher carbon emissions. We also found that chemical additives in plastics contribute substantially to PCFs, underscoring the risk of biased conclusions when these factors are overlooked. We anticipate this study will support more informed decision-making for chemical producers, consumers, and policymakers aiming to design and use more sustainable chemicals.

5.02.P-Mo417 A Qualitative Social Life Cycle Assessment Approach for Early-Stage Safe and Sustainable by Design (SSbD) Projects

Daniela Groiss-Fuertner*, Andreas Barth and Franziska Hesser, Wood K plus, Austria*

Social Life Cycle Assessment (SLCA) is a key part of the Safe and Sustainable by Design (SSbD) framework, which evaluates social and socio-economic impacts. SLCA assesses factors like geopolitical conditions, industry sectors, cultural context, and individual perceptions. Early-stage material and value chain development (low Technology Readiness Levels, TRL) face challenges, such as uncertainties about stakeholders, production locations, and materials. In such stages, literature reviews are often used to understand potential social impacts, but specific knowledge on new value chains is limited. Thus, incorporating stakeholder perspectives is essential. The BIO-SUSHY case study, focused on developing innovative coatings for water- and oil-repellent applications aligned with the EU's chemical strategy, introduces a qualitative approach to address SLCA challenges in early stages. The goal is to identify social issues early in product development and provide guidance on improving social sustainability. SLCA follows the principles of environmental Life Cycle Assessment (LCA) with four steps: goal and scope definition, inventory, impact assessment, and interpretation. In the goal and scope phase, relevant impact categories are defined for specific stakeholders. SLCA complements environmental LCA by assessing potential social impacts across the product life cycle, identifying social hotspots along the value chain. Stakeholder involvement is highly recommended, and the BIO-SUSHY study introduces guidelines for qualitative expert interviews to facilitate this engagement at early TRL stages. Choosing the right interviewees is challenging due to limited knowledge about affected actors, but this can be addressed through in-depth value chain analysis. Integrating SLCA within the SSbD framework requires innovative methods to address knowledge gaps, often using a mix of approaches to prioritize social topics. Method selection depends on the TRL, complexity, and stakeholder knowledge. Engaging stakeholders provides specific perspectives and includes topics related to geographical, sectoral, or process-specific issues. Qualitative interviews offer in-depth insights into stakeholder experiences, preventing over-prioritization of commonly mentioned topics. The case study highlights issues like product quality, price, and technical requirements, with consumer topics also emerging, though often underrepresented in SLCA studies.

5.02.P-Mo418 Integrating Risk Assessment and Life Cycle Assessment Methods in a Safe and Sustainable by Design Context

Neeraj Shandilya*, Lia de Simon, Tom Ligthart and Wouter Fransman, TNO, Netherlands*

It is crucial to assess the safety and sustainability of new chemicals or materials early in the design phase to ensure responsible development. The Safe and Sustainable by Design (SSbD) approach offers a comprehensive way to evaluate safety and sustainability from the outset, using human health risk

assessment (HHRA) and life cycle assessment (LCA) to ensure long-term viability.

This work highlights the strengths and weaknesses of performing HHRA and LCA separately and demonstrates how to overcome these challenges in an SSbD context. Using perovskite-based solar cells (PSC) as a case study, we show the proof of concept. PSC offer high efficiency and low production costs but face issues with stability and material toxicity, which raise safety and sustainability concerns for their commercialization. The focus here is on demonstrating the integrated SSbD approach to support decision-making, rather than providing a detailed assessment of PSC safety and sustainability.

We demonstrated that without such an integrated approach, the comparative LCA does not cover the (absolute) human health risks associated with substances emission into the (work) environment. For the case of PSC, LCA showed human toxicity midpoint to be far less impactful than other midpoint categories (e.g. global warming, fine particulate matter formation) which might lead to its overlooking during decision making. On the other hand, integrating HHRA with LCA ensures a proactive risk aware approach that determines, in advance, the risks associated with human toxicity and calls for necessary chemical substitution during product design. Moreover, the integrated approach provides the necessary characterisation factors for an accurate LCA modelling in the relative toxicity impact categories. Furthermore, the human toxicity midpoint within LCA only accounts for the general population exposure and excludes specific sub-groups like workers and consumers who could be more directly in contact with the toxic (volatile) substances. Through the integrated approach, we could account for a more detailed exposure assessment in such specific sub-groups.

Therefore, such an integrated HHRA-LCA approach can be beneficial for a holistic and yet meticulous assessment of a novel product for decision making in an SSbD context.

5.02.P-Mo419 Integrating the 'Safe and Sustainable-by-Design' Principles with Life Cycle Assessment: A Practical List of Data Requirements and Approach for the Mineral Carbonation of Steel Slags Case Study

***Ponnapat Watjanatepin**[1], Mariana Ochodkova[1], Laura Steinwidder[2], Nina Miladinovic[1], Anthony de Schutter[1], Tom Van Duyse[1], Giuseppe Granata[1], Sara Vicca[2], Tom Van Gerven[1] and Karel Van Acker[1], (1)KU Leuven, Belgium, (2)University of Antwerp, Belgium*

Earlier this year in 2024, the European Commission Joint Research Center published a guidance document for the Safe and Sustainable-by-Design (SSbD) principles which provides methodological guidance to the application of the SSbD principles. The SSbD principles can provide a platform to integrate safety, economic, societal, and environmental design dimensions to design sustainable chemicals, materials, and processes. The incorporation of all these aspects could also be construed as an expansion to life cycle sustainability assessment (LCSA) with an integration of safety considerations. As this framework has just been published, there are still limited case studies, let alone actual approaches in real life to demonstrate the applicability of these SSbD principles. To this end, this study aims to compile and present a list of practical data requirements that would be necessary to perform a life cycle assessment (LCA) and to integrate LCA with the SSbD principles by means of a multi-criteria optimization analysis (MCOA). This study also outlines the process flow approach to envision how the required data can be used to calculate the environmental impacts and combine the end results with the SSbD principles, by using MCOA, with different assessments suggested for the case study involving the mineral carbonation of steel slags as a carbon capture, utilization and storage technology. Therefore, the outcome of this study can be used as a practical approach to generate data and continue with the assessments in order to satisfy all the requirements of the SSbD design principles. Future prospects would include the compilation of the data requirements for the economic and social assessments that can be combined to cover the whole range of the SSbD design principles. In addition to this, the practical approach is also planned to be applied in actual projects where future outcomes could help identify further areas of improvement in order to move a step closer towards a safe and sustainable manufacturing value chain.

5.02.P-Mo420 Monitoring and Evaluating Sustainable Public Procurement: A Multi-Level Methodology Integrating Environmentally Extended Input-Output Analysis and Life Cycle Assessment

***Mila Garcia Valicente**, Lowik Pieters, Anne Hollander, Tinia de Bruycker, Martijn van Bodegraven and Jannie Coenen, RIVM, Netherlands*

Procurement plays a key role in safety and sustainability within organizations. In 2019, the Dutch government spent 85 billion on products and services, accounting for 15% of total procurement in the Netherlands. This spending contributed to 18% of national consumption-based greenhouse gas emissions, 23% of resource use, and 9% of land use. These figures highlight the substantial environmental impact of public procurement, making it a key area for targeted sustainability policies.

Despite its potential, monitoring and evaluating Sustainable Public Procurement (SPP) remains a challenge. Traditional methods for monitoring and evaluation, which rely significantly on the involvement of busy procurement professionals, are often constrained by limited data and require significant time and resources. To address these challenges, we propose a multi-level methodology that combines Environmentally Extended Input-Output Analysis (EEIOA) with Life Cycle Assessment (LCA).

EEIOA provides a high-level analysis of the environmental impact per product group based on monetary flows, enabling the identification of the environmental hotspots. However, it lacks the granularity to guide specific interventions to procurers and suppliers alike. To bridge this gap, LCA is applied to the identified and prioritized hotspots, enabling detailed assessments of individual product groups. This lifecycle-based approach is relevant in the context of the Safe and Sustainable by Design framework, providing actionable insights to support decision-making in public procurement.

Beyond environmental factors, the approach also aims to integrate social dimensions, such as labor conditions and equity in supply chains, providing a holistic approach for evaluating SPP impacts. By combining EEIOA and LCA, this methodology has the potential to improve monitoring and evaluation processes, enabling policymakers to better track progress and refine strategies to achieve sustainability objectives.

While developed for public organizations in the Netherlands, this multi-level methodology could also be adapted to other contexts, offering a useful EEIOA and LCA approach to strengthen the role of procurement in driving sustainability globally.

Disclaimer/Disclosure: This research is funded by the Dutch Ministry of Infrastructure and Water Management.

5.02.P-Mo421 Integrating Agent-Based Modeling and Life Cycle Assessment for Informed Decision-Making in the Energy Transition: A Case Study on Photovoltaics
*Agnese Fuortes[1], Carlos Felipe Blanco Rocha[2], **Joris T.K. Quik**[1] and Willie Peijnenburg[1], (1)RIVM, Netherlands, (2)Leiden University, Netherlands*
The energy transition involves shifting from traditional fossil fuels to renewable energy sources, a process that brings both environmental benefits and societal challenges. A key issue is how to guide this transition effectively, accounting for the complex interactions between energy systems, consumer behavior, and environmental outcomes. Conventional assessment methods often miss these dynamics, leading to incomplete or biased evaluations. To address this gap, we studied integrating Agent-Based Modeling (ABM) with Life Cycle Assessment (LCA) using a metamodel. This combination allows for real-time feedback between consumer decisions and environmental impacts, reducing computational intensity without sacrificing accuracy.
This approach was tested in a case study on photovoltaic (PV) panels, analyzing various scenarios to explore how end-of-life decisions, such as recycling or landfilling, affect environmental outcomes, including resource depletion and climate change. An existing LCA and ABM study on PV panels is adapted for this. The coupling of the two was realized by linking awareness of environmental impacts to consumer behavior towards circular pathways. We utilize concepts like thresholds of concern and thresholds of indifference to adjust consumer attitudes based on the calculated environmental impacts. This analysis revealed that consumer behavior can significantly influence environmental outcomes, particularly through changes in recycling and reuse rates, uncovering unexpected dynamics in sustainability transitions. This study showed that this is a viable approach to coupling an LCA and ABM in order to find potential tipping points in behavior. However, the outcome should be interpreted with care and more robust analysis should be developed to better analyze and understand the factors that are most influential in driving complex dynamics. This is a pioneering study illustrating the benefit and pitfalls of such complex analysis. Future work will expand the application of this integrated framework of LCA and ABM analysis to heat pumps and deepen the interpretation of emergent behaviors to better guide policymakers and stakeholders in the energy transition.

5.02.P-Mo422 Integrating BIM and LCA for Sustainable High-Speed Rail Infrastructure: A Framework for Early Design Stage Environmental Assessment
***Asmaa Benzidane**, ENPC, France*

The building and infrastructure sectors have a substantial impact on the global environment, underscoring the critical necessity for sustainable design practices. This study advocates for the integration of Building Information Modeling (BIM) and Life Cycle Assessment (LCA) to evaluate the environmental impacts of high-speed rail infrastructure projects from the initial design phases, by coupling Building Information Modeling's (BIM) data-filled 3D modeling with Life Cycle Assessment's (LCA) systematic evaluation of environmental impacts.

The objective is to enhance interoperability BIM and LCA tools in order to optimize design and reduce environmental impacts throughout the infrastructure's life cycle. We propose a methodological framework that involves thorough data collection from railway projects, covering design specifics, material specifications, and maintenance needs. An updated BIM-LCA integration framework has been developed using Ecoinvent 3.9.1 for comprehensive and accurate life cycle inventory data. Environmental indicators such as carbon footprint, energy consumption and waste generation are calculated using OpenLCA, allowing real-time feedback on performance. Sensitivity analyses have also been carried out to identify key design and operational factors influencing the environmental results.

Preliminary results from a high-speed rail bridge case study indicate that both the production and maintenance stages alone contribute between 93% and 99% of the impacts: water consumption, land use, freshwater ecotoxicity, human toxicity, marine ecotoxicity and mineral resource scarcity.
A major portion of these impacts was attributed to the production of concrete elements such as piles, beams, and deck slabs. These initial findings highlight the importance of material selection in railway infrastructure projects to reduce their environmental impacts.

This study offers an insight on the potential of integrated BIM-LCA methodologies in promoting sustainable infrastructure design. This approach promotes informed decision-making by allowing for real-time assessment of environmental performance and enhancing data exchange within the BIM and LCA workflow.

5.02.P-Mo423 Decision Support in Safe and Sustainable by Design: A Case Study in the Energy Storage Sector

*Clemens Wolf[1], Julia Wenger[2], Andrea Weiner[3], Anna Spindlegger[4], Aleksander Jandric[4], Matiss Reinfelds[1], Andoni Cruz[3], Florian Part[4], Stefan Spirk[5] and **Claudia Mair-Bauernfeind**[6], (1)BioNanoNet Forschungsgesellschaft mbH, Austria, (2) University of Graz; TU Graz, Austria, (3)Biobide BBD Biophenix SLU, Spain, (4) BOKU University, Austria, (5) Graz University of Technology, Austria, (6) University of Graz, Austria*

Stationary energy storage systems (ESS) are essential for stabilizing grids and ensuring reliable energy supply during the renewable energy transition. Redox flow batteries, as a promising ESS technology, offer scalability and long lifespans, but uncertainties about their safety and sustainability across the value chain necessitate further evaluation to address stakeholder concerns and guide ESS development. In this context, the safe and sustainable by design (SSbD) framework aims to minimize safety and sustainability risks in new materials through a holistic, life-cycle approach. However, uncertainties remain about its practical application to specific products and how to present results clearly to support decision-making at various levels. This study addresses these gaps by exploring the SSbD framework as a decision support tool at two levels: design and technology selection. An organic active element for redox flow batteries was chosen as the focus of the investigation. The assessments conducted (i.e., toxicity, environmental, social, economic, circularity and technical performance assessment) are based on the JRC SSbD framework, extended with use case-specific performance indicators. In each assessment step, several different indicators are evaluated (e.g., 16 impact categories for the life cycle assessment step), resulting in more than 30 indicators overall. Based on these results, a SSbD Matrix will be developed depicting the results in a heat map for the two decision-making levels (design and selection). To refine and validate the SSbD framework, a three-step approach for stakeholder involvement is planned: 1) A workshop with design engineers for the design support tool. 2) A workshop to discuss applicability with the SSbD community. 3) A stakeholder workshop for the selection support framework, with potential consumers (e.g., participants from the energy sector). The SSbD matrix, enabled a comprehensive comparison of electrolytes and batteries by integrating safety, sustainability, and technical performance indicators. It also serves as a stakeholder engagement tool, visualizing trade-offs and performance bottlenecks. By mapping lifecycle hotspots, the matrix provides targeted recommendations for design improvements, material substitution, supply chain management, and recycling strategies. Future research should focus on systematically weighting indicators and refining the matrix to enhance its precision and broader applicability.

Disclaimer/Disclosure: This work is supported by the BMK and the OSALAN through funding of SAF RA Nano EHS Transnational joint call 2022 on safety of advanced materials in energy conversion and storage applications project SuESS through FFG

5.02.P-Mo424 Parametric Life Cycle Assessment of Lithium Production: Prospective Model

***Mehdi Iguider**, Michal Kozderka, Bertrand Rose and Gaetana Quaranta, (1)Universiy of Strasbourg, France*

The European Union has banned the sale of thermal vehicles by 2035, which has increased the demand for electric vehicles. This has resulted in an increased demand for critical battery materials such as lithium. In this context, lithium refining and Lithium-ion battery production in Europe are subjects of global interest and sovereignty concerns. Therefore, there has been a rise of new integrated and non-integrated lithium projects worldwide. Subsequently, several actors are also interested in the environmental impact of battery components. Moreover, the European Union has created several regulations to quantify the environmental impact of battery components, including lithium hydroxide. Chemical (such as lithium) and process-based industries are liable for specific environmental legislation and sustainable practices, especially in the EU. In chemical engineering, the process selected is related to the feedstock impurity profile and the required purity of the final product. Consequently, environmental impacts will be highly variable depending on the feedstock type and processes and to evaluate these environmental impact, Life cycle assessment method (LCA) is used. There is a general lack of studies on the environmental impact of lithium with clear and transparent LCI data. This is the case for Lithium hydroxide production from hard rock and lithium carbonate to lithium hydroxide conversion. Moreover, there is also a lack of prospective modelisation of future lithium extraction and processing projects. This study will evaluate the environmental impact of lithium hydroxide production from spodumene and processed in China. This will be compared with different lithium hydroxide production LCA in the literature, with a focus on European Lithium production. This study will use data from academic and technical documents to collect foreground inventory data. It will use brightway 2 (and activity browser) to evaluate the environmental impact of lithium hydroxide. There will be also a sensitivity analysis by variating different foreground and background data to examine the potential prospective impacts.

Disclaimer/Disclosure: This study was financed as part of ANRT (Association nationale de la recherche et de la technologie) CIFRE PhD thesis by Viridian Lithium S.A.S. (Number 2022/1692)

5.02.P-Mo425 Designing a Sustainable Future: Assessment of a Novel Niobium-Based Anode Material (XNO®) for Lithium-Ion Batteries Using the Safe and Sustainable by Design Framework

***Lígia da Silva Lima**[1], Jianshen Wu[2], Erasmo Cadena[3], Alexander S. Groombridge[2] and Jo Dewulf[3], (1)ARCHE Consulting, Belgium, (2)Echion Technologies LTD, United Kingdom, (3)Ghent University, Belgium*

Rechargeable batteries have become key for several sectors, from electronics to mobility, and play a pivotal role in the energy transition. Batteries not only support the decarbonization of mobility, but they also enable renewable energy storage, which is crucial for minimizing emissions across all industrial sectors. Demand for batteries and raw materials has increased exponentially over the past decades and is expected to continue rising. However, the supply of these materials is often linked to environmental burdens and social rights violations. Thus, responsibly managing the increasing supply of these technologies is critical to achieve a safe and sustainable energy transition. The Safe and Sustainable by Design (SSbD) framework aims to support the design of materials supply processes by implementing sustainable practices in two stages, namely Guiding (re)design principles (stage 1) and Safety and sustainability assessment (stage 2).

This study assesses a novel niobium-based anode material (XNO®) for lithium-ion batteries (LIBs) using the SSbD framework. The XNO® offers superior technical properties and has the potential to replace lithium titanate (LTO) and graphite anodes as it outperforms in several of the SSbD design principles. Some examples are material efficiency (less critical raw materials (CRMs) used), design for energy efficiency (20% less anode material is needed to deliver 1 kWh), use of renewables (renewable electricity in the production phase), design for end-of-life (key raw materials with expected good recovery properties) and consideration of the whole life cycle (from raw material acquisition to end-of-life). Regarding safety and sustainability, the XNO® shows positive results for human health and safety aspects in the production and use (low working conditions and social rights violations risks) and better environmental sustainability assessment, measured using life cycle assessment (e.g. global warming potential 51% lower than LTO and 48% lower than graphite). These results were obtained based on primary data for the XNO®, including battery design and manufacturing models, and literature data for LTO and graphite adapted into the scope of the study using the models.

The findings indicate that XNO® is a promising replacement for widely used anode materials such as graphite and LTO, enabling the substitution of CRMs in a safe and sustainable manner and exemplifying sustainable research and innovation within the SSbD framework.

Disclaimer/Disclosure: Part of the results of this work have been published (https://www.sciencedirect.com/science/article/pii/S2214993723000891) and part has not yet been published.

5.02.P-Mo426 LCA for Biowaste Turned into Value-Added Products

*Rosa Fibla Matamoros[1], Mireia Carrera Vidal[1], **Jorge Senan-Salinas**[1], Cristina Garcia Vera De Lope[2], Regina Pamplona Curiel[2] and Nancy Pena[1], (1)BETA-UVIC, Spain, (2)URBASER, Spain*

As part of the transition towards a post-petroleum society, bio-based industries offer a unique opportunity to establish sustainable, innovative and competitive value chains. The European Commission adopted a new Circular Economy Action Plan in 2020 aimed at finding new ways to valorise high quality waste streams for reuse, remanufacturing and recycling, thus making the circular economy a reality. The CIRCULAR BIOCARBON project presents a first-of-a-kind flagship biorefinery designed to valorize the Organic Fraction of Municipal Solid Waste (OFMSW) and Sewage Sludge (SS) into high-value bio-based products, such as DLC coated products, biodegradable bags, graphene-based devices, compostable films, and biostimulants.
To demonstrate and validate the potential benefits of the project a triple-bottom sustainability impact assessment was conducted. The Environmental Life Cycle Assessment (LCA) was modeled using OpenLCA software based on the EF 3.1 impact assessment method.
Several challenges arose related to methodological decisions taken when modeling multi-output systems. As the biowaste entering the system model transitions from waste to resource, the LCA adopts a production perspective, focusing on the impacts directly associated with the production processes of each building block and bio-based materials. Therefore, several allocation criteria were studied throughout the assessment and a scenario evaluation as carried out.
Despite the promising outcomes, the study underscored the challenges posed by data availability, representativeness, and methodological subjectivity. These challenges complicate comparisons with fossil-based alternatives. This study emphasized the importance of transparent assumptions and the need for further sensitivity analysis, including a waste treatment approach with system expansion to better assess the role of waste treatment in a circular economy.
In conclusion, the variability in data availability, methodological choices, and allocation methods introduces uncertainty into the results, requiring careful interpretation. Hence, methodological choices have significant implications on the outcomes, underscoring the need for standardized approaches when assessing the environmental footprint of bio-based industries.

Disclaimer/Disclosure: Project acronym: CIRCULAR BIOCARBON
GA number: 101023280
This project has received funding from the Bio-based Industries Joint Undertaking (JU) under the European Union s Horizon 2020 research and innovation programme under grant agreement No 101023280. The JU receives support from the European Union s Horizon 2020 research and innovation programme and the Bio-based Industries Consortium.

5.02.P-Mo427 Applying the Safe-and-Sustainable-by-Design Framework: Life Cycle and Risk Assessment of a Microalgae-Based Product

*Marina Isasa, Maria Magdalena Parascanu, Aitana Saez de Guinoa Vilaplana and **Iratxe Fernández**, Tecnalia Research & Innovation, Spain*

Europe is moving towards sustainability to address global environmental challenges such as climate change and environmental degradation. Initiatives such as the European Green Deal and the Chemicals Strategy for Sustainability aim to transform the European economy towards climate neutrality. In this context, the European Commission has developed the Safe-and-Sustainable-by-Design (SSbD) framework, aimed at improving the safety and sustainability of new and existing materials and chemicals throughout their life cycle. This approach integrates methods such as Risk Assessment (RA) and Life Cycle Assessment (LCA) to provide a holistic perspective encompassing health, safety, and environmental sustainability aspects.
This study, developed in the context of SCALE project funded by CBE JU, applies the SSbD framework to evaluate Brainphyt, a microalgae-based ingredient with applications in nutrition, animal feed and food supplements. The combined methodology integrates RA and LCA, focusing on phases 2 and 4 of the

SSbD framework. In phase 2, worker health and safety during production process is addressed through a risk analysis supported by the Social Hotspot Database. This analysis also includes impact categories such as human toxicity, both carcinogenic and non-carcinogenic, and freshwater ecotoxicity, as recommended by PEF methodology. In phase 4, environmental sustainability is assessed using LCA considering 12 environmental impact categories.
The results highlight that, in terms of health and safety, the chemical sector in France and the non-metallic minerals sector in Belgium are the largest contributors to the overall impact. In the categories of human toxicity and ecotoxicity, the use of the photobioreactor and the production of the culture medium account for more than 60% of the total impact, mainly due to the intensive use of chemicals at these stages. In the environmental assessment, the categories with the highest contributions, such as global warming potential, terrestrial ecotoxicity and land use, are also dominated by the culture medium and the photobioreactor. This study highlights the applicability of the SSbD approach to assess emerging products, providing a holistic perspective of their health and sustainability impacts. It underlines the need to optimise critical processes in Brainphyt's production to reduce its environmental impacts and improve safety along the production chain, moving towards a sustainable bioeconomy in the European Union.

Disclaimer/Disclosure: This research is funded by the SCALE European Union s Horizon 2020 research and innovation program and the Bio Based Industries Consortium with the grant reference number 101023593.

5.02.P-Mo428 Applying the Three Dimensions of Sustainability of the Safe and Sustainable by Design framework to Evaluate the Shift From Bisphenol–A-Based to Lignin-Based Epoxy Resins
***Astrid Stalmans**, Lise Asscherickx and Karolien Peeters, (1)VITO, Belgium*
Epoxy resins are synthetic polymers with high-value adhesive and resistance properties used in several industries such as art, automotive, construction and electronics. However, a widely used chemical to produce epoxy resins is Bisphenol A (BPA), a chemical classified as 'Substance of Very High Concern' due to its endocrine disrupting properties. Therefore, lately, concerns regarding the epoxy resins maintenance, end of use and recyclability have been increasing since treating these materials provokes a substantial leak of BPA to the environment.

In this context, the LEGACY project a project funded by NextGenerationEU - aims to produce biobased epoxy resins (using lignin), assuring that the substitution will be superior from both a sustainability and a safety point of view. To substantiate this, the Safe and Sustainable by Design (SSbD) framework will be used, where applications of biobased epoxy coating will be fully assessed through all steps in the extended framework: hazard analysis, human health and safety assessment, environmental assessment and a social and economic assessment. As such, the project will implement all three dimensions of sustainability in the context of the SSbD framework. Combining these results will enable the identification of trade-offs. The newly developed BPA-free product will be tested in two use cases in collaboration with involved companies concerning the application of biobased epoxy resins in coatings. The two demonstrators are situated in the flooring and the sewer piping sectors.

Due to the low Technology Readiness Level (TRL), the environmental impacts will be assessed by means of a prospective Life Cycle Assessment (LCA). The results will be compared to those of the BPA-based resins as a benchmark. Using a scoring system based on the percentage improvements, the impacts will be rated and assigned a level.

The economic impact of the whole value chain of these case studies will also be calculated through a techno-economic analysis (TEA), based on a market study, process flow diagrams and mass and energy balances. Due to the low TRL, the focus will be on identifying the most important parameters that influence the economic feasibility.

Furthermore, the social dimension will be assessed following the UNEP guidelines for social life cycle assessment. The reference scale approach will be followed.

This project plan and approach will be elaborately explained in the poster presentation.

Disclaimer/Disclosure: The presented LEGACY project is funded by the European Union - NexGenerationEU, with the support of the climate, transition and recovery fund.

5.02.P-Mo429 Safe and Sustainable by Design (SSbD) MAX Phases and MXenes: Environmental Impacts Comparison Through Life Cycle Assessment (LCA)

Valeria Acevedo García *and Carlos Bernárdez Casás, AIMEN Research Center, Spain*

MXenes are layered transition metal carbides, carbonitrides, and nitrides produced from layered ternary materials known as MAX phases by selective etching their A-layers. SAFARI project main objective is the SSbD production and utilization of MXenes, covering the whole supply chain, starting from the precursors preparation, MXenes production and functionalization and going to end applications. MAX phases production route based on Spark Plasma Sintering (SPS) and High Energy Ball Milling (HEBM) combination has been adopted to produce 2 MAX phases: Ti3AlC2 and Cr2AlC. Next, Ti3C2 and Cr2C MXenes can be obtained from their corresponding MAX phases via High Frequency Acoustic Emission (HFAE). Chemical digestion (CD) and microwave (MW) as sustainable source of heat were used for the MAX phases etching.

The objective of this study is to determine the environmental impacts of MAX phases and MXenes production via LCA assessment in order to identify hotspots and improvement opportunities, thereby supporting the innovation process. An LCA was carried out following ILCD handbook and ISO14040 methodology. The software SimaPro v9.6 with the database Ecoinvent 3.10 and the ILCD 2011 Midpoint+ method were used. The functional unit was 1 kg of manufactured material (MAX phase or MXene), and the scope was Cradle-to-Gate. Primary data obtained from the production process data (inputs, outputs, wastes and energy requirements) was used.Regarding MAX phases, Cr2AlC has a greater environmental impact than Ti3AlC2 (1.7 times higher). In both MAX Phases, most of the environmental impact is located in the category Human toxicity, cancer effects (1.8 times higher in Cr2AlC), followed by Freshwater ecotoxicity (1.3 times higher in Cr2AlC), Human toxicity, non-cancer effects (1.2 times higher in Ti3AlC2) and Ionizing radiation HH (same for Cr2AlC and Ti3AlC2). Regarding MXenes, the environmental impact of Ti3C2 CD and Ti3C2 MW is very similar. In both cases, the order of the categories with the highest environmental impact remains practically the same as in the case of the MAX Phase, except that Ionizing radiation HH is slightly higher (1 point) than Human toxicity, non-cancer effects. The study highlights the great importance that the choice of the metal to be used in the MAX Phase has in relation to the environmental impacts that the production process of these new materials can cause and also the big impacts that MAX Phases and MXenes production processes have on human health.

Disclaimer/Disclosure: The authors thank SAFARI project. This project has received funding from the European Union´s Horizon 2023 research and innovation programme under grant agreement No. 101135965

5.02.P-Mo430 The Role of SSbD for Pesticides Substitution

***Phatchari Mankong*[1]*, Gunter Brader[2], Stig Olsen[1] and Peter Fantke[3], (1) Technical University of Denmark, Denmark, (2) Austrian Institute of Technology GmbH, Austria, (3)substitute ApS, Denmark; Goethe University, Denmark*

Safe and sustainable-by-design (SSbD) is an emerging concept that can be applied for evaluating different pest control options. However, defining functionally equivalent scenarios for applying SSbD to substitute hazardous pesticides is challenging, especially for contrasting field operations with supply chain impacts in SSbD step 4 on environmental performance. To address this question, we propose a framework to generate functionally equivalent substitution scenarios and test it in a real-world case study. We define conditions for substituting a set of authorized pesticides targeting the same pests. A set of matching tables is integrated into a substitution matrix to compare scenarios. Using this matrix, we compared four pesticide scenarios (Oxathiapiprolin, Laminarin, Folpet + Mandipropamid, and Copper (II) hydroxide) applied in grapes/vine in Europe to prevent Downy mildew, representing chemical, natural, and copper-based fungicides. Life cycle assessment is applied to quantify environmental impacts (SSbD step 4) of all scenarios, and normalization is applied to rank scenarios. Our results show that emissions from field operations of Folpet and Mandipropamid dominate human health impacts. They cause total human toxicity impacts of 0.0014 DALY or 12 hours human life-time lost per 1 hectare application. Pesticide supply chain emissions dominate marine ecotoxicity impacts due to the emissions of 55-62% Aluminium (III), 15-36% Barium (II), and 7-11% Strontium (II). Oxathiapiprolin is identified as overall best-in-class fungicide alternative, followed by Laminarin. Oxathiapiprolin causes 0.2% of overall single-score impact compared with Copper (II) hydroxide. Copper (II) hydroxide shows the highest impacts across alternatives for some supply-chain related impact categories (e.g. human toxicity), while Folpet + Mandipropamid dominate human toxicity and ecotoxicty from field operations. The two latter pesticide scenarios should be considered as candidates for substitution, where environmental conditions, pest resistance and other relevant aspects allow application of proposed low-impact alternatives. The results show that environmental performance at the level of scenario can be improved up to seven orders of magnitude in our case study. Our substitution scenarios will have to consider additional performance criterias (e.g., hazard, worker/bystander health, equivalent efficacy, antagonistic effect, pesticide resistance) to become a viable element in SSbD.

Disclaimer/Disclosure: This work was financially supported by the Sagropia project (grant agreement no. 101136677) funded under the European Union s Horizon Europe Research and Innovation program.

5.02.P-Mo431 Comparative Assessment of Early-Stage Social and Critical Raw Material Assessment in the SSbD Framework: Addressing Current Generic Databases

***Ashrakat Hamed**, Jonas Hoffmann and Andreas Ciroth, GreenDelta GmbH, Germany*

As part of the Safe and Sustainable by Design (SSbD) framework, socio-economic assessments provide a holistic approach by ensuring socio-economic and environmental impacts are considered from the early development stages. However, such assessments, particularly for low Technology Readiness Level (TRL) materials and technologies, remain uncommon and challenging due to limited or unreliable data. Existing social databases, such as PSILCA, are based on current knowledge and can serve as a preliminary tool to identify potential social hotspots. Similarly, tracking data from background databases like ecoinvent, which contain material usage information, offers a useful starting point for assessing critical raw material use in supply chains. In this study, a preliminary comparative assessment was conducted between petroleum-based lubricant and bio-based lubricant (soybean) in terms of social performance and critical raw material consumption. Results reveal that petroleum-based lubricants exhibit higher opportunities for economic development (10% High Opportunity) compared to bio-based lubricants (8% High Opportunity). However, petroleum-based lubricants also present significantly higher social risks, particularly in themes such as "Fair Salary," where up to 52% of the impacts was classified as Very High Risk. Additionally, a comparison of critical raw material consumption shows that soy-based lubricants have a higher environmental impact, with soy-based materials exhibiting substantially higher values in the SH2E Criticality Indicator compared to their petroleum-based counterparts. These findings underscore a key limitation of relying on generic databases for low TRL materials, as the bio-based lubricant was linked to inaccurate supply chain data, which contributed to unreliable impact calculations. This highlights the challenges of using such databases to perform accurate assessments at early stages of technology development, emphasizing the need for more precise and up-to-date data to guide decision-making.

5.02.P-Mo432 Visualization of Nitrogen Flow in Japan Using IDEA Database

***Yuki Ichisugi**, Kenichiro Tsukahara and Kiyotaka Tahara, Nationl Institute of Advanced Industrial Science and Technology (AIST), Japan*

In the concept of Planetary Boundaries, excessive atmospheric nitrogen consumption caused by population increase and economic growth has received widespread attention during recent years. This is due to the use of atmospheric nitrogen, which is released back into the atmosphere and water as reactive nitrogen (ex, NOx, total nitrogen) after it has been used in various processes. Therefore, it is important to analyze the nitrogen flow to reduce the burden on the environment. In previous LCA research, reactive nitrogen has been targeted as elementary flow regarding as environmental burden substance. On the other hand, input data including atmospheric nitrogen, NH? and so on have not been targeted as elementary flow regarding as resource or environmental burden substance.
Additionally, technologies which aim to recycle reactive nitrogen into atmospheric nitrogen for reducing environmental burden have been developed in recent years. In this case, we need to analyze environmental burden in total. Hence, we need not only amount of reactive nitrogen as output data, but also amount of nitrogen as input data. At the same time, we need to confirm the nitrogen balance between input and output to verify the validity of the entire mass balance process because it is significant to reduce the environmental burden in entirety.
In this presentation, we will show the results of nitrogen flow in Japan using IDEA database. We developed the nitrogen input and output amount for each process data in IDEA and analyzed total nitrogen amount of target year, 2015.

5.02.P-Mo433 Integrated Freshwater Risks of Nano-Encapsulated Imidacloprid Versus Its Conventional Counterpart: A Life Cycle Perspective

***Fan Wu** and Jing You, Jinan University, China (Mainland)*

The use of nanopesticides is becoming increasingly widespread; however, current knowledge does not thoroughly address their environmental impacts throughout the life cycle while considering nano-specific properties and environmentally relevant scenarios. To bridge this knowledge gap, we first assessed the cradle-to-gate environmental impacts of imidacloprid (IMI) and nano-encapsulated imidacloprid (nano-

IMI) manufacturing via a life cycle assessment. By coupling the USEtox and SimpleBox/SimpleBox4Nano models, we derived ecotoxicity-characterization factors and impact scores for both IMI and nano-IMI, enabling the quantification of ecological risks associated with their end-of-life emissions. The relative ecological risks of nano-IMI during production (4,631 CTUe) were approximately four times higher than those of IMI (1,177 CTUe). Conversely, the freshwater risks associated with end-of-life nano-IMI release (0.012 6.93×104 CTUe) were at least one order of magnitude lower than those of IMI (1.59×103 6.13×106 CTUe), considering the impacts of rainfall, toxicity data selection, fate, and transport. Under identical rainfall conditions, nano-IMI exhibited substantially reduced integrated freshwater risk compared with IMI, showing potential as an alternative to conventional IMI. This study provides a novel approach for assessing engineered nanomaterial alternatives considering various possible scenarios and offers valuable insights into the risk assessment of nanopesticides throughout their lifecycles for the first time.

5.02.P-Mo434 Life Cycle Assessment of Electronic, Electric and Nonelectric Detonators; A Site-Specific Case for Czech Republic

***Hana Brunhoferova**, Tatiana Trecakova and Vladimir Koci, University of Chemistry and Technology, Prague, Czech Republic*

The widespread use of detonators across industries such as construction and mining introduces significant environmental risks throughout all of their life cycle stages, creating a need to understand and mitigate their generated environmental impacts. Although there have been studies addressing Life Cycle Assessment (LCA) of specific explosives within detonators (e.g. trinitrotoluene, hexogen or octogen), a study about comprehensive environmental evaluation of detonators as whole product is missing. Our study addresses this issue by evaluating the environmental footprints of three most commercially used types of detonators electronic, electric, and non-electric. The electronic detonator is distinguished by e.g. high variability detonation timing and is mostly used for detonations in quarries, metal and nonmetal mines or construction sites. Thanks to its high initiation strength, the electric detonator is suitable for blasting of trenches, shafts or raises. The nonelectric detonator provides excellent water resistance making it suitable for explosions of cap sensitive emulsions. The primary objectives are: 1. to evaluate the environmental impacts of the detonators life cycle phases, 2. to identify which detonator type poses the greatest environmental burden and 3. to propose strategies leading to potential environmental burden mitigation. The LCA includes traditional stages such as comprehensive Life Cycle Inventory (LCI), followed by Life Cycle Impact Assessment (LCIA) according to EN 15804+A2 Environmental Footprint (EF 3.1) with a final interpretation. As functional unit is chosen one piece of detonator with system boundaries set to cradle to grave. Results indicate that the detonators exhibit the highest environmental impacts for categories Freshwater Ecotoxicity, Global Warming Potential and Abiotic Fossil Depletion, with the electronic detonator having the most considerable impact. Based on these findings, we recommend specific measures,

such as adopting metals with recycled content, bio-based and -degradable plastics or alternative fuels, to support more sustainable detonator production and usage. However, the measures need to be adopted after individual proper fit-to-purpose analysis (analysing economic feasibility, technological properties or availability).

5.02.P-Mo435 A Comprehensive Life Cycle Assessment of Carbon Capture Enabled by Metal-Organic-Framework CALF-20

***Ayse Ay**[1], Stefan Marx[1], Susan Dekkers[2], Wouter Fransman[2], Andrea Sudik[3], Pierre Hovington[3] and Wendel Wohlleben[1], (1)BASF SE, Germany, (2)TNO, Netherlands, (3)Svante Inc., British Colombia, Canada*

Metal-Organic Frameworks (MOFs) are crystalline materials made up of metal ions or clusters bonded to rigid organic molecules, forming structures that can be one-, two-, or three-dimensional and often porous. These frameworks are built using coordination bonds between metal ions or clusters and multidentate organic linkers. MOFs are well-known for their large surface areas, adjustable porosity, versatile shapes, high stability, and multifunctional properties, making them suitable for applications such as gas storage and carbon capture. However, there are notable drawbacks, such as concerns about their stability during use and the risk of releasing toxic metal ions or organic components into the environment as they degrade. The environmental impact of MOFs is an important issue, as their long-term behavior and how their components interact with ecosystems are not fully understood. One significant weakness of many MOFs is their stability in water; even small amounts of moisture can affect their structural integrity and porosity. Consequently, the potential for bioaccumulation and toxicity raises serious questions about the safety of using MOFs in practical applications, highlighting the need for further research into their ecological effects.

In this work, by following the Safe and Sustainable by Design principles as implemented in the Triple-S methodology, we employed Life Cycle Assessment (LCA) to focus our comparisons specifically on a Zn-based MOF named Calgary Framework 20 (CALF-20). The objective of this LCA is to evaluate the environmental impact associated with the synthesis of Zinc MOFs, identify hotspots within the life cycle, and optimize the production process while considering both performance and yield. The scope of the LCA encompasses two distinct boundaries: a cradle-to-gate assessment with a functional unit of 1 kg of Zn MOF, and a cradle-to-grave analysis focused on the goal of removing 1 ton of CO2. For comparison within the same design space, we examined five different MOFs such as aluminum fumarate and other CALFs utilized in pulp and paper and cement industry. Additionally, the comparison of different synthesis routes involving solvents is excluded from scope, as the solvents do not align with sustainable practices. By employing LCA methodology, this study aims to provide comprehensive insights into the sustainability and efficiency of Zn MOF production, ultimately contributing to the advancement of environmentally friendly materials.

5.02.P-Mo436 Dual Importance of Method and Data for Robust Sustainability Assessment: Integrating Life Cycle Assessment and Principles of Green Chemistry to Identify More Sustainable Cosmetic Product Ingredients

*Stella Wang, Yuriy Galabura, Candice Novack and **Jennifer K. Saxe**, Kenvue, United States*

Frameworks for guiding sustainable product design draw from various fields, and as a result, use varied data, models and metrics. The Sustainable Innovation Profiler (SIP) is a new software tool that leverages life cycle assessment using the product environmental footprint (PEF) framework and the principles of green chemistry as two alternative lenses through which to evaluate sustainability of chemical substances used as ingredients in cosmetics and personal care product formulas. This tool, described in a separate poster, was created to enable product developers to compare alternative product designs using multiple metrics to avoid blind spots and improve decision making for sustainable innovation.

Robust sustainability assessment relies equally on using scientifically sound methodology and the best available data. To avoid preventable regrettable substitution errors, where more sustainable ingredients are erroneously replaced by less sustainable ones due to outdated or missing data, it is crucial to carefully curate the databases underlying decision tools like the SIP, used to guide product development.

Sustainability assessments generated by the SIP for the formula portion of a cosmetic product require accurate data on the ingredient composition in the formula, environmental sustainability characteristics of ingredients (e.g., environmental degradation rates, carbon emissions, results of aquatic toxicity studies), and the manner of use of the product (i.e., rinsed off after use or not).

This poster shows results of the tool s parallel metrics used to evaluate sustainability for several sets of alternative ingredients (e.g., ultraviolet filter ingredients used in sun protection products). Examples include a demonstration of the higher risk of regrettable substitution errors for ingredients that are under active study by academic researchers, and for which new sustainability data (e.g., from ecotoxicological or environmental fate studies) are being generated and published at a rapid rate. Results also show where trade-offs among the different sustainability metrics for alternative ingredients occur, and for some alternatives, where such trade-offs can be avoided. This work demonstrates the value of using carefully curated data, models, and metrics to evaluate and select among potential alternative ingredients early in the product design process to create cosmetic products with a superior environmental sustainability profile.

5.03 Prospective Life Cycle Assessment for Safe and Sustainable by Design (SSbD) Innovations

5.03.T-01 Prospective Life Cycle Assessment Framework for Continuous Pharmaceutical Production: Upscaling from Lab Scale

***Muhammed Ayaj Ansar**, Ad Ragas, Rosalie van Zelm and Daniel Blanco Ania, (1)Radboud University, Netherlands*

Continuous Flow Production (CFP) has emerged as a sustainable alternative to batch production in the pharmaceutical industry, offering reduced waste, improved heat and mass transfer, and higher yields. However, scaling up lab-scale CFP processes for industrial-level sustainability assessments remains challenging due to data uncertainties and the lack of standardized procedures. This study addresses these challenges by developing a structured framework for scaling up continuous pharmaceutical manufacturing processes for prospective Life Cycle Assessment (LCA). The proposed framework employs a stepwise approach, beginning with a comprehensive literature review to extract relevant lab-scale data, such as synthesis steps, material inputs, and yields. These steps are upscaled using geometric and kinematic similarity, empirical scaling laws, and thermal modelling, supported by collaboration with industrial partners and insights from recent commercial production practices. Logical scenarios were defined to address uncertainties, ensuring flexibility in modelling performance variations in energy use, resource consumption, and emissions. The framework, encompassing nine unit operations and 13 equipment types, enables the estimation of Life Cycle Inventory (LCI) data with minimal resources. This study is the first to develop an estimation method for industrial-scale pharmaceutical production, including product formulation, using optimized commercial equipment designs and performance data. It offers LCA practitioners a practical and efficient tool to evaluate the sustainability of pharmaceutical production processes.

Disclaimer/Disclosure: This work is part of the TransPharm project and was financially supported by the European Union's Horizon Europe research and innovation program under the grant number 101057816.

5.03.T-02 Prospective Life Cycle Assessment of Itaconic Acid Production: Scaling-up and Future-Oriented Scenarios

Dianella Garro-Espinoza[1], *Manja Molgaard Severinsen*[2], *Simone Bachleitner*[2], *Diethard Mattanovich*[2], *Renato Sano Coelho*[3] *and Jorge Senan-Salinas*[1], *(1)BETA Technological Centre, University of Vic - UCC, Spain, (2) Institute of Microbiology and Microbial Biotechnology, BOKU University, Austria, (3)Processium, France*

Carbon capture and utilisation (CCU) technologies can be essential to decarbonise productive sectors and achieve European and global climate goals. Carbon dioxide (CO2) valorisation into chemicals poses several challenges, including the development of innovative, competitive and resource-efficient processes within environmental constraints. Genetically engineered microorganisms have shown the potential for alternative feedstock bioconversion into platform chemicals, including itaconic acid (IA) production from methanol using Komagataella phaffii. However, technological maturity and scaling-up uncertainties are a few of the barriers encountered when assessing the sustainability of such emergent technologies at early development stages. The complexity is further increased when attempting to include future scenarios that depict decarbonised supply chains. To this end, Prospective Life Cycle Assessment (p-LCA) is a tool that addresses scaling-up challenges of low technology readiness level (TRL) technologies whilst considering future scenarios for energy and electricity markets.

This study presents the cradle-to-grave p-LCA for IA production using an engineered K. phaffii strain and two sources of methanol as carbon feedstock: fossil and CO2-based. The latter was modelled from captured CO2 and electrochemically produced hydrogen. The approach for the Life Cycle Inventory followed foreground process modelling from laboratory-scale data using SuperPro designer and an engineering scale-up framework. Prospective modelling followed the SSP2-RCP1.9 pathway for 2020, 2030 and 2050 according to the IMAGE Integrated Assessment Model. The premise tool was used to transform the background database (ecoinvent 3.10 cut-off) within Brightway 2.5. The assessment was conducted according to the EF v3.1 impact method. This assessment included the comparison against a bio-based IA benchmark.

Preliminary p-LCA results showed an improved environmental performance for the CO2-MeOH pathway, underlining the relevance of electricity decarbonisation for CO2 valorisation processes. The comparative against bio-based IA reinforced research efforts to develop strains with improved productivity metrics and low-pH resistance for a competitive CCU technology. Altogether, the study remarked the role of future-oriented scenarios combined with benchmark analysis to support decision making towards the fulfillment of decarbonisation goals within a Safe and Sustainable by Design framework.

Disclaimer/Disclosure: The authors acknowledge the support of the VIVALDI project that has received funding from the European Union s Horizon 2020 research and innovation program under grant agreement 101000441.

5.03.T-03 Designing a Future Plastic Industry Under the Triple Planetary Crisis

Jing Huo[1], *Zhanyun Wang*[2], *Christopher Oberschelp*[1] *and Stefanie Hellweg*[1], *(1)ETH Zurich, Switzerland, (2)EMPA - Swiss Federal Laboratories for Materials Science and Technology, Switzerland*

The global plastic industry, currently fossil-based and linear, contributes to the triple planetary crisis of climate change, biodiversity loss, and pollution. This study presents an integrated optimization model

(PolyLOP) to design and assess future scenarios for the global plastic industry, uniquely addressing all aspects of the triple planetary crisis.
Our findings demonstrate that achieving net-zero greenhouse gas emissions in the plastic industry by 2050 is feasible but requires implementing multiple strategies simultaneously: utilizing alternative feedstocks (lignocellulose residues and captured CO2), maximizing mechanical and chemical recycling, and deploying carbon capture and storage (CCS) for biogenic CO2 emissions. However, this transition creates significant trade-offs. The net-zero scenario results in 20% higher particulate matter-related health impacts compared to a fossil-linear scenario, primarily due to ammonia emissions from biomass cultivation. Additionally, it puts 0.42% of global species at risk of extinction due to increased biomass utilization. The transition faces several critical challenges. Net-zero becomes unfeasible if biomass availability falls below 90% of the projected potential in 2050. The preferred production pathway at low electricity carbon footprint using CO2 feedstock requires substantial hydrogen production, pushing industry electricity consumption to nearly 10 PWh over one-third of current global production. Furthermore, the industry faces a lock-in situation due to existing fossil-based infrastructure, potentially emitting an extra 0.35-0.55 Gt CO2-eq by 2050.
Our analysis reveals that reducing plastic demand is crucial; net-zero emissions become unattainable when production exceeds 1.2 Gt. Regional variations in resource availability and environmental impacts necessitate tailored approaches, with some regions bearing larger biodiversity losses and health burdens while contributing to reduced global emissions. International collaboration through cross-border resource exchange and technology transfer is essential to bridge the gap between regional capacities and global sustainability strategies.
This study illuminates the complex trade-offs between local and global environmental benefits and impacts, enabling informed decision-making and targeted mitigation strategies for the plastic industry's sustainable transition.

5.03.T-04 Material Shortage: A Barrier to Clean Energy and Climate Goals
Fatemeh Rostami[1]*, Richard Cabrera-Jimenez*[2]*, Piera Patrizio*[3]*, Laureano Jimenez*[1]*, Niall Mac Dowell*[3] *and Carlos Pozo*[1]*, (1) Universitat Rovira i Virgili, Spain, (2) ETH Zurich, Switzerland, (3) Imperial College London, United Kingdom*
The importance of clean energy technologies (CETs) in mitigating greenhouse gas (GHG) emissions is well-documented. However, the feasibility of developing CETs timely at the required scales and the consequences of potential shortfalls in their deployment remains underexplored.
This study assesses the achievable capacities of some CETs considering the availability of 36 materials required for their construction. CETs assessed include stationary and electric vehicle batteries, photovoltaic panels, wind turbines, and concentrated solar power (CSP) systems. We depart from 25 CET capacity projections sourced from eight different Integrated Assessment Models (IAMs). These projections, aligned with the Paris Agreement, are translated into material requirements using material intensities for different CETs, and compared with material availabilities obtained from our optimization model. The optimization model aims to minimize the gap between IAM projections and the capacity of CETs that can be realistically built according to estimates on material supply rates.
Shortfalls in CETs will result in additional GHG emissions if unmet capacities are replaced by equivalent business-as-usual services, such as grid electricity or diesel vehicles. Hence, we resort to prospective life cycle assessment (LCA) to calculate GHG emissions that would result from gaps in CET capacities between 2020 and 2050, and ultimately translate these into the equivalent of global warming.
Acknowledging that the impact of these shortfalls in CETs will be dictated by the evolution of the markets, we consider two extreme scenarios. The Current Policy (CP) scenario, reflecting the second Shared Socioeconomic Pathway (SSP2) and Representative Concentration Pathway 3.4 (RCP3.4), projects warming beyond 2 °C, providing an upper bound on the additional GHG emissions. The Net Zero (NZ) scenario, aligned with SSP1 and RCP1.9, limits warming to 1.5 °C and represents a lower bound on the additional GHGs.
We identified significant shortages, with developed capacities falling short by as much as 94% for batteries and PV panels. Depending on the scenario, these shortfalls could contribute to additional warming of 0.06 to 0.95 oC. This underscores the need to incorporate material availability constraints into IAMs to obtain more realistic estimates of CETs and, ultimately, support evidence-based policymaking for a seamless transition to sustainable energy systems in line with the Paris Agreement.

5.03.T-05 How to Decarbonise the Steel Industry? A Prospective Life Cycle Assessment to Compare Different Technological Solutions

Anne Ottenbros[1]*, Mark Huijbregts*[1]*, Nicola Zecca*[2]*, Thomas Hennequin*[3] *and Rosalie van Zelm*[1]*,*
(1)Radboud University, Netherlands, (2) Politecnico di Milano, Italy, (3)TNO, Netherlands

The iron and steel sector ranks first in CO2 emissions and second in energy consumption amongst heavy industries. This study focusses on three decarbonisation technologies for the steel industry, all under development at technological readiness level (TRL) 7: INITIATE, DISPLACE and CASOH. The INITIATE technology uses sorption-enhanced water gas shift (SEWGS) technology to transform blast furnace gas (BFG) and basic oxygen furnace (BOFG) into a suitable feedstock for ammonia and urea production. All CO2 that is left after producing urea can be geologically stored2. DISPLACE, a carbon capture technology using similar hydrotalcite-based adsorbents, uses displacement adsorption to capture CO2 from various flue gasses from the steel production (i.e., sinter plant, hot stoves and reheating ovens)3. Lastly, CASOH, uses calcium-enhanced looping to capture CO2 from BFG, while simultaneously creating an energy rich hydrogen fuel stream3. The captured CO2 in DISPLACE and CASOH is geologically stored.

The goal of the study is to assess the decarbonisation potential of implementing a single or a combination of these technologies in steelmaking on industrial scale. Further, environmental hotspots on human health damage, ecosystem damage, resource scarcity and climate change specifically are identified to provide recommendations towards industrial scale application while minimizing the environmental impact.

We looked at conventional steel production (i.e., base case) and steel production with amine carbon capture technology and storage (i.e., reference case). Life cycle inventory foreground data was modelled in Aspen plus, with background data obtained from a prospective database based on ecoinvent 3.9.1 and IMAGE (SSP2) future scenarios made using premise.

It was found that CASOH in combination with DISPLACE and the INITIATE technology can achieve large reductions in climate change impacts compared to conventional steel production and steel production with amine carbon capture. Specifically, reductions of 1116 kg CO2-eq/ton HRC steel to 1283 kg CO2-eq/ton HRC steel compared to the base case are found, respectively. These technologies can aid in the decarbonisation of the steel industry and fertilizer industry.

Disclaimer/Disclosure: The authors acknowledge the financial support from C4U Project funded by the European H2020 research and innovation programme under grant agreement no 884418 and from the INITIATE project funded by the European Union s Horizon 2020 research and innovation programme under grant agreement No 958318.

5.03.P Prospective Life Cycle Assessment for Safe and Sustainable by Design (SSbD) Innovations

5.03.P-Mo437 SSbD Approach to Enhance the Environmental Sustainability of Industrial Washing Processes through Usage Biodegradable Detergent Based on Life Cycle Assessment

Anastasiia Timofeeva *and Giampaolo Campana, University of Bologna, Italy*

Industrial washing processes in automated production face a number of environmental challenges including significant wastewater pollution and consumption of non-renewable resources. There is a need for safe and sustainable alternatives to conventional detergents that maintain cleaning efficiency but minimise negative environmental impacts. The study focused on applying the Safe and Sustainable-by-Design (SSbD) approach to optimise washing processes traditionally characterised by high energy, water consumption and the use of chemically aggressive detergents. The main objective of the study is to reduce the environmental footprint of washing processes in automated manufacturing by introducing a biodegradable detergent and assessing its impact through Life Cycle Assessment (LCA) methodology in Step 4 of SSbD approach.

In this study, the washing process using a new generation biodegradable detergent was modelled and compared with conventional detergents using the LCA method (ISO 14040/44). Step 4 of the SSbD approach was applied to assess the environmental sustainability and safety of the selected solution. The analysis included an examination of the environmental impact of washing processes with different detergent use, mainly during the use phase of the compared products. The study assessed key indicators such as carbon footprint, water footprint, ecotoxicity and energy consumption.

Preliminary data showed that transition to a biodegradable detergent resulted in a reduced carbon footprint compared to conventional counterparts. Ecotoxicity was reduced due to the improved formulation of the detergent and its biodegradability reduced the load on wastewater treatment systems. Additionally, there was a reduction in energy consumption while maintaining equipment cleaning standards.

The study demonstrates that the use of biodegradable detergents based on the SSbD framework significantly reduces the environmental footprint of the washing processes while maintainin g high cleaning efficiency. The results highlight the potential of integrating SSbD into different operational processes as a key strategy to achieve environmental sustainability. These findings are applicable for scaling to other industries with high environmental burdens, promoting the principles of circular economy and sustainable development.

5.03.P-Mo438 Prospective Life Cycle Assessment of Advanced Materials – The Case Study of Graphene Oxide in Drinking Water Filters

*Veronique Adam[1], **Rayén Chantal Mentler**[1], Matteo Vezzali[2], Letizia Bocchi[2] and Blanca Suarez-Merino[1], (1)TEMAS Solutions GmbH, Switzerland, (2)Medica SPA, Italy*

The European Commission, in its Recommendation for the implementation of a framework for safe and sustainable by design (European Commission 2022), advises to use Life Cycle Assessment (LCA) to evaluate the environmental sustainability of chemicals and materials. However, its applicability to Advanced Materials (AdMa) can be challenging due to lack of data, pertaining to the novelty of these materials and their production processes. In this practical case study, we are exp loring how prospective LCA can be implemented to assess the environmental impacts of producing a polysulfone graphene oxide (PSU-GO) membrane used in drinking water filters.

The lifecycle inventory was built on exchanges of information with the filters pro ducer, enabling the use of first-hand foreground data for a contribution. Using Environmental Footprint v3.1 and Impact World+ Midpoint v2.0.1, and as expected for inventories created for early stages of product development, results showed that equipment contributed to more than 95% of the process impacts for all impact categories. When excluding the contribution of equipment to the impact assessment, electricity and the raw material N-methyl-2-pyrrolidone (NMP) were the main contributors (e.g. 45% each of impacts on freshwater ecotoxicity using EF v3.1).

In a next step, to better approximate material and energy uses and evaluate the contribution of equipment to the impacts, a methodology is being developed to upscale this pilot process to an industrial sca le. Based on manual calculations and use of proxies, the impacts of the foreseen industrial production process are compared to those of the same filtration membrane without GO. To ensure the functionality is consistent in both systems compared, activated carbon will be fictively added to the filtration membrane not containing GO.

The potential implications of these results on the design and development of the industrial process are discussed, as well as learnings on the applicability of prospective LCA for SSbD.

5.03.P-Mo439 Prospective Life Cycle Assessment of a Modular Shared Autonomous Vehicle Production Phase

***Albert Jan van Zuilichem**, Technical University Darmstadt, Germany*

The transportation sector s greenhouse gas emissions have driven research into sustainable vehicle production. This study presents a Life Cycle Assessment (LCA) of a prototype Modular Shared Autonomous Vehicle (MSAV), focusing specifically on its production phase to explore environmental impacts relative to conventional electric vehicles (EVs). By concentrating on production impacts in the early stages of MSAV development, we aim to inform strategies incorporating Safe and Sustainable by Design principles into emerging vehicle technologies.

This case study utilizes primary data on materials and manufacturing methods unique to the MSAV, which is rarely available in vehicle LCA studies. We apply prospective LCA methods to develop future production scenarios that include renewable energy adoption, advances in material efficiency, and emerging manufacturing techniques like additive manufacturing. In particular, we model improvements in high-impact materials such as carbon fiber and additional electronics used in the autonomous driving system, both of which significantly influence the environmental footprint of the MSAV s production phase. As recycling options, manufacturing efficiencies, and production technologies evolve to higher Technology Readiness Levels (TRL), these materials and components are expected to become more sustainable.

Preliminary results indicate that, due to added electronics and specialized materials, the MSAV s production phase currently has a higher environmental impact than conventional EVs. However, scenario modeling suggests that future advancements in manufacturing methods, including additive manufacturing, as well as improved energy sourcing and material innovation, could significantly reduce the environmental impacts associated with MSAV production.

Our findings highlight the potential of forward-looking production strategies to align MSAV design with Safe and Sustainable by Design principles. By providing insights into future production scenarios and design improvements to reduce environmental impacts, this study acts as a foundation for policymakers, manufacturers, and researchers dedicated to advancing sustainable urban mobility. This work emphasizes the critical role of early design and production choices in shaping a cleaner, more resilient future in transportation.

5.03.P-Mo440 Ex-ante Life Cycle Assessment of Lipids Extraction from Insect Biomass

***Francesco Celauro**, University of Bologna, Italy*

Research on insects as an alternative food source has been developing in the last decade. They offer advantages such as a high nutritional value and protein content, with a lower environmental impact compared to traditional livestock.

The use of insect biomass, however, is not relegated to food applications as it can be a viable substitute as an oil source for cosmetic applications, having a similar chemical composition to currently used vegetable oils. In this context, the PINSO project is a research endeavor from Thomas More and KU Leuven that aims to demonstrate the feasibility of insect lipid production on a pilot scale and the technological and economic viability of further scaling.

Environmental sustainability assessment is an integral part of the process, conducted through the Life Cycle Assessment methodology according to ISO 14040 standards.

The research project comprises two phases: the LCA of the pilot plant in Geel (BE), with lab-scale oil extraction from Tenebrio molitor larvae, and a conceptual scale-up of the process and estimate of the associated energy and mass balances, to then perform an ex-ante sustainability assessment, using a hybrid scale-up framework from existing literature.

Results may be relevant in offering insight on environmental hotspots of the process, to suggest further research on the optimization and industrial applicability of the process.
Furthermore, uncertainty of results is discussed and suggestions for further research are presented.

5.03.P-Mo441 Revealing Biodiversity Impacts of Land Use Intensification: A Spatio-temporally resolved Global Assessment (2005–2019)

***Veronika Schlosser**[1], Livia Cabernard[1] and Laura Scherer[2], (1)Technical University Munich, Germany, (2)Leiden University, Netherlands*

Land use is the key driver of biodiversity loss, yet its full impacts remain underestimated due to the lack of consideration for land use intensity and the absence of spatio-temporally resolved inventory data [. This study assesses spatially-resolved biodiversity loss from land use intensification from 2005 to 2019. We identify critical biodiversity hotspots and quantify the effect of land use intensity on global extinction rate. A global dataset of land use was compiled from satellite-based sources, classifying land use into three levels of intensification (minimal, light, and intense) across various land types, including crops, pasture, plantations, managed forests, and urban areas. Using characterization factors (CFs) accounting for land-use intensities and five species groups, we estimated extinction rates on ecoregion-level and compared our results with UNEP-SETAC methods. Preliminary results show that land-related biodiversity loss has accelerated over the 2005-2019 period, with a global extinction rate reaching 17 % in 2015. This is almost two times higher compared to previous studies that did not account for spatially-resolved land use intensification. Hotspots of biodiversity loss include Brazil, Mexico, Southeast Asia, and East Africa, with significant increased extinction rates due to intensified use of pastures, plantations, and managed forests. These findings underscore the importance of incorporating land use intensities into biodiversity impact assessments, revealing the urgency of adopting more sustainable land management practices. By integrating spatio-temporally resolved remote sensing data and applying refined characterization factors, this study offers valuable insights for improving conservation strategies and informing policies to mitigate biodiversity loss in the face of global food demand and environmental pressures.

5.03.P-Mo442 Influence of Different Uncertainties Types in Prospective LCA: A Case Study on Organic Active Materials for Flow Batteries

***Julia Wenger**[1], Anna Spindlegger[2], Georg Rudelstorfer[3], Dominik Wickenhauser[4], Michael Mayr[5], Aleksander Jandric[2], Florian Part[2], Ulrich Hirn[4], Stefan Spirk[4] and Claudia Mair-Bauernfeind[5], (1) Graz University of Technology; University of Graz, Austria, (2) BOKU University, Austria, (3) Graz University of Technology; ECOLYTE GmbH, Austria, (4) Graz University of Technology, Austria, (5) University of Graz, Austria*

The sustainability and safety of stationary energy storage systems (ESS) such as redox flow batteries (RFB) have recently become an issue, particularly since ESS are considered to play an essential role in renewable energy transitions. Organic active materials (for redox-flow batteries, ORFB) produced from industrial by-products, e.g. lignin, may be advantageous regarding sustainability considerations. However, this cannot be taken for granted and given the currently low technology readiness level (TRL) and, consequently, high uncertainties prevailing, continuous evaluation of ESS options seems highly relevant. Since the provision of point estimates for environmental impact (EI) comparisons of battery alternatives may lead to poor decision-making towards Safe and Sustainability-by-Design (SSbD) innovations, different types of uncertainties need to be identified, systematically addressed, and communicated. Therefore, the aim of this work is to identify and characterize uncertainties present in ESS (and particularly ORFB) development and to take these into account with a prospective analysis approach. In setting up the production-phase inventories, related uncertainties are considered in several ways which are addressed and discussed in this work. In addition, since the operation and EoL of batteries are the phases associated with the most uncertainties, an equation-based model is proposed for the calculation of EIs under consideration of specific use-phase-related technical performance parameter settings for respective ESS systems and application scenarios. Preliminary cradle-to-use Monte-Carlo results depicting potential use-phase-induced ranges of EIs (Global Warming Potential, GWP) indicated that (uncertainties regarding) battery cycle-life and (future) energy sources used for charging/discharging showed to be substantial for the potential extent (ranges) of use-phase induced GWP impacts. This way forward should enable more substantiated comparisons between ESS options and support decision-making on related SSbD innovations. A better and more systemic understanding of potential EIs of ESS technologies that are currently (partly) at lower TRLs, identification of hotspots, key levers, and trade-offs, as well as grasping how prevailing uncertainties change in the course of the technology development process are further aims followed. As a starting point, this study provides suggestions on how these issues could be tackled and presents first results.

Disclaimer/Disclosure: This research is supported by the BMK and the OSALAN through funding of SAF RA Nano EHS Transnational joint call 2022 on safety of advanced materials in energy conversion and storage applications project SuESS through FFG. This research has received funding from the European Innovation Council (EIC) under grant agreement No 101115293 (VanillaFlow).

5.03.P-Mo443 Implementing Prospective Life Cycle Assessment in Process Systems Engineering: A Case Study of Bio-Based Acrylic Acid Production from Wheat Straw Through Thermo-Mechanical Pulp Mill Side Stream

***Safdar Abbas**[1], Stavroula Zervopoulou[1], Sebastian Serna-Loaiza[2] and Stavros Papadokonstantakis[1], (1)TU Wien, Austria, (2)Sphera Solutions GmbH, Germany; TU Wien, Austria*

Acrylic acid is a valuable platform chemical with significant potential for conversion into commercially essential products, including acrylates, sodium polyacrylate, polyacrylic acid, acrylamide, and polyacrylamide. Currently, the primary method for industrial acrylic acid production involves catalytic oxidation of fossil-based propylene, a process associated with stringent safety requirements and substantial environmental impact. Alternatively, bio-based acrylic acid production from wheat straw through thermo-mechanical pulp mill side streams offers a more sustainable pathway. A prospective life cycle assessment (pLCA) is an essential approach for early-stage evaluation of this innovative biochemical pathway, allowing for a comparative analysis between bio-based and fossil-based acrylic acid production. This assessment provides valuable insights to guide and support stakeholders and decision-makers in advancing sustainable production methods. The study aims to identify environmental hotspots during the initial development phase, using a cradle-to-gate system boundary and a functional unit of 1 kg of acrylic acid. Two-time horizons are considered: the present year, 2024, and future years up to 2050, when industrial-scale implementation of this biochemical pathway is anticipated.
The assessment incorporates three prospective scenarios, aligned with the Paris Agreement s climate

targets for energy system development, based on scenarios of an integrated assessment model (IAM), the REMIND model, which are the i.e., REMIND-SSP2-Base (projecting a 3.5°C temperature rise by century s end), PKBudg1150 (targeting below 2°C by 2100), and PKBudg500 (aiming for a cap below 1.5°C by 2100), corresponding to milestones in 2030, 2040, and 2050. Using the ReCiPe 2016 v.1.03 life cycle impact assessment (LCIA) method, this study performs a hierarchical midpoint assessment to quantify environmental impacts, focusing on global warming potential (GWP) measured in CO? equivalents. Results reveal that the primary contributor to GWP is the energy-intensive evaporation process required to concentrate the diluted side stream, marking it as an environmental hotspot. Findings also indicate that as future energy production becomes more sustainable, the viability of bio-based acrylic acid production improves. Overall, bio-based acrylic acid demonstrates a lower GWP than fossil-based acrylic acid for both current and future scenarios.

Disclaimer/Disclosure: Acknowledgment - The authors gratefully acknowledge financial support by TU Wien's global budget for PhD research.

5.03.P-Mo444 Generative Multi-Agent Framework for Prospective Life Cycle Assessment Aligned with Safe and Sustainable by Design Principles

Jinliang Xie[1]*, Yuzhen Feng*[1]*, Si Zhang*[1]*, Ziqi Wang*[1]*, Yunduo Lu*[1]*, Jiayi Yuan*[1]*, Wenjie Shi*[1]*, Ziqian Xia*[2]*, Chuke Chen*[1]*, Hang Yang*[1]*, Changqing Xu*[3]*, Jing Guo*[1]*, Nan Li*[1] *and Ming XU*[1]*, (1)Tsinghua University, China (Mainland), (2)Tongji University, China (Mainland), (3)Beijing Institute of Technology, China (Mainland)*

This research presents the "CarbonQi" framework, a generative AI-driven approach for prospective life cycle assessment (LCA) of emerging technologies, with a focus on battery technologies. By leveraging generative AI's high-level reasoning and dynamic modeling capabilities, the framework addresses the challenges of incomplete data and rapid technological changes in early-stage development. The modular design enables flexible updates, providing real-time carbon footprint predictions, and enhancing decision-making for low-carbon strategies. This innovative method supports Safe and Sustainable by Design (SSbD) principles by enabling early environmental impact assessments, ultimately guiding the design of more sustainable technologies.

5.03.P-Mo445 ProScale-E: Ecotoxicity Potential Assessment, from Method Development to Application

Rosella Telaretti Leggieri*, Swedish Environmental Research Institute (IVL), Sweden*

This abstract presents the application of the recently developed ProScale-E method for ecotoxicity potential assessment within a case study. Previously, the ProScale method covering direct exposure related human toxicity potential, here referred to as ProScale-H, was established as a method based on a straightforward mathematical formula, aligned with REACH as much as possible, and requiring little to moderate substance data while still providing meaningful results. From collaborative work among participating consortium members, the ProScale-E method was recently developed according to similar principles and presented to the whole ProScale-E consortium in May 2024. ProScale-E is proposed as a promising method for safe and sustainable by design (SSbD) chemicals assessment in early innovation stages. In the current work, the ProScale-E method was applied within a case study simulating impact assessments at early innovation stages, i.e. with limited information available, for instance on hazard data and chemical emissions. Here, the authors focused on assessing the ecotoxicity potential of bisphenol A (BPA) based polycarbonate within a cradle-to-gate system (which may be extended to cradle-to-grave).

Within this case study work, the product system of BPA-based polycarbonate was modelled with ProScale-E. The results of a ProScale-E assessment correspond to a hazard- and degradation-based score giving quantitative information on direct chemical risks for the environment. According to default worst case release factors based on Environmental Release Categories (ERCs) and Specific ERCs (SpERCs) (as proposed by ECHA for environmental exposure assessment within REACH), the authors modelled emissions to air, water and soil. The preliminary results allow to identify the hotspots: chemical emissions with highest ProScale-E score, resulting in a large contribution to the overall impacts.

The ProScale-E method for ecotoxicity potential assessment was applied to BPA-based polycarbonate. The model could successfully translate REACH data into ecotoxicity potential of modelled emissions throughout the life cycle of the studied product. Worst case release factors derived from ERCs and SpERCs allowed for a rough modelling of substances release to air, water and soil. It is here suggested that by applying this method the ProScaleE practitioner can easily identify ecotoxicity hotspots.

5.03.P-Mo446 Advancing Maritime and Aviation Fuels Through Prospective LCA: A Safe and Sustainable by Design Approach

*Morten Birkved, **Samaneh Fayyaz**, Hadis Marami and Benyamin Khoshnevisan, SDU-IGT, Denmark*

The maritime and aviation sectors significantly contribute to global greenhouse gas (GHG) emissions, accounting for approximately 3% and 2%, respectively. In response, both industries are pursuing ambitious decarbonization strategies. The International Maritime Organization (IMO) aims to achieve net-zero GHG emissions from international shipping by 2050. Similarly, the aviation sector has proposed halving GHG emissions compared to 2005 levels by 2050. Both sectors prioritize sustainable fuels with maritime investments in alternative fuels like ammonia, methanol, and lignin-alcohol (Li-OH) fuels, and aviation focusing on sustainable aviation fuels (SAFs).
Studies have rarely assessed the environmental impacts of low TRL technologies based on the time required to establish them at full scale. To bridge this gap, we propose a prospective environmental assessment framework integrated shared socioeconomic pathways (SSPs) within a consequential context, providing a realistic picture of the environmental impacts of alternative fuels under varying future scenarios.
Our framework assesses uncertainties in scaling technologies and future scenarios, helping researchers evaluate how alternative fuels align with sustainability goals and guiding decision-makers in selecting technologies that minimize trade-offs while maximizing benefits. A Python-based tool was developed to integrate OpenLCA with an integrated assessment model (IAM)-based consequential prospective database. This tool enables value chain assessments of alternative fuels across SSPs, RCPs, and their TRL-related timeframes until 2050. The analysis includes midpoint and endpoint results from prospective consequential LCAs, offering a robust system-wide perspective for Safe and Sustainable by Design (SSbD) innovations.
An interactive dashboard allows users to explore impacts and damage categories across value chains, SSPs, RCPs, timeframes, and technical options. To demonstrate its applicability, the framework was used to assess the production of SAF via the Fischer Tropsch (FT) process, alongside e-gasoline as a by-product and Li-OH via solvolysis process. These findings illustrate the framework s potential to guide sustainable design and development aligned with SSbD principles, enabling a forward-looking approach to decarbonization in maritime and aviation sectors. This versatile tool fosters safer, more sustainable innovations for a carbon-neutral future.

Disclaimer/Disclosure: This research is supported by two key projects. The MAT-Fuel project (https://projekter.au.dk/mat-fuels) is funded by Aktieselskabet D/S Orient's Fond, providing resources to advance the study of sustainable marine fuels. The views and opinions expressed in this abstract are solely those of the authors and do not necessarily reflect the official policies or positions of the funding bodies.

5.03.P-Mo447 Toward Circular Shifting of Phosphate Mining Industry in Morocco: Scenarios and Prospective LCA

***Safa Rachid**[1], Titouan Greffe[2], Cecile Sophie Marie Bulle[2], Mostafa Benzaazoua[1] and Yassine Taha[1], (1)Mohemmed VI polytechnic university, Morocco, (2) UQAM, Canada*

With the global population continuing to grow, the demand for food, particularly processed foods and animal products, has surged, making food security an increasingly pressing issue. Phosphorus (P) plays a critical role in ensuring a stable food supply for the future. However, recent studies reveal that nearly 50% of phosphorus is lost during the mining stage, significantly more than in other life cycle stages.

This work addresses the question: What is the impact of closing the loop on phosphate mining in Morocco? As the world's second-largest producer of phosphate rock, Morocco represents a pivotal case study. A previous assessment of the business-as-usual scenario identified key hotspots, forming the basis for this study s exploration of new mitigation strategies grounded in circularity principles.

Preliminary results offer insights into the projected impacts by 2050 for both SSP1 and SSP2, laying the groundwork for a comparative assessment of the developed scenario's long-term effects. This analysis aims to provide the scientific community and policymakers with actionable knowledge to advance sustainability in phosphate resource management

Disclaimer/Disclosure: This project was financially supported through the research program between OCP Group and UM6P under the specific agreement AS34.

5.03.P-Mo448 Evaluating Sustainability: Life Cycle Assessment of Hybrid Biological-Inorganic Systems for Safe Nitrogen Recovery from Wastewater

*Benyamin Khoshnevisan[1], Nahid Taherzadeh-Shalmaei[2], Mohammad Sharifi[2], **Hadis Marami**[3] and Morten Birkved[1], (1) University of Southern Denmark, Denmark, (2) University of Tehran, Iran, Islamic Republic of, (3)SDU-IGT, Denmark*

Wastewater treatment plants (WWTPs) are essential for safeguarding public health and producing environmentally friendly, reusable water. However, they face challenges related to high energy consumption and greenhouse gas emissions during treatment processes, particularly in the nitrification-denitrification phase, which is critical for nitrogen removal. The primary challenge is the inefficient recovery of valuable resources, such as nitrogen, in current wastewater management practices. This study aims to explore the integration of hybrid biological-inorganic (HBI) systems within WWTPs as a solution for nitrogen recovery and microbial protein (MP) production, thus enhancing sustainability. To address this challenge, the study incorporates HBI systems that utilize hydrogen-oxidizing bacteria (HOB) and external carbon dioxide (CO?) to recover nitrogen from wastewater. A dynamic life cycle assessment (LCA) aligned with the shared socioeconomic pathways (SSPs) will be conducted to evaluate the environmental sustainability of this integration. The assessment examined two modes of CO? supply amine-based carbon capture (CC) using monoethanolamine (MEA) and direct air capture (DAC) considering both biogenic/atmospheric and fossil sources. The research employs a prospective assessment of background and foreground changes using principles of consequential life cycle assessment (pCLCA), focusing on scenarios up to 2050. This framework helps ensure that sustainability is considered in the early design stages of innovative projects. Results indicate that HBI systems have the potential to advance wastewater treatment by enhancing sustainability through improved global warming potential (GWP) and effective resource scarsity, thus promoting the development of more environmentally friendly wastewater management practices under SSP2. Additionally, the use of the monoethanol amine (MEA) method for carbon supply yielded better outcomes than direct air capture (DAC) due to effective heat recovery. The instability of HBI system integrated with WWTPs can be attributed to the significant environmental emissions associated with the electrolyzer used for hydrogen production. These findings underscore the need for further optimization of the HBI system to enhance its applicability in various scenarios.

5.04 Advancements in Life-Cycle Inventory (LCI): Enhancing Data Collection and Management, and Addressing Temporal Aspects

5.04.T-01 Supporting the Desing of Renewable Energy Scenarios: EnergyPLAN-LCA Framework

***Lasse Krogh Poulsen**, Iva Ridjan Skov, Henrik Lund, Lotte Ansgaard Thomsen and Soren Lokke, Aalborg University, Denmark*

As energy systems are transitioning towards renewable energy in place of fuel combustion, the main environmental impacts are also shifting from direct combustion impacts to indirect construction and maintenance impacts. These types of impacts are rarely accounted for in energy systems modelling (ESM), and therefore, LCA integration in ESM is vital to assess these indirect impacts and potential trade-offs with other environmental impact categories e.g., land use. By integrating prospective LCA and the EnergyPLAN modelling tool, we can simulate different energy transition scenarios which can be assessed at temporal resolutions ranging from a whole year down to a specific hour, including seasonal weather patterns and energy demand fluctuations. These different scenarios can then be compared to account for potential trade-offs and the temporal differences in energy capacity construction versus avoided impacts from electricity production in the longer term. To this end, we use Premise to create prospective background databases, and national energy scenarios to provide foreground systems with relevance for national decision-making.

We have demonstrated the tool on the IDA Climate Response scenarios for a climate-neutral Danish energy system in 2045. It has been found that even though the scenario is climate-neutral when only accounting for combustion emissions, it is not so when accounting for the whole life cycle. However, compared to the reference scenario, it still performs better in the long-term, and the massive renewable energy capacity construction required to realize the IDA scenario pays itself back within 11 years in terms of GHG emissions saved compared to the reference scenario, even when applying GWP100 discounting to future (avoided) emissions. This return on investment can be analyzed across various impact categories.

The relevance of the tool was demonstrated on the IDA scenarios ex-post but can and should ideally be applied in an iterative modelling process between ESM and LCA to ensure modelling of scenarios with minimal environmental impacts on as many impact categories as possible.

5.04.T-02 SHRECC: Simple Hourly-Resolution Electricity Consumption Calculation
*Thomas Gibon, Enrico Benetto and **Sabina Bednářová**, Luxembourg Institute of Science and Technology (LIST), Luxembourg*
Rapid changes in electricity supply patterns caused by a growing share of renewable sources and increased international exchanges - can lead to misrepresentations in life cycle inventories (LCI) of electricity mixes over time, resulting in flawed life cycle impact assessment (LCIA) results, particularly for electricity-intensive systems, and incompatibility with new directives.

Databases like ecoinvent, widely used by LCA practitioners, often rely on annual averages from [year n-3] and fail to account for differences in electricity production mix throughout the year. With the rise of intermittent electricity production, production mixes can vary significantly by hour, month, or season. Coupled with fluctuating consumption, relying on average mixes can distort life cycle impact estimates. This challenges the notion that electricity mixes variability reflects ontic uncertainty, as we argue it can be systematically captured to enhance result reliability, reduce uncertainty, and potentially optimize studied systems.

This study addresses this research gap by developing a tool (a python package shrecc) that collects high-resolution hourly electricity high voltage production and consumption data via the Energy Charts API. The data is parsed, matched with ecoinvent classifications using ENTSO-E datasets, converted to low-voltage mixes, and made available as a ready-to-use brightway-compatible database. Practitioners can select countries and time intervals (one-off or reoccurring), enabling more precise and user-friendly integration into LCA models.

We show the impact of our tool on an LCA study of an electric agricultural robot. The functional unit is manufacture and operation of one electric robot for its lifespan of 15 years in France and Greece. The robot must be charged before its operation for 1h/day, and such charging can take place at different times of the day. We used brightway for the LCA and the shrecc package to produce low-voltage electricity mix LCIs used in the operation phase. We showcase the importance of selecting the charging hour versus using the average electricity mix, on two different electricity mixes: carbon intensive and low carbon mix. Selecting a specific hour (8am and 10pm) compared to using the annual mix shows systematically lower LCIA scores, in both countries and all 6 selected impact categories. This highlights the importance of using time-specific electricity LCIs in LCA studies.

5.04.T-03 Toxicity Assessment of Agricultural Raw Materials: Addressing the Major Shortcoming of Substances' Inventory Data in a Changing (Regulatory, Technological and Climatic) Landscape
*Joséphine Gatin and **Anne Asselin**, SAYARI, France*
The assessment of toxicity impacts from chemical substances in Life Cycle Assessment (LCA) faces challenges due to data gaps in Life Cycle Impact Assessment (LCIA) and Life Cycle Inventory (LCI). Notably, there is a lack of consistent, specific and up-to-date inventories regarding types and quantities of plant protection products (PPPs) used for various agricultural productions. Our research addresses this data gap. We developed a model and tool to identify the PPP active substances names and quantities used for major French crops productions. It relies on 3 complementary national public databases:

- The Farm Accountancy Data Network (FADN), providing annual regional agricultural productions and economic PPP purchase data
- The National Phytopharmaceutical Sales Database (BNV-d), detailing annual French PPP purchase volumes by region
- The Ephy regulatory database, specifying active substances contained in PPP and their authorized uses on French agricultural productions.

Combination of those 3 databases enabled us to generate active substances inventories for 51 French productions, with granularity at active substance level. The inventories were generated for each year between 2015 and 2022 at both regional and national scales. The results were compared to the PPP inventories of Agribalyse 3.0. showing consistency with our results. We then assessed the representation of these active substances in commonly used impact assessment methods. A substantial proportion of the substances in our inventories were not characterized in USEtox2.13 (ecotoxicity). In contrast, the Environmental Footprint (EF3.1) method demonstrated significantly better coverage of active substances; however, it still did not account for all substances identified in our inventories. Our method allowed for the automated generation of detailed substances' inventories for major French agricultural productions, using yearly updated databases to reflect changes in regulations and usage. This approach enhances the granularity of PPP inventories, facilitating their integration with increasingly precise toxicity assessment methods. However, further validation of the model is necessary (and on-going), particularly through comparisons with additional data sources, to ensure its robustness and reliability.

5.04.T-04 Inventory Data Curing for Circular Clothing Business Models and Uncertainty

Sarah Gray[1]*, Jhuma Sadhukhan*[2]*, Angela Druckman*[2] *and Keith James*[1]*, (1)The Waste and Resources Action Programme (WRAP), United Kingdom, (2)University of Surrey, United Kingdom*

This presentation will outline steps taken to improve the quality of data available for decision-making about circular clothing business models (CCBMs), such as sale or rental of secondhand clothing. Including product use in life cycle assessment (LCA) is valuable where the use phase is important to the results. For CCBMs, including use is essential to reflect the difference that a change in business model makes to the liespan of the garment.

A review of existing life cycle inventory (LCI) data was conducted for clothing use and CCBMs and data compiled to represent both conventional clothing acquisition and use and that using a range of different business models. Data in the LCI were quality assessed and each input scored using a Pedigree Matrix approach. Consumer survey data for the use phase of clothing was accessed to improve on the LCI data for critical aspects including the number of garments in the wardrobe and duration of use. An LCA was carried out, including analysis of a variety of scenarios followed by uncertainty analysis using Monte Carlo simulation.

The results of the review of LCI data showed scope to improve available data concerning garment use, especially concerning garments acquired using CCBMs. The results of the LCA showed significant reduction in environmental impacts could be achieved by acquiring half of garments in the average UK wardrobe with the CCBMs. There was variation in the level of reduction between CCBMs and between environmental impact indicators. Online resale showed the greatest reduction but the reduction was not significantly greater than other resale business models. Displacement of new product sales was particularly important to the results.

Following a review, it was possible to improve upon previously existing data for clothing use, particularly clothing acquired using CCBMs in the UK. It was confirmed that CCBMs reduce the environmental impact of clothing relative to conventional, linear extraction, production and disposal of clothing. The results achieved depend upon a number of different factors and importantly include the ability of CCBMs to replace a proportion of linear sales.

5.04.P-Tu407 Methodological Updates in the Agricultural Sector in the Ecoinvent Database

Francesco Cirone*, Andreas Giakoumatos and Simone Fazio, ecoinvent, Switzerland*

Ecoinvent is a comprehensive LCI database that provides reliable and transparent information on the environmental impacts of products and services. Recently several changes have been made in format, content, LCIA methods, and sector-specific methodological improvements. Within them, relevant updates are implemented for the ‘Agriculture, Fishery and Animal Husbandry’ sector to increase transparency and precision of data. The methodological changes need to overcome the following issues:

- Use of fuels in Agriculture: Fuels were previously modelled together with the whole agricultural operations, with a pre-defined fuel consumption per hectare. When the consumption declared by the data provider was different, the whole operation was upscaled or downscaled accordingly. In the new approach, the fuel is inventoried separately, but always linked to the specific operation, which will be kept as a fixed amount of one or multiple (in case of multiple passes) hectare(s)
- Remodelling of Pesticide emissions: Emissions were previously reported as 100% emissions to soil. The new approach adopts Pest-LCI model to estimate emissions in different compartments (soil, air, and water). The emissions to crop have not been modelled, since the crop compartment belongs to Technosphere, and the related emissions are allocated to soil (in line with PEF or SALCA)
- Split of Multi-nutrient fertilizers (MNFs): MNFs were modelled as whole fertilizer, leading to potential partial double counting or underestimation for some of the single nutrients. The new approach adopts a pre-modelled split of the single nutrient contribution, also including a specific split of emissions in the production phase, where applicable. It includes a recalculation of the market(s) for fertilisers, where used, to rebalance shares of different nutrients where specific products are considered in more than one market and the quantities (e.g. N and P2O5 from ammonium phosphate) are not properly balanced according to the quantity of nutrients’ supply from different components.

The applied changes lead to changes in LCIA results for fuels and multi-nutrient fertilizer (the latter a bit more variable), the overall score changes due to pesticide remodelling are also low, but with a different distribution of toxicities according to the different compartments.

5.04.P Advancements in Life-Cycle Inventory (LCI): Enhancing Data Collection and Management, and Addressing Temporal Aspects

5.04.P-Tu401 From Aggregated Data to Urban Building Energy Models to Assess Priorities in Buildings Refurbishment Actions

Antonino Marvuglia *and Mohamed Laib, Luxembourg Institute of Science and Technology (LIST), Luxembourg*

To help setting up priority actions for renovation at city level, comprehensive building energy models are and will be increasingly needed. Building energy modelling can be divided into simulation (engineering), data-driven and hybrid approaches. Simulation models allow high prediction accuracy but require detailed data about the building (geometry, materials, renovation state, occupancy, etc.). Moreover, they are time-consuming and computation resources intensive, especially when the objective is assessing a large set of buildings. To circumvent these shortcomings, many studies use data-driven surrogate models for energy use prediction in large-scale renovation and design projects. These models require fewer details at the building level because they rely on a simplified representation of the buildings, but necessitate large data sets.

In our study, which is related to the city of Esch sur Alzette (south of Luxembourg), we started from aggregated gas consumption data available at the district level (including only residential buildings) and, by using building-related data and information (year of construction, building archetype, building volume and heated surface, estimated occupancy, and for some buildings also roof and walls U-values and type of windows and boiler system installed) as weighting factors, we used mathematical optimization to allocate the aggregated consumption to the building level. The optimization was performed using the scipy.optimize.minimize function of the SciPy Phyton library, and the objective function to minimize was the difference between the measured aggregated gas consumption data (district scale) and the sum of the allocated (disaggregated) building consumption at building scale. This allowed to create a training and a test set used to train an extreme learning machine (which is a fast and efficient single-layer feedforward neural network) that we then used as surrogate model to predict the expected energy use intensity (i.e. energy used by m2 of building heated area) and consequent emission savings of each building under scenarios of future renovation that we designed in previous work conducted on the same city. An estimation of the renovation costs was obtained using a simplified cost calculation procedure relying on cost data published by previous studies, that yielded actualized costs ranging from about 200 /m2 to above 1000 /m2 depending on the type of renovation simulated.

Disclaimer/Disclosure: This study has received funding from the Luxembourg National Research Fund (FNR) under the project CHIASMUS (grant n. INTER/FNRS/23/18290291).

5.04.P-Tu402 Evaluation of the Environmental Aspects of Running a Wind-PV Hybrid Park in Terms of Temporal Resolution of Energy Supply and Grid Connection Capacity

Raphael Schauer[1], Martin Ofner[1], Gerhard Piringer[1], ***Doris Rixrath[2]*** *and Eva-Maria Wiener[1], (1)Hochschule fur Angewandte Wissenschaften Burgenland GmbH, Austria, (2)JRZ LiSA, University of Applied Sciences Burgenland, Austria*

Renewable energy integration is crucial for decarbonizing the energy sector. This study examines the annual utilization of a photovoltaic (PV) and wind hybrid park in Schattendorf, Austria. During episodes of simultaneous high wind and solar availability, the existing grid connection capacity limits grid feed-in and currently forces curtailments of the wind turbine or PV output. This results in a loss of renewable energy of approximately 20 MWh or 0,1 % of the total wind output of this hybrid park. This study will assess several scenarios with the aim to environmentally optimize the temporal management of hybrid parks. Two key questions are addressed:

1. By how much can environmental impacts be reduced by using a storage system that shifts the surplus electricity to hours with a higher proportion of fossil fuels in the grid mix?
2. What ecological benefits can be gained when the excess energy is instead fully integrated into the Austrian grid by extending the grid connection capacity?

The core challenge lies in balancing energy supply with the grid connection capacity without sacrificing potential renewable output. For the assessment LCI-data in a similar temporal resolution is necessary. So our approach combines empirical data from on-site measurements, calculated performance metrics, and publicly available data on energy mixes to analyze the extent of energy loss and explore mitigation strategies.

Methodologically, the study employs data analysis, scenario modeling, and storage simulations to determine the optimal conditions for enhanced energy storage and utilization. Data will be evaluated with an hourly resolution.

Preliminary results suggest a substantial reduction potential for climate change impacts if curtailments could be minimized or avoided. Results will compare the environmental impacts of various utilization scenarios, analyze the contributions of various system components and of the turbine lifetime. In a sensitivity analysis, the effect of battery size will be explored and simulations will be conducted to determine the optimal storage capacity.
The findings contribute to advancing flexible supply and demand solutions within the energy sector, offering practical insights into how hybrid parks can optimize renewable energy contributions under grid constraints. This research provides valuable case study data for policymakers and energy planners aiming to enhance the resilience and sustainability by better integrating hybrid renewable sources.

Disclaimer/Disclosure: This work was supported by the Josef Ressel Centre for Linked System Assessment to Support Sustainable Energy Supplies - LiSA, Department of Energy and Environment, University of Applied Sciences Burgenland. The authors gratefully acknowledge the financial support provided by the Austrian Federal Ministry of Labour and Economy, the National Foundation for Research, Technology and Development, and the Christian Doppler Research Association.

5.04.P-Tu403 Challenges on the Upscaling of Self-Assembled Monolayer Used in Perovskite PV from a LCA Perspective

***Afzal khan Peerukhan**, Roberto Magnifico and Angelique Leonard, University of Liège, Belgium*

In the last decade, Self-Assembled Monolayers have become highly effective interfacial layers for perovskite PV devices because of their prime role in enhancing device efficiency, stability, and charge extraction. SAMs are single-molecule-thick films that spontaneously organize on surfaces through molecular self-assembly, offering a precise way to tune surface chemistry and energy alignment.

Among various SAM materials, MeO-2PACZ and MeO-4PACZ are the two compounds that have demonstrated significant potential for use in perovskite PV. Despite these advancements, there are significant challenges to the upscale of SAMs data, particularly from a life cycle assessment (LCA) perspective. On a lab scale, the synthesis of SAM molecules often involves complex, multi-step organic chemistry that requires high-purity reagents and large volumes of solvents and energy consumption leading to increased environmental impact. Laboratory conditions are not optimized for better materials and energy efficiency, making it difficult to scale up parameters like energy use and emissions accurately. The upscaling process introduces uncertainties and requires careful assumptions about process efficiencies and supply chain factors. Despite these challenges, upscaling is essential to mimic real-world industrial settings and ensure that LCA results reflect the true impacts of large-scale production.

In short, key challenges for the upscaling of LCI data, are inadequate inventory data and data quality, material input, energy consumption, process yield, and finally waste generation and management at end of life. This study provides a comprehensive comparison of the lab and industrial scale LCA of MeO-2PACZ and MeO-4PACZ used in perovskite PVs. It examines the LCA implications of upscaling of MeO-2PACZ and MeO-4PACZ production and highlights environmental Impacts. This study also provides a correlation between lab-scale and industrial scale data, facilitating upscaling efforts of similar chemicals when industrial data is not available. Primary data have been gathered from project partners, supplemented by secondary data from Ecoinvent v3.9.1. The LCA study is done according to the ISO 14040/44 standards.

5.04.P-Tu404 Using Geography in LCI collection: An LCA Model to Assess the European Wind Turbine Fleet

***Dominik Huber** and Maeva Lavigne Philippot, Vrije Universiteit Brussel, Belgium*

Various LCA models exist for the evaluation of wind power, all taking into account, to some extent, spatially refined LCI data. A model capable of evaluating the environmental impact of potential wind turbines in Europe is currently lacking, due to this large scope coming along with extensive data. Thus, we present a new LCA model that considers turbines location all over Europe scalable to its rated power to produce spatially differentiated results.
We build on WIND_LCA_DK, an open-source model developed to assess the Danish wind turbine fleet and further develop it to assess wind turbines on the European continent. While the model is capable of scaling the LCI to the rated power, in the case study, 3.4MW onshore turbines are investigated for installations in France, Italy, Norway, and Germany. First, the location (longitude/latitude) is added as an argument to determine the LCI data of a single turbine. The location data is then used to obtain the following LCI data: a) the type of foundation (offshore/onshore), b) the type of foundation including their material for different foundation types based on the sea depth, c) the produced electricity of the turbine and d) the ISO country code to identify relevant ecoinvent processes, cable length for grid connection and

transportation distances.
The French wind turbine has, with 24 gCO2eq/kWh, the highest climate change impact (CC), whereas the other turbines result in between 17 and 18 gCO2eq/kWh. As the rated power of all wind turbines is 3.4MW, the French turbine yields the lowest production and the CC of the French electricity mix is low, the CC difference can be attributed to adjusted cable length or transportation distances.
The LCI collection is enhanced by data from geographical sources, e.g., transportation distan ce, connection cable length and sea depth. The modelled case study results in different environmental performances depending on their location, which can be linked to improved LCI collection.

5.04.P-Tu405 Powering the Future: Integrating Battery Degradation into Battery Life Cycle Assessment

***Zhi Cao**, Xin Chen and Chunli Chu, Nankai University, China (Mainland)*

Achieving a sustainable low-carbon transition via electric vehicles hinges on a thorough understanding of the carbon footprint of lithium-ion batteries, especially during their use phase. This aspect is often neglected due to the varied battery application scenarios and the inherent uncertainty and complexity associated with battery service life. Factors such as battery efficiency and degradation are crucial in determining the indirect greenhouse gas (GHG) emissions during this phase. Therefore, integrating a battery degradation model into the use phase assessment is vital for a more prec ise evaluation of the carbon footprint.

In this project, we develop a comprehensive model that integrates the battery lifetime model within a life cycle assessment (LCA) framework. This model will estimate both cradle-to-gate and use phase GHG emissions for five battery chemistries: LFP, NCA, LMO, NMC111, and NMC811. We aim to examine how regional differences in user charging habits and ambient temperatures affect battery durability and subsequently influence GHG emissions. Moreover, we will quantify the impacts of battery efficiency and user charging habits on the GHG emissions across different life stages of the battery, employing sensitivity analysis to deepen our understanding of the relationship between battery performance, usage patterns, and GHG emissions.

We aim to address the following research questions: (1) What are the GHG emissions of different battery chemistries in relation to their durability? (2) How does battery efficiency impact GHG emissions during the use phase? (3) How do variations in battery durability, influenced by different usage scenarios, affect both cradle-to-gate and use phase GHG emissions? This project provides detailed insights into the life cycle emissions of batteries and offers guidance on optimizing battery usage to minimize GHG emissions.

5.04.P-Tu406 A Novel Tool for Generating Hybrid LCA Databases

***Michael Philipp Weinold**[1], Guillaume Majeau-Bettez[2] and Tapajyoti Ghosh[3], (1)Paul Scherrer Institute (PSI)/ETH Zurich, Switzerland, (2)Chemical Engineering, Polytechnique Montreal, Canada, (3)NREL, United States*

We present a novel open-source tool for generating hybrid life-cycle assessment databases. To showcase the utility of this software, we present LCA results based on two hybrid databases generated by combining the USEEIO/USLCI and Exiobase/Ecoinvent databases. We show that the environmental impact of production processes ("activities") changes significantly through hybridization - as additional inputs from the input-output sectors are added through upstream connections. Changes are up to 100% for multiple impact categories.

While hybrid life-cycle assessment has long been known to improve the accuracy of environmental impact assessment, a lack of tools for hybridizing databases has been cited by all recent reviews as a key reason hampering the adoption of the method by practitioners. A first open-source package named "pyLCAIO" by Agez (Polytechnique Montreal) was first released in 2020, but this tool was intended to hybridize specific versions of specific databases only. In contrast, our tools allows practitioners a maximum amount of flexibility - with regards to databases, input data and output data.

To our knowledge, this is the first time, hybridization of multiple databases has been made possible to users. We are confident that our tool and our hybridization results will be interesting to a broad audience - both LCA practitioners and sustainability researchers more broadly.

5.04.P-Tu407 Methodological Updates in the Agricultural Sector in the Ecoinvent Database

***Francesco Cirone**, Andreas Giakoumatos and Simone Fazio, ecoinvent, Switzerland*

Ecoinvent is a comprehensive LCI database that provides reliable and transparent information on the environmental impacts of products and services. Recently several changes have been made in format, content, LCIA methods, and sector-specific methodological improvements. Within them, relevant updates are implemented for the 'Agriculture, Fishery and Animal Husbandry' sector to increase transparency and precision of data. The methodological changes need to overcome the following issues:

- Use of fuels in Agriculture: Fuels were previously modelled together with the whole agricultural operations, with a pre-defined fuel consumption per hectare. When the consumption declared by the data provider was different, the whole operation was upscaled or downscaled accordingly. In the new approach, the fuel is inventoried separately, but always linked to the specific operation, which will be kept as a fixed amount of one or multiple (in case of multiple passes) hectare(s)
- Remodelling of Pesticide emissions: Emissions were previously reported as 100% emissions to soil. The new approach adopts Pest-LCI model to estimate emissions in different compartments (soil, air, and water). The emissions to crop have not been modelled, since the crop compartment belongs to Technosphere, and the related emissions are allocated to soil (in line with PEF or SALCA)
- Split of Multi-nutrient fertilizers (MNFs): MNFs were modelled as whole fertilizer, leading to potential partial double counting or underestimation for some of the single nutrients. The new approach adopts a pre-modelled split of the single nutrient contribution, also including a specific split of emissions in the production phase, where applicable. It includes a recalculation of the market(s) for fertilisers, where used, to rebalance shares of different nutrients where specific products are considered in more than one market and the quantities (e.g. N and P2O5 from ammonium phosphate) are not properly balanced according to the quantity of nutrients' supply from different components.

The applied changes lead to changes in LCIA results for fuels and multi-nutrient fertilizer (the latter a bit more variable), the overall score changes due to pesticide remodelling are also low, but with a different distribution of toxicities according to the different compartments.

5.04.P-Tu408 Identifying Key Predictors for Biodiversity, Water and Climate Footprints of Crop Production

Farhang Raymand[1]*, Koen Kuipers*[1]*, Sarah Sim*[2]*, P. James Joyce*[2]*, Aafke Schipper*[1] *and Mark Huijbregts*[1]*,*
(1) Radboud University, Netherlands, (2) Unilever, United Kingdom

Crop production is one of the key drivers of greenhouse gas (GHG) emissions, land and water use globally. Life cycle assessment of these (and other) environmental impacts for crop-location-management practice combinations is highly relevant for understanding the magnitude of impacts and for exploring potential mitigation options. However, primary farm-level data are difficult to gather and secondary datasets (life cycle inventories; LCIs) are missing for many crop species, farming practices and regions. As LCI data gaps are manifold, it is necessary to prioritize data compilation efforts, focusing on the inventory flows that contribute most to environmental impacts. Here, we identify the most important LCI input flows, up to the farm gate, in terms of their contributions to biodiversity loss, water use and GHG emissions. To that end, we model these three environmental footprints for 92 crops across 44 regions based on Ecoinvent and Agribalyse LCI data and using the ReCiPe2016 impact assessment methodology. Subsequently, we apply five modelling techniques (Random Forest, K-Nearest Neighbors, Artificial Neural Network, Generalized Boosting Method, and Linear Modeling) to predict the life cycle footprints based on 27 groups of farming inputs, including fertilizer application, pesticide use, tillage, and yield. We find that the Generalized Boosting Method outperforms other modelling techniques when using all 27 predictors, achieving a cross-validated explained variance of 84-88% for the three environmental footprints. Random Forest performs best when lowering the number of predictors to less than ten. A Random Forest model with seven predictors achieves a cross-validated explained variance of 81-88%. Key predictors of biodiversity footprints are yield and fertilizer input. For water footprints, irrigation, fuel input, and pesticide input are the most important. GHG footprints are mostly related to yield, fuel, heat, electricity and fertilizer input. Our study offers a systematic approach to identify key predictors of crop production impacts, facilitating targeted crop LCI gap-filling.

5.04.P-Tu410 Ensuring Environmental Integrity: A Critical Assessment of Mass Balance in Food Packaging LCA

Musharof Khan*, Katri Leino and Juha-Matti Katajajuuri, Natural Resources Institute, Finland*

The mass balance approach is a chain of custody model used in a variety of industries that allows for the mixing of sustainable and non-sustainable materials. This approach is based on established standards and auditable bookkeeping. However, the mass balance approach has some limitations. The problem with mass balance is that it does not reflect the physical properties of the material or ensure physical traceability. Nevertheless, it is not suitable for all types of materials. For example, it cannot be used for complex materials such as plastic waste, which contains a mixture of different polymers. In these cases, other methods, such as carbon counting or net calorific value, must be used to determine the chemical value of the recycled feedstock. In mass balance the calculations are not based on the physical relationship between the input resources and final product content, meaning e.g. that a product might be sold as biobased but still contains only 5 % biobased materials. Even though, there are existing mass balance certification systems and mass balanced products already in the markets, there is no established and regulated market for products attributed materials, and ensuring no double-counting or green washing exists is difficult. Additionally, the LCA standards and PEF do not address the mass balance approach, and there are no clear guidelines on how to use mass balance in LCA. This makes it difficult to assess the environmental impact of products that use the mass balance approach. In this case, how to consider mass balance in a national PEF-wise guidance for LCA of food packaging? To address these issues, there is a clear need for a standardized methodology for conducting Food Packaging LCA studies that aligns with the PEF framework. This methodology should provide specific instructions on how to account for the environmental impact of products made from different materials with different attributable properties, coming from various sources. By developing and implementing such a standardized approach, companies can more accurately communicate the environmental performance of their products to consumers.

Disclaimer/Disclosure: This work is part of LIFE-IPE-FI-PlastLife co-funded by European Union. Gemini developed by Google DeepMind was used for grammatical check and language improving.

5.04.P-Tu411 Transforming LCI Data for Plastic Packaging Using LLMs: A Path Toward Greater Accuracy, Transparency, and Efficiency

*Huimin Chang, **Jiayi Yuan**, Ming XU, Jinliang Xie, Chuke Chen, Nan Li, Wenjie Shi, Hang Yang and Si Zhang, Tsinghua University, China (Mainland)*

Life Cycle Inventory (LCI) data is essential for Life Cycle Assessment (LCA), particularly in calculating Global Warming Potential (GWP) under the European Union s Product Environmental Footprint (PEF) initiative. By providing consistent and transparent environmental metrics, LCI data helps identify environmental hotspots, supports sustainability assessments, and guides businesses and policymakers toward more sustainable products and processes.

Despite its importance, LCI datasets face significant challenges that limit their reliability and usability. Issues such as data inaccuracies, methodological inconsistencies, and limited documentation hinder the verification and reproducibility of results. Many datasets are also outdated, unable to keep up with technological advances and market dynamics, further compromising their relevance. Moreover, collecting and updating high-quality LCI data is resource-intensive, requiring expertise and significant effort to address regional and sectoral variations and the dynamic nature of industrial processes.

To overcome these challenges, we propose a novel framework that utilizes large language models (LLMs) to automate key aspects of LCI data management, including data extraction, validation, and synthesis. By leveraging LLMs, this approach reduces processing time, minimizes human error, and improves data comprehensiveness. Focusing on plastic packaging one of the most environmentally impactful product categories the framework enhances transparency, timeliness, and granularity. This method addresses critical gaps in LCI data while offering practical insights to advance sustainability practices and meet stringent environmental standards.

5.04.P-Tu412 Advancing Plastic Modelling Methods in Life Cycle Assessment

***Heather Margaret Logan, PhD Candidate** and Anders Damgaard Pr, Technical University of Denmark, Denmark*

Plastics are versatile and complex materials made of chemicals, known as additives, and polymers. The combination of polymers and additives is what makes plastics multi functional across so many applications and industries. Due to the variety in the potential material composition, material flow-analyses (MFA) and life cycle assessments (LCA) of plastics often omit plastics additives from the scope of their study or aggregate them. However, such approaches lead to underestimations of the potential risk cycling, contamination, degradation, and byproducts which result from the behaviour of additives throughout the lifecycles, recycling, and management (or lack of management) of plastics. These oversights may lead to underestimation, generalizations, or omissions of the toxicity potential of plastics both in their linear lifecycle studies and anticipatory circular lifecycle studies.

Moreover, the lack of available data, transparency, and reporting on the quality of and type of additives included in plastics has previously made including additives in MFAs and LCAs difficult, without close shareholder collaboration. Fortunately, researchers across the globe have worked to provide significant insight into the chemicals associated with the production of plastics. In previous research we have mapped this data to LCA data availability. In this study we have mapped the chemicals associated with the production of plastics to impact methods and characterization factors. We have then created a python package to simulate the chemical and polymer composition of plastics (potential or matched to user input) to available LCA data, allow the user to select close proxies or assemble additive portfolios for unmatched chemicals, and score the completeness and data quality of the flows included in the mixture. These portfolios can be used by the LCA practitioner to create better models of plastics in LCAs and assess which databases provide the best available data for the plastic under study. The package then allows the user to either export the data as an excel to use when modelling in their chosen software or can be linked to Brightway.

This package is then used to model and demonstrate how to include additives in LCAs of plastics in various end of life and waste management pathways for a case study of cosmetic packaging can help to assess the potential additive contamination, degradation rates, virgin additive needs in multiple loop life cycles for plastic materials.

Disclaimer/Disclosure: This project has been funded as a part of the Circularity of Industrial Thermoplastic for high quality recycling (C-FIT) project through TRACE: A Transition Towards Circular Economy which is a partnership funded by Innovation Fund Denmark and the European Union: NextGenerationEU.

5.04.P-Tu413 Prospective LCA of Road Transport across Various Powertrain Options

***Aleš Paulu**, UCT Prague, Czech Republic*

As the transportation sector aims for rapid transformation toward sustainable mobility, understanding the environmental impacts of various powertrain technologies is crucial. This study presents a prospective life-cycle assessment (LCA) of diverse road transportation options, including cars, light commercial vehicles, heavy-duty trucks, and buses, across various powertrain configurations: internal combustion engine (diesel, petrol, and compressed natural gas), battery electric, plug-in hybrid, and fuel cell electric. Designed to reflect average European conditions, the analysis draws primary data from an extensive literature review and laboratory measurements, ensuring robust and representative inputs for each powertrain and vehicle type. The analysis is further distinguished in leveraging prospective LCA through coupling background databases with projections from Integrated Assessment Models (IAMs), to assess potential future environmental impacts of each individual powertrain option. By incorporating IAM predictions, this LCA not only provides insights into current environmental burdens but also explores their evolution under different technological and policy scenarios. The findings aim to guide stakeholders in making informed decisions on sustainable transportation solutions by highlighting the varying environmental impacts over time of different vehicle and powertrain combinations. This research thus contributes to advancing transportation LCA methodologies and aligns with global efforts to minimize environmental footprints in the mobility sector.

Disclaimer/Disclosure: Supported by the grant no. CK04000045 of the Technology Agency of the Czech Republic

5.04.P-Tu415 Progress of Carbon Intensity of Fossil Fuels in Brazil

***Anna Mourad** and Joaquim Seabra, State University of Campinas (UNICAMP), Brazil*

Several actions have been carried out in the transportation sector to support the energy transition, preparing the current energy systems for a market less dependent on fossil fuels. RenovaBio is a Brazilian program that encourages the increasing introduction of renewable fuels, through a program of carbon credits, acquired by comparison with the fossil fuels they are replacing. For this reason, the objective of this paper is to update the emissions estimate for the production of gasoline and diesel used as a reference in RenovaBio. The development of this work was based on the well-to-wheel life-cycle assessment methodology, focused on carbon intensity (CI). Given that Petrobras is responsible for 88% of oil, 83% of gasoline, and 88% of diesel productions in the country, a "top/down" approach was adopted using its results from public data available in company sustainability reports audited by a third party and statistical sector publications. To calculate the CIs, the imported portions of oil and ready-made fuels were considered, adding the specific carbon emission from each country as well as the from transportation using factors from Ecoinvent 3.9. Refining emissions were estimated by combining the individual production of each of the 10 refineries of the Petrobras group along with simple energy allocation applied for the various co-products. The results obtained show a reduction in carbon intensity of 4% found for both fuels in the period from 2010 to 2023, reaching values of 82.8 and 87.2 gCO2e/MJ for gasoline and diesel, respectively. However, when only the E&P, transportation and refining stages are considered, the reduction achieved is 33.5%.This improvement in fossil fuel production efficiency can be partially explained by the high share of oil coming from the sea (97.7%) through modern extraction technologies in deep and ultra-deep waters, which has much smaller environmental impacts than other technologies. Furthermore, Petrobras, which has been complying with its strategic plan to reduce these emissions, has implemented several improvements to reduce the burning of gases in the flare, the energy consumption in refineries, and the losses, among other actions. Comparing the CIs obtained in the present study for the reference year of 2010, Brazilian fuels already had lower emissions of gasoline (14 and 9%) and diesel (10 and 4%) than those of the Low Carbon Fuel Standard of California and the Renewable European Directive, respectively.

5.04.P-Tu416 A Critical Analysis of EF's Carbon Footprint Formula in the Context of Food Packaging LCA

***Katri Leino**, Musharof Khan and Hannele Heusala, Natural Resources Institute Finland (Luke), Finland*

There has been long a debate and different practices on interpreting the ISO14044 s recommendations on multifunctionality problems in life cycle assessment (LCA) and whether system expansion can be used in attributional LCA (ALCA) or should it be considered consequential LCA (CLCA). Traditionally ALCA has been used for product footprints and CLCA to model impact of marginal changes to guide e.g. decision making. The approaches are mixed in some established assessment methods, e.g. environmental product declarations allow for credits from End-of-Life (EoL) declared as additional information. The European Commission s Environmental Footprint (EF) method is also mixing the approaches as the Circular Footprint Formula (CFF) addressing the EoL modelling has consequential parts. Using different approaches in modelling different parts of the life cycle can be considered illogical. Methods used in LCAs targeted to external communication should be harmonized and consistent, leaving no room for different assumptions.

Recyclability is one key aspect in the sustainability of packaging materials, but difficult to include in strictly attributional approach. Therefore for packaging materials it has been common to use system expansion to avoid allocation or to include credits from avoided burdens from EoL to the packaging material s footprint. This has a significant impact on the results and leads to situations with different assumptions on the substitutions making comparisons difficult. The EF s CFF formula is trying to depict the environmental benefits of recyclability. However, one major consequence of using the CFF formula is the risk of double counting. In case e.g. a packaging material is credited for incineration, this should be considered also in the energy production as usually energy production considers waste as a burden-free input. This means that all environmental impacts related to energy production with waste should be recalculated to avoid double counting. This would be very laborious. Other options could be to use allocation to share the burdens between production systems. This would encourage the use of recycled materials in packaging, but it does not encourage recyclability at EoL. The aim of this study is to find based on literature and case studies the most suitable way to model the EoL of packaging materials in environmental footprints aimed for consumer communication. The aim is to develop a PCR for food packaging aligned with the EF method.

Disclaimer/Disclosure: PlastLIFE (LIFE21-IPE-FI-PlastLIFE) project is funded by EU LIFE.

5.04.P-Tu417 Evaluation of the Carbon Footprint of Ferroalloys used in Stainless Steel Manufacturing

***Neda Hashemi**[1], Lionel Fourdrinier[2] and Sandra Belboom[1], (1)HELMo Gramme, Computer Science & Bio Tech Research Unit, Belgium, (2)CRM Group - Metallurgical Research Center, Belgium*

Ferroalloys are iron-based alloys containing a high proportion of elements such as chromium, nickel, silicon, manganese, etc. They are mainly used by the metallurgical industries, particularly in the stainless steel manufacturing process. The production of ferroalloys is an energy-intensive industrial sector generating significant CO2 emissions, the main greenhouse gas (GHG). Therefore, it is crucial to evaluate these emissions and understand their origins to reduce the carbon footprint of ferroalloys, contributing to sustainability objectives and the optimisation of energy costs.
Life Cycle Assessment (LCA) is a key method for assessing the carbon footprint of ferroalloys. This study conducted an in-depth exploration of the energy consumption and carbon footprint associated with

ferroalloy production, drawing on various LCA literature sources. The obtained results were then compared to the database of the Gabi software (LCA for Experts 10.8).
The results showed that a set of parameters influences the carbon footprint of ferroalloys and these parameters vary depending on the type of ferroalloy. Therefore, for a downstream consumer, such as a steel manufacturer, it is difficult to directly assess the carbon footprint based only on the quantity of elements in the alloy, especially when the alloy comes from different suppliers located in various countries.
The origin of electricity plays a key role in the environmental impact of all ferroalloys: renewable electricity could significantly reduce CO2 emissions compared to coal-based electricity. For ferrochrome (FeCr), the type of furnace also has a large influence on the amount of energy consumed. In ferronickel (FeNi), a reduction in CO2 emissions is possible by comparing the ore type, the Ni content of the ore, as well as the allocation strategy. For ferrosilicon (FeSi), increasing the percentage of silicon (Si) directly affects both energy and non-energy consumption, consequently increasing CO2 emissions. In ferromanganese (FeMn), higher CO2 emissions were observed for FeMn with medium carbon content (<1.5%), which is produced from high carbon FeMn. LCAs carried out with the same assumptions for all ferroalloys showed an increase in the carbon footprint in the following order: FeMn < FeCr < FeSi < FeNi. This study highlighted all the key parameters for evaluating the carbon footprint of the mentioned ferroalloys for steel fabricators, all compiled in a single investigation.

5.05 Methodological Advancements in Life Cycle Assessment of Emerging Bio-Based Systems

5.05.T-01 Challenges in Substituting Fossil Products with Bio-based Alternatives

Ewa Katarzyna Lagodzka *and Massimo Pizzol, Life Cycle Sustainability, Department of Sustainability and Planning, Aalborg University, Denmark*

Bio-based products bring major environmental benefits in terms of improved sustainability, reduced dependence on non-renewable resources, and greater circularity. However, substituting fossil-based products with their bio-based alternatives presents several challenges, given the dissimilarities in material properties, regulatory constraints, and technical performances. These should be taken into account in Life Cycle Assessment studies comparing alternative bio- and fossil-based products. This study explores the challenges related to replacing fossil-based materials with bio-based alternatives in five key sectors: construction, packaging, textiles, chemicals, and woodworking. Using a mixed methods approach consisting of a review of scientific literature and surveys with stakeholders, the research identifies key technical, regulatory, and market-specific barriers to substituting fossil-based products with bio-based ones. The systematic review and analysis of 42 selected peer-reviewed articles reveal common challenges related to mechanical performance, durability, regulatory restrictions, and processing challenges. In the construction sector, for instance, bio-based materials like Cross Laminated Timber require additional treatments to improve fire resistance and durability. In the packaging sector, bio-based packaging faces issues concerning moisture resistance and high costs. In textiles, bio-based fibers show poor processability and durable performance, while in the chemical sector, feedstock availability is seasonal, which complicates substitution. In the woodworking sector, bio-based adhesives face challenges regarding mechanical strength and resistance to water. In addition, regional differences in regulations can further complicate the substitution. Based on these findings, recommendation are provided for carrying our LCA studies of bio-based products taking into account the specific substitutability conditions.

Disclaimer/Disclosure: The study is carried out within the LCA4BIO project funded by the European Union grant no. 101135371.

5.05.T-02 Tipping Points in Polymer Life Cycle Greenhouse Gas Emissions

Stuart Walker*, Rachael Rothman, Tony Ryan and Fanran Meng, (1)University of Sheffield, United Kingdom*

For decades polymers have offered a unique combination of low cost and high durability and are the material of choice for a huge range of applications. In the current energy system, such polymers require the combustion of fossil resources to provide process heat and electricity for manufacture and often release emissions from embodied resources at the end of life. Polymers which are biodegradable or based on biological feedstock avoid some of this resource use, but in some cases have greater energy input requirements than their fossil polymer equivalents. This work compares life cycle greenhouse gas emissions of pairs of fossil- and biologically-based polymers under various UK electricity, heat and end-of-life treatment scenarios between 2023 and 2050. As specific emissions from electricity and heat supply reduce over the period, life cycle emissions of all polymers fall. Polylactic Acid was found to already have lower emissions than polystyrene in some scenarios. Low-density polyethylene was found to have lower emissions than poly(butylene adipate-co-terephthalate) in all cases to 2040. Bio-based high density polyethylene was found to have lower emissions than its fossil equivalent after 2024, and bio-based polyethylene terephthalate after 2043, depending on energy and end-of-life scenarios. Identifying and acting on these tipping points offers a route to significant reductions in the emissions of polymers, and even suggests that polymers with net negative emissions can be manufactured by 2040, offering the possibility of greenhouse gas sequestration through polymers made from agricultural waste.

5.05.T-03 Upscaling Framework for Laboratory-Scale Life Cycle Assessment

Hanna Sofia Leiter[1]*, Daniela Groiss-Fuertner*[1]*, Franziska Hesser*[1]*, Christoph Unterweger*[1]*, Spyros N. Yannopoulos*[2]*, Nikolaos Samartzis*[2]*, Michail Athanasiou*[2]*, Athinais Mavrikaki*[2]*, Athanasios Masouras*[3]*, Dorela Hoxha*[3] *and Simon Jestin*[4]*, (1)Wood K plus, Austria, (2)Foundation for Research and Technology Hellas-Institute of Chemical Engineering Sciences (FORTH), Greece, (3)Pleione Energy Sa, Greece, (4)CANOE, Le Centre Technologique Nouvelle Aquitaine Composites & Materiaux Avances, B t CHEMINNOV ENSCBP, France*

Environmental issues that are discovered during laboratory-scale Life Cycle Assessment (LCA) in a research and development (R&D) project can be drivers of innovation aiming to reduce the environmental hotspots before industrialization. Production in R&D projects is mostly done on laboratory scale on technology readiness level (TRL) 3, with the aim to reach pre-industrial scale production on TRL 6. Most of the existing upscaling frameworks rely on data being available regarding industrial production processes, electricity requirements for the industrial equipment, and minimum and maximum throughput of the machines. To bridge the gap between laboratory scale and industrial scale production, a framework has been developed that focuses on expert participation by estimations and scenario development from technical partners and literature. The proposed upscaling framework consists of four consecutive steps: 1) scenario definition, 2) upscaling mechanisms, 3) estimation of upscaled production and 4) calculation of the potential environmental impact of the upscaled production. The framework includes scenarios for efficiency increase in equipment, increase in production and optimization of yield, as well as a sensitivity analysis. The framework is showcased using the laboratory scale production of bio-based electrodes intended for supercapacitor (SC) application. In the laboratory-scale LCA of the electrode electricity requirements during production represent the largest hotspot, being responsible for 65 % of the total CO2-eq emission. During laboratory-scale production, the individual additives and solvents have only a small influence on the environmental impact, whereas after upscaling CO2 and phosphoric acid represent the largest environmental hotspots. In total, the results of the upscaled production processes depict a potential reduction in Global Warming Potential (GWP) of up to 90 % compared to laboratory scale production. All scenarios show the drastic reduction of the environmental impacts when produced on a larger scale and how environmental hotspots are shifted away from electricity requirements towards materials, additive and solvent inputs. The proposed framework can be applied in R&D projects to guide technical experts in resource selection and optimization of production processes. It has proven valuable in anticipating the environmental burden and burden shifting associated with upscaling production.

5.05.T-04 Job Creation Potential Tool for Assessing Employment Opportunities in a Bio-Economy Context

Eduardo Entrena-Barbero[1]*, Maria Gallego*[1]*, Sara Lago-Olveira*[1]*, Lucia Garcia-Santos*[1]*, Nirvana angela Marting Vidaurre*[2] *and Thomas Schaubroeck*[2]*, (1)Contactica Innovation, Spain, (2)Luxembourg Institute of Science and Technology (LIST), Luxembourg*

Social Life Cycle Assessment (S-LCA) is a methodology employed to assess the social impacts of products and services throughout their life cycle. The UNEP/SETAC Life Cycle Initiative's guidelines on S-LCA, constitute the primary reference in the field. This methodology has a relative low level of mature, apart from presenting several gaps when it is referred to the consideration of addressing the particularities of Bio-based Systems (BbS).

Putting the focus on one of them, it was identified a lack of inclusion of key concepts related to bio-economy, such as employment opportunities. The latter is in relation to one of the European Union s Bioeconomy Strategy, which include the creation of jobs. Therefore, in response to the limited availability of quantitative social indicators, one standardized procedure has been proposed to be followed for the estimation of the Job Creation Potential (JCP).

The JCP is a social indicator that quantifies the total number of jobs that a product system can generate through the supply chain. In this sense, it represents the aggregation of jobs created internally (in-house)

and those created by additional upstream life cycle stages.
The inclusion of the JCP methodology in the S-LCA represents an important methodological advance for conducting S-LCA to BbS. In addition, an easy-to-use online tool in the form of an Excel file is expected to be applied in a series of 10 case studies from five bio-based sectors: (i) construction, (ii) pulp and paper, (iii) textiles, (iv) biochemicals and (v) woodworking. It is also expected that this online tool will be further refined by differentiating the jobs created not only according to their origin (in-house or upstream), but also according to their skill level (high-, medium- and low-skilled work) and gender (male or female). Thanks to the development of a methodology for estimating the potential jobs created, it was possible not only to extend the range of procedures for applying an S-LCA, but also to address some of the social concerns included in the main strategies at EU level for implementing a bioeconomy. Notwithstanding, it was recognized that the inclusion of job losses due to bio-based activities is important to obtain a complete and accurate picture of the employment situation. Consequently, it is important that future research focuses on developing a more complete methodology that accurately captures both job creation and job losses.

5.05.P-Tu421 Evaluation of the environmental impacts of three novel bio-based alternative solutions through a Life Cycle Assessment (LCA)

Carlos Bernárdez Casás *and Rocio Pena Rois, AIMEN Research Center, Spain*
GREEN-LOOP Project aims to transition to a more sustainable manufacturing system by developing a new series of innovative bio-based materials that can replace the common materials used in the market (petroleum-based ones). The project is focused on three different bio-value chains, demonstrating the potential of these new solutions to detect critical industrial needs and decrease their environmental impacts. During the first value chain (VC), the development of a bio-rubber with lignin additives from the paper industry will be studied. The use case of this VC is a multifunctional panel with new properties, such as the enhancement in flame retardant, or vibrating-dumping properties for the construction sector. The use of biodegradable bioplastics in bottle closures is the use case for the second VC. Inside the food and beverage sector, the objectives of these closures are the olive oil and limoncello bottles. Finally, the last VC will assess wood composites for application in different industrial sectors. The composites are made with bio-based materials and aim to substitute the conventional material in the manufacturing of components, as well as sliding bearings. One of the main motivations for GREEN-LOOP Project is to improve the mechanical, physical, and chemical properties of bio-based products to make them viable in comparison to traditional composites, ensuring a lower environmental impact. A LCA is carried out to evaluate the sustainability of the GREEN-LOOP s development. The LCA is focused on environmental impacts from the beginning of the value chain (raw materials extraction), considering the recyclability or the waste reduction. The main project allegations say that the bio-based solutions have competitive mechanical performance with a reduction in the environmental footprint. These results talk about the potential for the materials and play an important role in the shift toward more sustainable manufacturing, providing viable solutions for industrial sectors to know environmental laws and the demand from the consumers related to the bioproducts. In summary, GREEN-LOOP Project offers innovative alternatives to traditional materials, while reinforcing the economic benefits of circular economy approaches and ensuring sustainability throughout the product lifecycle. This initiative lays the foundations for the widespread use of bio-based materials in various industries, contributing to a more sustainable and resilient future.

Disclaimer/Disclosure: This GREEN-LOOP Project's abstract has received funding from the European Union's Horizon 2022 research and innovation programme under grant agreement No. 101057765

5.05.P-Tu424 Assessing Environmental Performance Improvements in Microalgae-based Products via the ALIGNED Framework

Mathias Gustavsen[1]*, Massimo Pizzol*[1] *and Luis Costa*[2]*, (1)Aalborg University, Denmark, (2)A4F, Portugal*
The bio-based industry is important in addressing global challenges such as climate change and resource

depletion. This study examines the environmental impact of a multi-product microalgae biorefinery producing omega-3-rich lipids for edible oils, protein for dietary supplements, and a protein-carbohydrate mix for animal feed. The aim of the study is to test and evaluate how the ALIGNED framework for the life cycle assessment (LCA) of bio-based products can be used in practice to assess and improve the environmental performance of microalgae cultivation and downstream processes through identifying and implementing alternatives with lower impact. The learnings shall be applicable beyond the single case to the broader microalgae aquaculture sector. Several methods and tools developed in the ALIGNED project framework were implemented, in particular the methods for prospective background modelling (LCI), the methods for biogenic carbon accounting (LCIA) and for uncertainty analysis (interpretation), and methods for data structure and input (LCI), among others. The study evaluates a base scenario alongside alternative scenarios, such as the integration of on-site photovoltaic energy supply. Prospective analyses are conducted to explore future scenarios using predictive models. This is especially relevant as the case study represents an emerging industry. Results of the specific case considered show that the cultivation process has the largest environmental impact compared to harvesting and biorefinery, electricity being the main contributor to this impact, along with carbon dioxide and nitrogen source supply. The ALIGNED framework has provided tools accessible to non-experts, although further work can still be done to enhance the accessibility and simplify the experience.

5.05.P-Tu426 Towards the Integration of Bioeconomy Constraints in Life Cycle Assessment
***Kíra Lancz**, Fabio Sporchia and Massimo Pizzol, Life Cycle Sustainability, Department of Sustainability and Planning, Aalborg University, Denmark*
The transition to an EU-level bioeconomy will induce a growing demand for biomass feedstocks. The extent to which the production of different biomass feedstock types can respond to the increased demand is limited by many factors. This leads to competition between sectors demanding the same, finite biomass feedstocks. Considering these constraints and competition when conducting a Life Cycle Assessment (LCA) of bio-based technologies is fundamental. We developed a framework that allows to construct marginal market mixes for bio-based products and feedstocks by adapting EU-wide data on biomass production and use for applications in LCA.
We use an EU JRC dataset on biomass production, supply, uses, and flows. The dataset allows for a comprehensive cross-sectoral representation of the EU bioeconomy. It provides detailed biomass flows linked via supply and use data across different sectors. The cross-sectoral mass-based data is used to investigate seven bioeconomy sectors and capture the indirect effects of the corresponding fossil sectors on their markets.
Through consequential LCA, using JRC-derived economic data and policy trends, we forecast the future development of the supply and identify the unconstrained production activities, those with the capacity to increase production that will respond to the increased demand. We then create new market activities that represent the projected share of these activities in the marginal mix for biomass feedstocks.
We represent the seven targeted sectors and the relevant marginal mixes in a matrix format which enables the integration of the proposed model with LCI databases, allowing to capture the competition for biomass between different bio- and non-bio sectors in LCA.
The framework allows to obtain more holistic assessment of the environmental impacts linked with the shift to bioeconomy by computing new marginal mixes that capture the indirect burdens of competing bio-based and fossil sectors. Further work will focus on expanding the framework beyond bio-based products.

Disclaimer/Disclosure: The study is carried out within the LCA4BIO project funded by the European Union grant no. 101135371.

5.05.P Methodological Advancements in Life Cycle Assessment of Emerging Bio-Based Systems

5.05.P-Tu418 More Than Just Business: The Bioeconomy Supporting the Development of New Sustainable Business Models in Bulgaria
***Elena Gospodinova**, Darina Zaimova and Rosen Dimov, BUSINESS E-INCUBATOR GO-UP, Bulgaria*
Climate change and its inevitable cataclysms are no longer abstract theories. Just a few days ago, we said goodbye to the summer of 2024, which turned out to be the hottest in Europe since 1950. Temperatures were recorded 1.54°C above the seasonal average. Natural disasters affecting Bulgaria have become commonplace, and while the process cannot be stopped, it can be slowed down. This requires innovative solutions that can be integrated into the economy while also ensuring environmental and social protection. This study analyzes how the bioeconomy in Bulgaria stimulates the emergence of innovative business models based on the principles of sustainable development. Through an in-depth analysis of existing

initiatives and policies, the factors that facilitate or hinder the development of such models are identified. The study also analyzes the link between the bioeconomy and social innovation, examining examples of successful Bulgarian companies that have integrated sustainability into their business practices. In addition, the study will analyze the future prospects for the development of the bioeconomy in Bulgaria, the possible scenarios until 2030 and the barriers facing the business. The research will draw on surveys research and case study analysis of best practices and challenges.

Environmental sustainability and circularity criteria for industrial bio-based systems

5.05.P-Tu419 30 Years of Life Cycle Assessment (LCA) in Forestry: State of the Art and Methodological Proposal for the Life Cycle Assessment of Forest Operations

*Emina Mujevic[1], Franziska Hesser[2], Iris Kral[2] and **Martin Kuhmaier**[2], (1)FH Technikum Wien, Austria, (2)BOKU University, Austria*

Life cycle assessment (LCA) has been an important tool for assessing the environmental impact of various processes, products and industries since the late 1960s. In the early 1990s, LCA studies were started in the forestry sector, but these analyses lacked consistency and comparability. In 2015, a study by Klein et al. provided a detailed descriptive and quantitative analysis of existing LCA studies focusing on forest operations, with an emphasis on global warming potential (GWP). This work was the cornerstone for our study as it addressed issues such as study objectives, system boundaries, functional units, impact categories and processes involved. A decade later, our study aimed to assess progress in LCA of forestry production from 2013 to 2023 by analyzing recent LCA studies, comparing them with previous research, and updating methodological recommendations for conducting LCA in the forestry sector. Further objectives were to assess progress and remaining challenges in LCA of forest production over the last decade and to highlight the implications of recent LCA studies for policy decisions and sustainable forest management practices.

We analyzed 90 different peer-reviewed studies. The studies showed large differences between the methodological assumptions and the resulting outcomes. Most of the studies analyzed followed a cradle-to-gate approach, where two different system boundaries were identified: from forest to forest road and from forest to plant gate. Most studies investigated wood for energy purposes or as raw material for sawmills. We found many different functional units, expressed by dimension, by area and/or time, by mass or by energy content. A total of 14 impact categories were identified in our study, with global warming being the most frequently studied category. In half of all studies, allocation methods were not mentioned at all. In more than half of the studies, no methodological approach other than the IPCC Guidelines and the EN ISO 14040 and EN ISO 14044 standards was mentioned. If a database was used, ecoinvent was mentioned in most cases.

To enable better comparisons between LCA studies in the forest sector in the future, we propose some methodological approaches to harmonize system boundaries, functional units, considered processes and allocation assumptions or at least a more detailed metadata documentation. These proposals could help to clarify the description of forestry production in existing declarations and standards.

5.05.P-Tu420 Comparative Lifecycle Study of Wooden and Concrete Buildings in Finland: Advancing Holistic Sustainability Assessments

***Anni Vehola**, Elias Hurmekoski, Jaakko Jussila and Ritva Toivonen, (1)University of Helsinki, Finland*

The construction sector plays a crucial role in shaping global sustainability, contributing to both environmental challenges and positive impacts such as job creation and community well-being. While discussions around sustainable construction often focus on environmental impacts particularly carbon footprint a more comprehensive approach must also consider other key dimensions of sustainability. Therefore, this study examines the sustainability trade-offs and potential benefits of two identical multistorey buildings in Finland, one primarily constructed from wood and the other from concrete, using a comparative lifecycle assessment (LCA) approach that integrates both environmental and socioeconomic considerations.

The environmental LCA assesses impacts beyond carbon emissions across each lifecycle stage, from raw material extraction to end-of-life. To integrate socioeconomic considerations, a Social-LCA evaluates factors such as job creation, community benefits, and wellbeing of building users. This integrated approach facilitates a broader sustainability assessment, demonstrating that materials such as wood can offer notable socioeconomic benefits while also providing environmental advantages, alongside the trade-offs involved in material selection.

Preliminary results suggest that the wooden building may have a lower environmental footprint, particularly due to reduced fossil energy demands. Socioeconomically, wood construction shows potential for supporting local job markets and rural economic stability. However, both materials present distinct advantages and challenges, highlighting the importance of comprehensive assessments. By addressing these interconnected impacts, this study advances tools and methods for more comprehensive lifecycle assessments of bio-based systems, contributing to the refinement of sustainability frameworks. These insights are particularly relevant for policymakers and industry stakeholders navigating material choices to achieve decarbonization and broader sustainability goals.

5.05.P-Tu421 Evaluation of the Environmental Impacts of Three Novel Bio-Based Alternative Solutions through a Life Cycle Assessment (LCA)

Carlos Bernárdez Casás *and Rocio Pena Rois, AIMEN Research Center, Spain*

GREEN-LOOP Project aims to transition to a more sustainable manufacturing system by developing a new series of innovative bio-based materials that can replace the common materials used in the market (petroleum-based ones). 5.05.P-Tu422 Life Cycle Assessment Approaches and Applications to Emerging Bio-Based Technologies

***Narie Rinke Dias de Souza**[1], Lucia Garcia-Santos[2], Marcos Djun Barbosa Watanabe[1], Thomas Schaubroeck, PhD[3], Massimo Pizzol[4] and Francesco Cherubini[1], (1)NTNU, Norway, (2)Contactica, Spain, (3)Luxembourg Institute of Science and Technology (LIST), Luxembourg, (4)Aalborg University, Denmark*

Biomass is a promising renewable feedstock to replace conventional fossil-based products, especially in sectors that cannot be electrified such as production of chemicals, construction materials, textiles and intercontinental aviation and shipping. Some of the bio-based alternatives to replace fossil products are relatively new in the market with further improvement potential, while several highly promising options are at early stages of development (i.e., at a lab, pilot or demo scale). The application of life-cycle assessment (LCA) to emerging bio-based technologies is increasing but methodological gaps remain given their low technology readiness level (TRL). While LCA methods have been improved to estimate the environmental impacts of emerging bio-based technologies, challenges remain in ensuring the comparability and reproducibility of such assessments. This study reviews existing LCA studies, in general, and those of emerging bio-based technologies, in particular, dealing with scaling-up of technology maturity and with projection of background system to simulate industrial scale and future socioeconomic scenarios. We identified three main challenges after reviewing 120 articles: 1) Unclear and overlapping definitions, with use of neologisms such as ex-ante or prospective , without clear differentiation of technology maturity (e.g., TRL) from temporal position (e.g., present or future); 2) varying methods for scaling-up technologies from lab to commercial/industrial scale and for modifying future background economies; 3) lack of transparency when applying Integrated Assessment Models to transform datasets (e.g., premise or any other tool). Explicitly detailing the decisions and assumptions made during both scaling-up technology maturity and future projections is key for ensuring consistency, comparability and reproducibility in LCA results. To increase clarity, we understand prospective LCA as approaches estimating future changes in background and foreground systems, mainly driven by technology and socio-economic evolutions, while ex-ante can be better understood for low TRL systems that require scaling-up of technology maturity, but background processes are not necessarily modified.

5.05.P-Tu423 Assessing Regionalization of LCI Datasets of Fossil-Based and Biodegradable Bio-Based Polymers Used for Food Packaging in the European Context

Anna Carlesso, Lisa Pizzol, Antonio Marcomini and ***Elena Semenzin****, Ca' Foscari University of Venice, Italy*

As bio-based systems emerge as promising alternatives to FB counterparts for decarbonizing our economy, accurate LCA comparisons between fossil-based (FB) and bio-based (BB) polymers remain challenging. This study examines the influence of choosing generic versus country-specific Life Cycle Inventory (LCI) datasets on the impact assessment outcomes for key FB and BB polymers produced in Europe. Despite an increasing demand for regionalized data, site-specific datasets are often absent, and less representative generic datasets must be used. Moreover, although Europe has the greatest coverage of country-specific datasets, comparisons to generic datasets are limited in literature. The performed analysis used regionalized datasets for FB polymers (HDPE, LDPE, LLDPE, and PP) and BB polymers (PLA/starch, and TPS) from MLC Databases, applying the EF 3.1 method. Results were evaluated based on i) the occurrence of burden shifting from FB to BB polymers and ii) the influence of European country-specific datasets compared to generic (i.e., RER) datasets. Acidification and Eutrophication impact categories were found to increase in BB polymers, while a lack of standardized biogenic carbon accounting resulted to affect Climate Change assessment. Significant variations were found in Ionizing Radiation, Land Use, Ozone Depletion, and Water Use with no significant differences between FB and BB datasets. As main conclusions, the importance of regionalization in BB datasets was highlighted due to differing agricultural practices, and enhanced inventory and impact regionalization were recommended to capture regional dynamics accurately.

5.05.P-Tu424 Assessing Environmental Performance Improvements in Microalgae-based Products via the ALIGNED Framework

***Mathias Gustavsen**[1], Massimo Pizzol[1] and Luis Costa[2], (1)Aalborg University, Denmark, (2)A4F, Portugal*

The bio-based industry is important in addressing global challenges such as climate change and resource depletion. This study examines the environmental impact of a multi-product microalgae biorefinery producing omega-3-rich lipids for edible oils, protein for dietary supplements, and a protein-carbohydrate mix for animal feed. The aim of the study is to test and evaluate how the ALIGNED framework for the life cycle assessment (LCA) of bio-based products can be used in practice to assess and improve the environmental performance of microalgae cultivation and downstream processes through identifying and implementing alternatives with lower impact. The learnings shall be applicable beyond the single case to the broader microalgae aquaculture sector. Several methods and tools developed in the ALIGNED project framework were implemented, in particular the methods for prospective background modelling (LCI), the methods for biogenic carbon accounting (LCIA) and for uncertainty analysis (interpretation), and methods for data structure and input (LCI), among others. The study evaluates a base scenario alongside alternative scenarios, such as the integration of on-site photovoltaic energy supply. Prospective analyses are conducted to explore future scenarios using predictive models. This is especially relevant as the case study represents an emerging industry. Results of the specific case considered show that the cultivation process has the largest environmental impact compared to harvesting and biorefinery, electricity being the main contributor to this impact, along with carbon dioxide and nitrogen source supply. The ALIGNED framework has provided tools accessible to non-experts, although further work can still be done to enhance the accessibility and simplify the experience.

5.05.P-Tu425 Life Cycle Costing Tool for Assessing Economic Impacts of Bio-based Products and Systems

***Lucia Garcia-Santos**[1], Eduardo Entrena-Barbero[1], Sara Lago-Olveira[1], Maria Gallego[1], Thomas*

Schaubroeck, PhD[2] and Massimo Pizzol[3], (1)Contactica, Spain, (2)Luxembourg Institute of Science and Technology (LIST), Luxembourg, (3) Aalborg University, Denmark
Innovative Bio-based Systems (BbS) are set to play a role in reducing dependence on non-renewable resources, manage natural resources sustainably, mitigate and adapt to climate change, strengthen European competitiveness, scale up biobased sectors and unblock investments. However, when evaluating the substitution effects of this transition, current Life Cycle Sustainability Assessments (LCSA) often miss significant economic impacts when referring to BbS. The methodologies that are currently being developed mainly focus their economic assessment in industrial processes and their manufacturing stage, overlooking the costs of other relevant stages of a sustainability assessment such as the use phase or the end of life (EoL). Incorporating all the life cycle phases provides a better understanding of the economic benefits of transitioning from fossil-based to bio-based systems, facilitating easier comparisons between the two and allowing the inclusion of the economic assessment in the LCSA, marking a methodological advancement for conducting Life Cycle Costing (LCC) to BbS.

In this context, there is a need to integrate comprehensive economic indicators into LCSA frameworks to evaluate the total economic impact of a bio-based product or system over its entire life cycle. In addition, trade-offs in dynamic carbon storage considering GHG emission dynamics over time must be assessed and included in the economic evaluations. To address this issue, a selection and a harmonization of methods scientifically sound to assess LCC on BbS is performed to enable accurate evaluation of the potential economic impacts of bio-based products and technologies. LCC also enables the comparison of different production methods, feedstocks or EoL scenarios, optimising the economic impacts.

The development of the LCC user-friendly tool is underway though stakeholder engagement. Key stakeholders were identified and invited to participate in co-creation processes, ensuring that the resulting tools are accessible, and the indicators are appropriate and practical for end-users. This tool will form part of a broader suite designed to perform Life Cycle Sustainability Assessments (LCSA) for BbS.

Disclaimer/Disclosure: Acknowledgement This tool is an initiative from partners of the project LCA4BIO Harmonised Life Cycle Assessment methods for sustainable and circular BIObased systems No 101135371, funded by the European Commission.

5.05.P-Tu426 Towards the Integration of Bioeconomy Constraints in Life Cycle Assessment
***Kíra Lancz**, Fabio Sporchia and Massimo Pizzol, Aalborg University, Denmark*
The transition to an EU-level bioeconomy will induce a growing demand for biomass feedstocks. The extent to which the production of different biomass feedstock types can respond to the increased demand is limited by many factors. This leads to competition between sectors demanding the same, finite biomass feedstocks. Considering these constraints and competition when conducting a Life Cycle Assessment (LCA) of bio-based technologies is fundamental. We developed a framework that allows to construct marginal market mixes for bio-based products and feedstocks by adapting EU-wide data on biomass production and use for applications in LCA.

We use an EU JRC dataset on biomass production, supply, uses, and flows. The dataset allows for a comprehensive cross-sectoral representation of the EU bioeconomy. It provides detailed biomass flows linked via supply and use data across different sectors. The cross-sectoral mass-based data is used to investigate seven bioeconomy sectors and capture the indirect effects of the corresponding fossil sectors on their markets.

Through consequential LCA, using JRC-derived economic data and policy trends, we forecast the future development of the supply and identify the unconstrained production activities, those with the capacity to increase production that will respond to the increased demand. We then create new market activities that represent the projected share of these activities in the marginal mix for biomass feedstocks.

We represent the seven targeted sectors and the relevant marginal mixes in a matrix format which enables the integration of the proposed model with LCI databases, allowing to capture the competition for biomass between different bio- and non-bio sectors in LCA.

The framework allows to obtain more holistic assessment of the environmental impacts linked with the shift to bioeconomy by computing new marginal mixes that capture the indirect burdens of competing bio-based and fossil sectors. Further work will focus on expanding the framework beyond bio-based products.

Disclaimer/Disclosure: The study is carried out within the LCA4BIO project funded by the European Union grant no. 101135371.

5.05.P-Tu427 Density and Moisture Content Impact on the Environmental and Economic Performance of Woody Feedstock

Maxim Tschulkow *and Steven Van Passel, Department of Engineering Management, University of Antwerp & End-to-End lab of KU Leuven, Flanders Make at University of Antwerp, Belgium*
Background: Climate change is accelerating and our society is running out of time to stop us from exceeding our planetary boundaries and irreversible and dramatic consequences for life on our planet. Biomass is considered to be one of the solutions. Wood as a sustainable and regenerative source can be utilized for different applications within different bio-based sectors and technologies.
Challenge/problem statement: While the focus is usually on developing and optimizing novel emerging technologies, the woody feedstock and its environmental and economic implications are calculated very basic, potentially missing further optimization possibilities. The unique biological and physical characteristics of wood are often neglected. Particularly, the density and the moisture content of wood are very much species-specific affecting several (life cycle inventory) activities (e.g. drying, transportation, and process system engineering).
Method: Hence, the life cycle and techno-economic assessments are further extended by the dynamic density and moisture content model to account for feedstock-specific characteristics to further explore optimization potentials.
Results: The assessment shows that carbon emissions and costs decrease with increasing moisture content in feedstocks. Furthermore, the implications of higher moisture content on the performance of biorefineries were discussed, indicating that it has the potential to decrease carbon emissions and increase the economic feasibility of the biorefineries.
Summary and relevance: The newly developed extension enables to further optimize the utilization of feedstock by decreasing the cost and carbon emissions of feedstocks and biorefineries, giving the technology developers the option to develop technologies more flexibly.

5.05.P-Tu428 Towards Alternative Fertilising Products PEFCR: From Methodological Hotspots Identification to Industrial Case Studies Validation

Jorge Senan-Salinas[1]*, Miguel Montero Alonso*[1]*, Hannele Heusala*[2]*, Korkalo Pasi*[2]*, Karetta Vikki*[2]*, Carlos Alberto Torres*[1]*, Joan Colon*[1] *and Nancy Pena*[1]*, (1)BETA-UVIC, Spain, (2)LUKE, Finland*
Alternative fertilisers derived from secondary nutrient raw materials are pivotal for the Circular Economy while aligning with EU policies like Farm-to-Fork and new fertilising regulations. These products, sourced from agricultural, livestock, urban, and industrial waste, enhance Europe's economic resilience, promote resource efficiency, and support decarbonisation efforts. However, their environmental performance relative to mineral fertilisers remains uncertain due to the absence of standardised assessment frameworks.

The EU's Product Environmental Footprint (PEF) offers a harmonised Life Cycle Assessment (LCA)-based approach, yet no specific PEF Category Rules (PEFCR) exist for fertilisers, particularly bio-based alternatives. Addressing this gap, this work proposes a PEFCR-wise for alternative fertilisers. The process included an extensive literature review of LCAs, complemented by bilateral meetings with relevant stakeholders (fertiliser industry and JRC) and online surveys with industry leaders and practitioners. The proposed PEFCR-wise method was tested with data from 25 fertilising products derived from diverse raw materials such as blood, animal excreta, and agro-industrial waste. Preliminary results highlight key methodological challenges, including the selection of an appropriate functional unit (FU) and allocation rules. Stakeholders generally agree that relying solely on mass-based FUs is insufficient for fertiliser benchmarking, though no consensus on a universal FU has been reached.

To conclude, the first PEFCR for alternative fertilising products has been developed and applied to achieve the most suitable LCA methods for alternative fertilising products. Moreover, these methods were tested by a relevant share of the European fertilizer industry. Nonetheless, there are challenges mostly related to credits and burdens allocation along the supply chain, the precise responsibility splitting and the consequences of defining the feedstock as a waste or a product, and the emissions derived from the application technique or the multifunctionality in the supply of different nutrients by compound fertilisers.

5.05.P-Tu429 Assessing Environmental Impacts in Single Cell Protein Production: A Prospective LCA Approach

Eva Martínez-Ibáñez, *Maria Margallo, Jara Laso and Ruben Aldaco, University of Cantabria, Spain*

Transforming food production systems is essential to ensure that the use of natural resources and emissions remain within planetary boundaries. Innovative protein sources, such as Single Cell Protein (SCP) derived from the biomass of unicellular organisms, are emerging as promising solutions to address food scarcity and meet global nutritional needs. This study presents a prospective life cycle assessment (LCA) of different scenarios for SCP production using biogas derived from fish industry waste, with a focus on upscaling a lab-scale process. Four configurations were compared, exploring the recovery of heat, electricity, fertilizer, protein, and biomethane. The recovered materials and energy were included by expanding the system boundaries to account for avoided primary production, thus mitigating the environmental burdens associated with their production.

The results reveal significant differences in environmental impacts between laboratory-scale and industrial-scale processes. When upscaled, the environmental impacts were lower compared to other protein sources, highlighting the environmental benefits of protein derived from biomass cultivated with biomethane obtained through anaerobic digestion of fish industry by-products and waste. The baseline scenario showed the poorest environmental performance due to biogenic methane emissions from unutilized biogas. In contrast, modified scenarios incorporating various biomethane utilization pathways demonstrated substantial reductions in all impact categories. Among these, Scenario 3, which recirculated energy from cogeneration for internal use, showed the best environmental performance. Overall, the findings suggest that the optimal configuration combines biomethane, heat, and electricity recovery, providing valuable insights for further industrial-scale applications. Future challenges will focus on technical and economic feasibility, particularly in terms of technology readiness level, implementation, and investment.

5.06.P Including the Biogenic Carbon Emissions and Removals in Life Cycle Assessment: Advances and Challenges

5.06.P-We415 Biogenic Carbon Accounting and in Life Cycle Assessment of Single-Use Plastic Alternatives

*Jon McKechnie[1], Fanran Meng[2], **Stuart Walker**[2], Rachael Rothman[2], Experience Nduagu[3], Kirti Richa[4], Luis Sotomayor[3] and Timothee Roux[5], (1)University of Nottingham, United Kingdom, (2)University of Sheffield, United Kingdom, (3)ExxonMobil Technology and Engineering Company, United States, (4)ExxonMobil Technology Company, United States, (5)ExxonMobil Corporation, United States*

The shift from fossil-based plastics to bio-based alternatives raises important questions regarding the scale of alternative material demand and associated environmental impacts. This study aims to comprehensively evaluate the implications of increased demand for bio-based materials, initially focusing on paper and paper-based products in North America, arising from policies banning the use of single-use plastics. Through a critical review of single-use plastic policies and data on alternative material substitutions, we analyse market-driven demand for bio-based materials, estimating feedstock and land use requirements resulting from expanded production. We also assess existing policies on plastic ban and biogenic carbon accounting methodologies to identify potential advantages, trade-offs and unintended consequences. The study explores the current capabilities and limitations of life cycle assessment methodologies in capturing biogenic carbon impacts considered for the first time in relation to bio-based alternatives for single use plastics- through a case study of corrugated cardboard packaging product. Carbon flows are estimated based on a critical review of published studies and statistics pertaining to paper and cardboard production; product lifetime; end of life management; and retention of biogenic carbon within the product system via recycling. We apply a range of biogenic carbon assessment methodologies (0/0; -1/+1; dynamic; and GWPbio) to assess climate change impacts. Preliminary results provide insights into land requirements, greenhouse gas emissions, and key environmental indicators where notable differences may arise between fossil-based plastics and bio-based alternatives. The findings aim to support more informed policy development and decision-making regarding single-use plastic bans, laying the groundwork for broader assessments of other materials and regions in future research phases.

5.06.P-We416 From Macronutrient Content to Biogenic Carbon emission: Advancing Biogenic Carbon balance in Life Cycle Databases

Francesco Cirone, *Simone Fazio and Thomas Sonderegger, ecoinvent, Switzerland*
Biogenic carbon emissions and removals, encompassing carbon fluxes from biomass, land use and land-use change, and carbon storage in products, play a critical role in the global greenhouse gas (GHG) balance. These processes are vital for achieving climate mitigation targets, conserving biodiversity, and supporting renewable resource provision. However, integrating these dynamics into life cycle assessment (LCA) remains challenging due to gaps in standards, methods, and data, resulting in inconsistencies in modeling biogenic carbon flows. In this context, getting biogenic carbon properly balanced in the dataset (input-output) became a crucial point to improve biogenic carbonaccounting in LCA.
Ecoinvent is a worldwide established LCA database that accounts for around 20.000 datasets modelling human activities and processes and includes key sectors for biogenic products such as agriculture, forest, pulp, and paper. To quantify biogenic carbon in biomass growth, properties of elementary exchanges, Carbon dioxide, in air (resource from the air) which is the uptake by biomass growth, and Carbon dioxide, non-fossil as biogenic releases, are relevant. To improve biogenic carbon accounting in dataset harmonized modelling is needed in ecoinvent. The uptake should correspond to the carbon in products and byproducts leaving the process (for example, crop and straw) minus the carbon in relevant products entering the process (for example, seed and seedlings). Biogenic carbon of intermediate and elementary exchanges is quantified by the mathematical relation between dry mass and carbon content property. Dry mass quantification can be calculated using water or moisture content, while biogenic carbon by its average or specific percentage in lipids/proteins/carbohydrates/ash and fibre added as new properties in each specific exchange. Carbon in kg fixed in biomass can be estimated by multiplying the dry mass (in kg) by the carbon content (kg/kg).
Harmonized inventory for the bio-based (mainly agricultural) sectors in ecoinvent shows increased biogenic carbon accounting at the dataset and database level regarding carbon storage in biomass growth and significant variation in Carbon dioxide, in air and Carbon dioxide, non-fossil amounts for balancing.

5.06.P-We417 Investigating Approaches to Model LUC Impacts of EU Consumption
Valeria De Laurentiis[1], Taija Sinkko[2], Susanna Andreasi Bassi[1], Vasco Orza[2], Laura Garcia Herrero[1], ***Esther Sanye-Mengual***[2] *and Giulia Listorti[1], (1)European Commission, Joint Research Centre (JRC), Italy, (2)Piksel S.r.l., Italy*
The EU is a large importer of virtual land embodied in biobased commodities. As a consequence, EU consumption drives land use change (LUC) taking place overseas and is responsible for well-known related environmental pressures and impacts including deforestation, biodiversity loss, and contribution to climate change. The goal of this study is to investigate the influence of different calculation approaches and methodological choices on the assessment of the impact on Climate Change caused by LUC deriving from European consumption. To this end, it builds on a recently developed model that estimates the cropland, grassland and forest land embodied in EU consumption of biobased products, through a physical based accounting approach built on statistical data on production and trade of over 500 commodities. These virtual areas are then converted into emissions from LUC by means of statistical LUC (sLUC) approaches. Two different calculation approaches are used: the one outlined in the international standard PAS2050 and in the draft version of the GHG Protocol Land Sector and Removals Guidance.
A number of alternative methodological approaches are tested: when applying the PAS2050 two different approaches are used to calculate the average land use change associated to a crop (i.e. normal and weighted average taking into account the country s changes in land use categories), while in the approach proposed by the GHG Protocol two alternatives are used to allocate the national land use change to a crop (product expansion and shared responsibility) and two different time discounting approaches are applied (equal and linear). The resulting emissions are compared, and differences are discussed.
The present analysis is being conducted in the context of the update of the Environmental Footprint methods, the LCA impact assessment method recommended by the European Commission, for what concerns the modelling of emissions from land use change. Our analysis helps to shed light on the implications of these choices when using modelling results in support to policies. Due to its large scale and significance, our work is also relevant to support the design, development and implementation of future policies.

5.06.P-We418 A Time-Explicit Life Cycle Assessment of Woody Biomass Utilisation Scenarios in Switzerland
Arthur Jakobs, *Paul Scherrer Institute (PSI), Switzerland*
Holistically assessing the climate impacts of forest product utilisation is a complex endeavour, as it requires the integration of diverse and interdependent factors across spatial and temporal scales, from forest growth and disturbances influenced by changing climate scenarios to forest management practices that further determine the availability and characteristics of harvested wood as well as the change in the

forest carbon stock. Additionally, the end-use scenarios of wood products, encompassing potential carbon storage and substitution effects, must be evaluated in the context of a decarbonising economy. Addressing the multitude of these interconnections demands a comprehensive framework capable of capturing the full scope of the life cycle of a wood product, from carbon sequestration in the forests to the final release of the carbon, potentially decades.
We present a framework that combines forest management scenarios and dynamic material flow analysis to inform an Energy System model for Switzerland. This energy system model, in turn, is integrated with socioeconomic scenarios from Integrated Assessment Models to create prospective databases using Premise, that are subsequently used to perform time-explicit (dynamic prospective) life cycle assessments (LCAs) using bw_timex of various wood utilisation scenarios. This approach enables a detailed comparison of the opportunity costs of these scenarios, accounting for temporal storage, potential cascading uses of wood products, evolving background economies, and forest growth dynamics.
This study highlights the importance and challenges of coupling forest dynamics with downstream utilisation scenarios and broader economic contexts to evaluate the trade-offs and synergies in forest product utilisation. By addressing the temporal and systemic complexities, our framework advances the holistic assessment of forest-based bioeconomy strategies, offering a robust tool for assessing woody biomass utilisation.

5.06.P-We419 Comparison of Biomass-Based Synthetic Natural Gas Production Scenarios: Cradle to Gate Life Cycle Assessment
Diana Dimande*, Alexander Bartik, Walter Wukovits, Bettina Mihalyi-Schneider and Michael Harasek, TU Wien, Austria*
In studies comparing the environmental impacts of renewable fuel production using biomass feedstock with fossil-based alternatives, the analysis often focuses on net greenhouse gas (GHG) emissions, excluding biogenic carbon dioxide emissions. However, this neglects the high carbon intensity of biomass-based processes, a factor often overlooked when calculating net GWP emissions, as suggested by the IPPCC.
To fill this gap, this study considers CO2 biogenic emissions and relevant impact categories affected by the use of biomass such as acidification potential, eutrophication potential, particulate matter, land use and water use, following the environmental footprint 3.1 method.
The aim of this study is to provide a comprehensive overview, identify the key environmental hotspots of different scenarios, and propose areas for improvement.
For this a cradle to gate life cycle assessment is (will be) performed using experimental and simulation data from previous studies.
The study highlights the importance of renewable electricity sources and CO2 capture in tackling GHG emissions. It also shows that the choice of feedstock can significantly impact other environmental categories, such as land use, eutrophication, and acidification, emphasizing the need for sustainable farming practices and the development of technologies aiming to use residues and waste as feedstock.
Most importantly, by calculating the biogenic CO2 emissions the study shows that these are not negligible. Therefore depending on how biogenic CO2 emissions are accounted for, these technologies could emit more CO2 than current systems, reinforcing the need to focus on reducing the carbon dioxide stock in the atmosphere.
The results of this analysis will contribute to decision making by highlighting the most promising directions for the development and improvement of these technologies.

5.06.P-We420 Exploring Multiple Approaches to Biogenic Carbon Assessment: A Comparative Life Cycle Assessment of Wooden and Resin Flooring in the Nautical Sector
Federico Bedogni*, Eleonora Rossi, Francesco Arfelli, Daniele Cespi and Fabrizio Passarini, University of Bologna, Italy*
Despite significant strides toward sustainability, in 2018, the maritime sector was responsible for approximately 3% of global greenhouse gas (GHG) emissions and around 13% and 15% of SO2 and NOx global emissions, respectively, mainly due to fuel consumption. Still, the focus on the environmental impacts of ship materials has been increasing recently. This study aims to conduct a comparative life cycle assessment (LCA) of two boat flooring alternatives, i.e., one wooden-based (teak) and one fossil-based (resin), considering their entire life cycles, thanks to primary data provided by the manufacturer for the wooden-based material. The main focus, beyond comparing the two alternatives, was to assess biogenic carbon and its uptake using various approaches. This is particularly relevant because different methodologies can lead to significantly varying results, demonstrating several shortcomings and blindness, heavily influenced by the end-of-life scenario (landfilling or incineration). Two standard procedures for long-term emissions (ISO 14064 and IPCC) were considered, alongside the 0/0 and -1/+1

approaches, shaping different use phase scenarios for treated and non-treated wood panelling. The selected functional unit (FU) is 1 m2 of flooring material, and a cradle-to-grave approach was adopted. The LCA modelling was done using SimaPro software (v.9.5), with the ecoinvent database (v.3.10) applying IPCC 2021-GWP100 as the analysis method for Climate Change (CC) contribution and ReCiPe 2016 for all the other midpoint categories. The results show that wooden products have a lower impact than resin in every scenario, even considering long-term emissions, regarding CC, particulate matter formation, human carcinogenic and non-carcinogenic toxicity (not land use) which represent 98% of the total contribution on the ReCiPe 2016 single score (perspective H). The geographical and temporal distribution of these regional impact categories contribution is also commented on. A mitigation of the overall impacts thanks to energy and heat recovery during waste to energy, especially concerning the woody fraction, is observed. A general increase in the impacts can be observed in the treated wood panelling with respect to the non-treated one. The emission profile over time was evaluated to improve the monitoring of CC contributions and to better understand possible actions for their mitigation, process not obtainable through traditional calculation tools.

5.07 Life Cycle Assessment Relevant Resource Indicators for Providing Guidance Towards a Transition to a Resilient Carbon Neutral and Circular Economy

5.07.T-01 Integrating physical material quality of recycled materials as part of the life cycle inventory in life cycle assessment

***Simon Alexander Saxegaard**, Pieter Callewaert and Valentina Helen Pauna, Norwegian Institute for Sustainability Research (NORSUS), Norway*

The EU is implementing circular economic policies to reduce the environmental burdens of its material economy. A key pillar of circular economy is recycling which is proposed as one of several material strategies in the Packaging and Packaging Waste Regulation. A research gap within recycling in LCA is understanding how to address physical material quality when developing life cycle inventories of recyclable and/or recycled materials. Recent research demonstrates that additives, contaminants, inks, and other substances have a negative influence on the material quality, which again affects the market applicability of recycled material and how many times a material can be recycled. Both of these aspects affect the usable recycled output at a product level, and the net recycled content across a recycling cascade and subsequently at the market level.

This research aims to integrate emerging research on the physical effects of additives, contaminants, inks, and other relevant substances on recycling into a life cycle inventory modelling approach for addressing its environmental influence on recyclable or recycled materials. To do so, a multi-scope and multi-method approach is applied to integrate the consequences of material quality on the material flow between product systems within a recycling cascade and its extended effects on and from the market material economy. Current literature states that it is not necessarily environmentally beneficial to only increase the recycling rate of recyclables. Rather, there is a need for a market that fosters the inclusion of recycled and recyclable materials. This research will find how material quality affects the recyclability of plastic materials as well as identify which, and how much, recyclable plastic can be used. Further, the results will demonstrate the physical and environmental effects of the material flow of recyclables through a material economy. These results provide a method for integrating material quality of recyclables as part of the LCI when addressing recycling and recycling systems.

5.07.T-02 A Change of Paradigm on Mineral Resources Flows in LCA: Necessary, and Feasible

***Antoine Beylot**[1] and Jo Dewulf[2], (1)BRGM, France, (2)Ghent University, Belgium*

The assessment of impacts associated with mineral resource use has long been debated among LCA method developers and practitioners. Several methods (including the EDP, ADR/LPST, ARP, JRC-LCI, CTI-LCIA and EVDP methods) have been developed in the recent years to go beyond the assessment of contributions to resources depletion over a product life cycle in LCA, and to rather assess contributions to reduction of resource accessibility and resource dissipation. This study builds on, and extends, a review on the fundamentals of these recently developed methods, including key underlying choices and assumptions, and operationalization. It moreover analyses the terminology associated with material flows in LCI modelling, and discusses the implementation of material balancing in process engineering and Life Cycle Thinking.

This study highlights the two pivotal aspects that make a change of paradigm on mineral resources in LCA necessary. Firstly, some recently developed methods pledge for new LCIs to be developed (JRC-LCI method), or require the development of new LCIs (EVDP, CTI-LCIA) for any potential wide implementation. These new methods call for a deep change of paradigm on modelling mineral resources in LCIs, no longer considering only primary mineral resources extracted from ground, but also mineral

resources flows within the technosphere, or from the technosphere to the ecosphere. Secondly, rethinking mineral resources flows in LCIs is necessary to support the development of material-balanced LCIs. The latter contribute to more consistent and complete accounting of intermediate exchanges, emissions and resources flows at the unit process level.
Moreover this study develops a stepwise approach to make this change of paradigm feasible in LCA practice. This approach integrates material accounting and balancing principles in LCI results, enabling to derive balanced LCI datasets and databases. It builds on a new nomenclature of mineral resource flows, not only extracted from ground but also exchanged within technosphere, and from technosphere to ecosphere. This framework is showcased with a step by step implementation to the case of the production of a battery raw material, using ecoinvent datasets. The influence on toxicity- and resources-related impact categories is discussed, particularly highlighting the benefits gained from this framework towards sounder support to decision-making with LCA.

5.07.T-03 Scenario-Specific Characterization Factors of Dissipative Flows of 53 Abiotic Resources: Introduction to the ACP and RESEDA Methods
Titouan Greffe[1]*, Manuele Margni*[2] *and Cecile Sophie Marie Bulle*[1]*, (1) UQAM, Canada, (2) University of Applied Sciences (HES-SO), Switzerland*
Abiotic resources such as fossils, metals or non-metallic minerals are essential to industrialized societies. Through their use in multiple products, they provide services such as mobility, conditioned living space or worldwide instantaneous communication. The extraction and the transformation of these abiotic resources made available in the technosphere into different products enable human society to access to these services. Losses of these resources along their life cycle (e.g. primary production, use phase or recycling), here called dissipative flows, can potentially reduce the provision of those services. To meet the global demand of services, additional extraction flows may be required to compensate the dissipative flows. This additional extraction requires an supplementary energy consumption. We developped the Additional energy Cost Potential (ACP), a life cycle impact assessment method which quantifies an additional energy cost of a marginal dissipative flow (in MJ per kg of dissipative flow), integrated over time (from now to 2100) and space (global level). Characterization factors of dissipative flows range from 1.75E5 MJ/kg dissipative flow of Platinum to 1.3E-1 MJ/kg dissipative flow of iron. Moreover, there is a maximum yearly amount of metals that can be extracted given the capacity of worldwide mines to extract. If the global demand is superior to the global mining capacity, users of a resource may face a deficit as the products providing a service cannot be produced. We introduce a complementary life cycle impact assessment method, named REsource SErvices Deficit Assessment (RESEDA) method which quantifies the deficit quantity (in unit of mass) resulting from a marginal dissipative flow. This corresponds to the situation where the dissipative flow cannot be compensated by an extraction flow, as demand is above mining capacity. We determined characterization factors of dissipative flows of 50 metals and three fossil fuels (crude oil, natural gas and coal) for each scenario with the RESEDA method. Characterization factors of dissipative flows range from 0 kg deficit/kg dissipative flow of iron to 0.93 kg deficit/kg dissipative flow of cobalt.

5.07.T-04 Spatially and Temporally Differentiated Characterization Factors for Supply Risk of Abiotic Resources in Life Cycle Assessment
Anish Koyamparambath[1]*, Philippe Loubet*[1]*, Steven B. Young*[2] *and Guido Sonnemann*[1]*, (1)Universite de Bordeaux, France, (2)University of Waterloo, Canada*
Life cycle assessment (LCA) is a commonly used method for evaluating environmental impacts throughout a product s life cycle, generally focusing on "inside-out" impacts such as resource consumption and global warming. However, the "outside-in" perspective, which considers the availability and accessibility of resources to industry, is gaining more attention. This approach incorporates raw material criticality assessments into LCA, offering a broader view of supply risks. The GeoPolRisk method evaluates geopolitical supply risks by examining factors like production concentration, import shares, political stability, and commodity prices. This article introduces a characterization model for GeoPolRisk, calculating the Geopolitical Supply Risk Potential (GSP) for 46 raw materials across various countries and years. The results reveal significant variations in GSP values, particularly for precious metals like platinum group metals, which are produced in politically unstable regions. The case study on energy

supply security illustrates how the GeoPolRisk method provides valuable insights into the supply risks of critical raw materials, complementing traditional environmental indicators like global warming in LCA.

5.07.T-05 Holistic Sustainability Assessment of Packaging – the Viennese Model of Sustainability Assessment

Manfred Tacker[1]*, Charlotte Neumair*[1]*, Silvia Apprich*[2] *and Michelle Klein*[2]*, (1)Circular Analytics TK GmbH, Austria, (2)Universsity of Applied Life Sciences FH Campus Vienna, Austria*

The regulatory landscape for packaging in Europe is changing rapidly. The recently adopted Packaging and Packaging Waste Regulation (PPWR) and the Corporate Sustainability and Reporting Directive (CSRD) set new requirements on packaging sustainability Standardisation and industry wide cooperation along the supply chain is necessary to fulfill these requirements.

For sustainability assessment of packaging a holistic model is required to include all relevant sustainablity indicators and prevent burden shifting. The Viennese Model of Sustainablity Assessment was developed together with companies along the supply chain to select KPIs and methods for a holistic sutainability assessment including circularity and product protection that fulfills the upcoming regulatory requirements. A benchmarking study of dairy packaging currently on the European market shows that a significant number of packaging formats are not fit for 2030 being either not recyclable or showing high environmental burdens. Holistic sustainability assessment combining circularity, environmental and product protection Key Performance Indicatiors is essential to identify opportunities for optimisation, prevent burden shifting and monitoring environmental performance of packaging. Limited emptiability of packaging, an often overlooked indicator can have very large impact on environmental performance and contributes significantly to food waste and should be prevented by design changes.

5.07.P Life Cycle Assessment Relevant Resource Indicators for Providing Guidance Towards a Transition to a Resilient Carbon Neutral and Circular Economy

5.07.P-Tu430 Understanding the Production of Natural and Synthetic Battery-grade Graphite: European Union Perspective on Supply Risk and Environmental Impact Implications

Aina Mas Fons[1]*, Anish Koyamparambath*[2]*, Jair Santillan Saldivar*[1]*, Frederic Lai*[1]*, Mathieu Leguerinel*[1]*, Daniel Monfort Climent*[1]*, Philippe Loubet*[2] *and Guido Sonnemann*[2]*, (1)BRGM, France, (2)University of Bordeaux, France*

Lithium-ion batteries are vital for e-mobility, with graphite as a key anode material. As e-mobility grows, demand for battery-grade natural graphite (NG), classified as a critical raw material for the European Union (EU) and synthetic graphite (SG) will rise. Though NG and SG have similar structures, they differ in origin, production processes, properties, and cost. Both involve energy-intensive production with potential environmental impacts, raising concerns in the EU, which aims to cut emissions and strengthen supply chain resilience. This study evaluates environmental impacts, with a focus on climate change (CC), and supply risks for battery-grade NG and SG to align with the EU s goals for resilient and sustainable battery production.

Environmental impacts are assessed using Life Cycle Assessment with 1 kg of battery-grade graphite as the functional unit. Reliable LCI datasets are remodelled using ecoinvent 3.10 for background data. Two production routes, NG and SG, are analyzed. Supply risk is assessed using the GeoPolRisk method from an EU perspective, focusing on flake graphite and needel coke, as well as covering raw materials in the background system.

Preliminary results show that producing 1 kg of NG results in a potential CC impact of 5.4 kg CO2eq., while SG production results in 10.3 kg CO2eq. GeoPolRisk scores for the EU are 0.3 for flake graphite and 0.05 for crude oil (a preliminary proxy for needel coke). While NG s lower CC results supports EU sustainability targets, its reliance on Chinese production raises supply risks unless new deposits are developed or stable trade agreements are secured. SG presents lower supply risk but higher CC results due to energy-intensive processing.

Neither NG nor SG is expected to dominate the anode market, both will play roles in sustainable battery development. This study integrates supply risk assessment into LCA and provides GeoPolRisk scores for compounds beyond raw materials, offering insights into trade-offs between environmental impacts and supply risks to support the EU s sustainable mobility goals. It also provides a foundation for scenario development, considering variables like recycling rates or new technologies.

5.07.P-Tu431 Integrative Review of Circular Strategies: Developing a Value Assessment Framework

*Jannie Coenen, **Lowik Pieters** and Johannes Lijzen, RIVM Dutch National Institute for Public Health and the Environment, Netherlands*

Over the past decade, nations including Brazil, China, Canada, EU countries and the US have worked on policies for a circular economy (CE). These mention high-quality recycling as essential strategy for a CE, but do not specify which (quantitative) metrics define quality of secondary materials. The lack of a definition and indicators limits comparing strategies, and measuring and evaluating the progress of the transition towards a CE.
With an integrative literature review in progress, we aim to come to a solid framework that incorporates a range of metrics for assessing quality in terms of values associated with processing and the application of secondary materials across multiple use cycles. The scope of the study is abiotic and biotic waste management. We focus on the post-use R-strategies reuse, repair, repurpose, refurbish, remanufacture, recycle, and regenerate, all aimed at bringing materials into a new usage cycle. Consequently, energy recovery and strategies to reduce primary inputs are not included in this analysis.
A search was carried out in Scopus and Web of Science with search string: (TITLE-ABS-KEY (circular* OR closed-loop* OR revers* supply chain*) AND TITLE-ABS-KEY (value creat* OR value retent* OR value preserv* OR value maint* OR quality of recycl*)). This search yielded a total of 5,380 results. We used three a priori criteria for inclusion: 1) relation to the circularity, closed-loop or reverse supply chain research field; 2) inclusion of post-use R-strategies; 3) inclusion of quantification of value and if yes: minimum two different value aspects (environmental, social, economic, technical). The large number of records was initially analysed using machine learning-assisted software, which evaluated titles and abstracts against the established selection criteria. Subsequently, 416 approved records underwent manual verification by a different researcher. To date, we have selected and analysed metrics from 25 papers, and we are currently in the process of reporting and comparing equations and parameters.
Initial findings yield 34 metrics. The majority pertain to environmental quality, while several quantify technical quality and efficiency. Some metrics encompass other socio-economic metrics, such as job creation and health impacts. Commonly used methods are life cycle assessment, multi-criteria decision analysis and mixed-integer linear programming. We observe that metrics often overlook the dynamic interactions among parameters.

Disclaimer/Disclosure: This research is funded by the Dutch Ministry of Infrastructure and Water Management.

5.07.P-Tu432 An Integrated Approach to Quantify the Life Cycle Impacts and Circularity of the Digital Infrastructure

Thomas Hennequin, *Aaradhya Bansal, Martijn Kamps, Ivan Vera Concha and Felipe Blanco Rocha, TNO, Netherlands*

Digital services, such as video streaming, artificial intelligence, or office software use, tend to appear as immaterial, the so-called cloud . Actions are performed with the touch of a screen, or the click of a mouse, while the supply chains that enable these services are invisible to end users. The consumption of digital services is increasing globally. Corporate and governmental strategies increasingly include digitalization as a sustainability measure. Yet, digital services are not immaterial or invisible, they instead rely on material- and energy-intensive infrastructure to transmit, process, and store data. We lack a clear understanding of the environmental consequences of this growing digital infrastructure.
Scientific research on the environmental sustainability of digital services and infrastructure faces several main challenges: (1) data that is scarce and lacks transparency, (2) carbon tunnel vision with a focus on use phase energy consumption, omitting other impacts, and (3) truncated system boundaries, often overlooking end-of-life of e-waste. Only by addressing these challenges can we provide transparent advice needed to guide user behavior, corporate decision-making, and policy design.
In our work, we aim to develop an integrated assessment model in an effort to overcome these challenges. We will evaluate the life cycle greenhouse emissions and circularity of key groups of information and communication technology products and their connection to the rest of the global economy. Our approach allows for the modelling of interventions, such as EU policy measures, novel circular technologies, or sustainable data centers, and provides insights into the mitigation potential of such interventions. Our hybrid methodology combines bottom-up and top-down approaches and is rooted in prospective life cycle assessment and dynamic material flow analysis.
With our results, we will provide a robust and transparent overview of the digital infrastructure and its impact on climate change and material scarcity. We aim to show the evolution of impacts over time and gain insights into the link between the digital infrastructure and the rest of the economy. We will also reflect on the usefulness and limitations of the different methodological tools that were utilized. Finally, we aim to provide recommendations on the most effective strategies to sustainably use digital services.

5.07.P-Tu433 How to Assess Impacts on Biodiversity of Metal Sources? Providing Indicators for Decision-Making

Anne Asselin[1]*, Joséphine Gatin*[1]*, Chunqi Hui*[3] *and Ambre Brizon*[3]*, (1)Sayari, France, (3)L'Oreal, France*

Metal mining and refining are sources of impact on biodiversity, through land (and potentially sea) use change, pollution, and climate change. Major impacts occur at the two first steps of the value chain, namely ore extraction and smelting. Businesses are looking for simple yet robust criteria to define and improve their sourcing. Metals production can indeed impact biodiversity within diverse ecosystems within the three biotas: terrestrial, freshwater, and marine.

Building on existing literature, and based on a life cycle approach, we developed a semi-quantitative assessment method for metal sources, prioritizing the most important cause effect chains. As for the method, we i) first identified three metals of interest with diverse technical extraction practices ii) did a literature review, gathering information on main mining spots and practices, as well as on pressures on biodiversity caused by mining iii) identified the main drivers (land and water use, metal pollution) and built a semi-quantitative method based on cause-effect chain, with resulting rating on a scale from 1 (very good) to 7 (very bad) iv) completed our work with a quality assessment of the rating v) tested it on 15+ case studies.

Our method assesses impacts on biodiversity from water and land use, heavy metal pollution, and GHG emissions. It covers terrestrial, freshwater, and marine biota, and combines the magnitude of each pressure with the receiving ecosystem vulnerability, using the Global Extinction Probability combined with assessment of governments integrity and environmental policies. We have been testing it on 15 mining and refining facilities and are currently further expanding the testing especially for copper and cobalt in China and DRC. Those case studies present various challenges e.g., allocation between coproducts (in the case of copper and cobalt in DRC); scarce and incomplete data on metal pollution; local and generic data; aggregation of marine, freshwater and terrestrial impacts, consistency of available data from various sources (governments, companies reporting, NGOs)

Project is still ongoing; results of testing will be presented at the conference. We will also shed light on practical data collection and quality and discuss how to provide actionable yet robust indicators for business decision-making.

5.07.P-Tu434 TOC/TN Measurement for the Control and Evaluation of Methane Fermentation of Food Waste

Yoshio Ikezawa*, Shimadzu Corporation, Japan*

Methane fermentation is a biological process in which microorganisms decompose organic materials such as food waste in the absence of oxygen. Methane gas generated through the process is a renewable energy source and fermentation residue can be used as fertilizer. In Japan, a research laboratory have been developing a recycling system which food processing companies adopt methane fermentation plants. In the investigation to make this process improvement, Total Organic Carbon analyzer withTotal Nitrogen detector has been applied becaue the ratio of TC and TN is pretty relating to the efficiency of the process of mehance gas generation. This presentation will show how TOC and TN measurement is working for the optimization research process development.

5.07.P-Tu435 Facilitate Decision Making in LCA Introducing the Measure of Resource Efficiency

Antoine Beylot[1]*, Guido Sonnemann*[2] *and* ***Louis Freboeuf***[2]*, (1)Bureau de recherches geologiques et mini res (BRGM), France, (2)Universite de Bordeaux, France*

The presentation will first describe the meaning of measuring Resource Efficiency in Life Cycle Assessment (LCA).

Reminding the different resources that are, or that could be inventoried in LCA, and the different way of characterizing them in regard to the safeguard subject identified by the GLAM 2024. The consequences are conceptually described as The consequences can be the requirements of additional efforts to compensate lost values or the lost values per se as externalities of natural resource use.

Then the notion of circularity is introduced with its importance for human growth [1], its interest for economies, for instance in the Circular Economy Action Plan (CEAP) of the European Commission among other regional initiatives [2,3]. The interest of accounting for the reversibility of a system flows are presented as an interest for LCA to resolve multifunctionality in process-oriented studies [4], and physical balance [5] issues in traditional attributional LCA studies. Circularity initiatives for circularity metrics implementation are presented [6].

Then, a metal recycling system, at the heart of the Circular Economy (CE) state, will be assess using different implemented resources CE metrics. The different metrics will be grouped in function of their decision-making insights. The causes of their differences will be assessed. Based on these insights, a proposing of considerations for the incorporation of Resource Efficiency measuring in the LCA

framework will be presented.
The case study s data exploited come from [7].
This presentation subscribes in the dynamic of normalizing circularity assessment technics in the framework of life cycle thinking. Indeed Life Cycle Assessment (LCA) is considered as a promising tool according to the last version of the (International Organisation for Standardization, 2024) [8].

5.07.P-Tu436 Developing a Comprehensive Framework for Optimal Circular Cascading Use of Wood: Sustainable Criteria and Application Selection

Nadia Ilaria Malinverno[1]*, Arthur Jakobs*[2]*, Kealie Vogel*[1]*, Bernd Nowack*[1]*, Esther Thurig*[3]*, Gustav Nystrom*[1] *and Claudia Som*[1]*, (1)Swiss Federal Laboratories for Materials Science and Technology (Empa), Switzerland, (2)Paul Scherrer Institut (PSI), Switzerland, (3)Swiss Federal Institute for Forest Snow and Landscape Research (WSL), Switzerland*

Wood, a versatile and renewable material, plays a significant role in various industries and is a key resource for the bioeconomy. Forests and sustainable wood use are expected to be essential in reaching net-zero goals by sequestering CO2 in biomass, storing CO2 in materials, and substituting fossil resources. However, a systemic understanding of wood s life cycle complexity is required to defossilize society and promote circular bio-based developments. By recognizing wood as a complex material, with changing properties throughout its lifespan, we developed a material flow analysis (MFA) method covering the entire Swiss wood value chain -from harvest to products, societal use, collection, recycling, energy generation, and trade. We now expand on this work by integrating life cycle assessments (LCA) and identifying pathways to maximize the duration and environmental efficiency of biomass use in the technosphere and investigating the cascading use of wood, where wood is (re)used as long as possible before energy recovery. We identified underutilized wood streams - such as damaged wood, residual wood, wood fuel, and waste wood with initial potential for cascading use, as they meet the required criteria of availability, being untreated, and having potential for reuse or recycling. We will now develop "material-first" scenarios to maximize the use of these flows as materials. This includes considering future changes in wood availability from forests and the introduction of new emerging applications and reused or recycled materials. To establish material cascades we further characterize the initially identified flows (e.g. by size/form, carbon content, contamination) and elaborate corresponding quality criteria for the wood flows to determine pathways of wood material (re)use. Finally, we will identify suitable applications for the "material-first" scenario and align wood flow quality criteria with the requirements of each application. With this, we can combine LCA and MFA and create decision support for optimal cascading use, ensuring the most efficient and sustainable use of wood resources as carbon sinks and storage in the technosphere and a mature biomass strategy of whether a flow could be used to introduce a new material application, a recycling or reuse cycle, or for energy production. Our work advances scientific understanding and offers real-world solutions for sustainable wood use and carbon mitigation.

Disclaimer/Disclosure: Our work received funding from the ETH Board in the framework of the Joint Initiative SCENE.

5.07.P-Tu437 Holistic Environmental Assessment of Packaging and Potential Material Substitution Impacts

Manfred Tacker[1]*, Tasja Hafner-Kuhn*[2]*, Andrin Gstohl*[2] *and Marius Rauch*[2]*, (1)Circular Analytics TK GmbH / University of Applied Life Sciences, Austria, (2)Circular Analytics TK GmbH, Austria*

To properly evaluate the potential life cycle environmental impacts of packaging materials, it is essential to consider a broad range of environmental factors. A thorough, science-driven assessment should aim to account for each stage of a packaging life cycle, from material production to end-of-life disposal, ensuring a holistic and well-rounded analysis of its potential overall environmental impact.
In a comprehensive Life Cycle Assessment (LCA) study according to ISO 14040 and 14044 the potential life cycle environmental impacts of 41 distinct packaging formats sampled from European supermarkets were assessed to compare polyethylene-based packaging with alternative non-plastic materials using PEF (Product Environmental Footprint) methodology for the transport and End of Life (EoL) analysis. The use phase (e.g., product loss, breakage rates) was excluded from the assessment. The following polyethylene product categories were covered:

- Collation shrink packaging (2 packaged products and 5 packaging formats)
- Heavy-duty sacks (2 packaged products and 4 packaging formats)
- Flexible food packaging (8 packaged products and 20 packaging formats)
- Pallet wrap (1 packaged product and 3 packaging formats)
- Rigid non-food packaging (4 packaged products and 9 packaging formats)

It can be shown that in a number of comparisons the substitution of PE-based packaging could lead to higher GWP-emissions. For the other impact categories considered, the results showed generally lower potential impacts for PE-based packaging (acidification, eutrophication freshwater, water use, land use), and for fossil resource use no clear trend was discerned. The study showed that banning or restricting the use of plastics such as polyethylene for food packaging could lead to higher greenhouse gas emissions for many applications. Thus, selection of the packaging formats to enable the lowest overall environmental impact is a complex process that requires comprehensive analysis.

5.08 Life Cycle Impact Assessment Modeling Including Normalization & Weighting

5.08.T-01 Getting Water Impacts Right - Methodological Developments from Inventory Modelling to Regionalized Impact Assessment in the ecoinvent Database

Thomas Sonderegger *and Guillaume Bourgault, ecoinvent, Switzerland*

The use of regionalized impact assessment methods in software and background databases is still limited. This work shows how improving water modelling and balancing, increasing regional coverage, and using geospatial data in application of regionalized LCIA methods play together for improved and regionalized water impact assessment in the ecoinvent database.
Based on discussions with ecoinvent-internal and external experts, we developed a new water balancing model for biomass growth including new flows and properties. Improved water balancing improves the reliability of amounts of water flows in inventories, which are assessed later.
Regional differences start with inventories where different ways of production can result in, for example, different water amounts to be characterized in impact assessment. Therefore, ecoinvent strives to cover more regions with regionally specific inventories. For the case of water, it is important to align global coverage where water is passed from one process to another. For example, each region with irrigated crop production will get an irrigation process specific for that region.
Currently, some software tools use regionalized elementary flows to implement regionalized methods. Brightway2 does so using geospatial data. However, there was no extensive and consistent application of geospatial data to the ecoinvent database yet. Maps for crop production, for example, allow connecting inventories to native spatial scales of methods such as AWARE for water impacts: we can compute how much crop is produced in which watershed within a region, which allows calculating regionally weighted characterization factors. First results from applying these characterization factors show that the suggested approach can be implemented on a background database. Comparing regionalized results to those using a global characterization factor show changes to be as expected, which confirms that the approach works and improves water impact assessment.
ecoinvent s efforts in improving and regionalizing inventories as well as the approach of using geospatial data improve water impact results. This will offer regionalized impact assessment scores to ecoinvent users and possibilities for software and tool developers to use background LCA databases for regionalization in new ways. All this helps strengthening regionalization efforts in the LCA community.

5.08.T-02 Midpoint Characterization Model for Water Consumption Impacts on Aquatic Ecosystem: RESCUE Model

Masaharu Motoshita[1]*, Kamrul Islam*[1]*, Markus Berger*[2]*, Anne-Marie Boulay*[3]*, Stephan Pfister*[4]*, Georg Seitfudem*[3]*, Francesca Verones*[5] *and Matthias Finkbeiner*[6]*, (1)AIST, Japan, (2)University of Twente, Netherlands, (3)CIRAIG, Canada, (4)ETH Zurich, Switzerland, (5)NTNU, Norway, (6)Technische Universitaet Berlin, Germany*

The impacts of water consumption through life cycle of products/services/organizations have been the subject of considerable debates. The AWARE model has been widely used for the assessment of the impacts of water consumption as a generic midpoint indicator, while demand for ecosystem-specific characterization models for water consumption has been increasing with the growth of request and interest in sustainable management of ecosystems along with the international initiatives, e.g. IPBES, Taskforce on Nature-related Financial Disclosures, and Nature Positive Initiative. In response to this demand, we have developed a new midpoint characterization model for assessing the impacts of water consumption on aquatic ecosystems: RESCUE model. The developed ecosystem specific model has some similarity with AWARE model in the modeling concept, while it specifically captures the potential impacts on aquatic ecosystems. First, environmental water requirement for aquatic ecosystem is defined based on the flow regimes in a watershed, and then, overconsumption of water by human activities is determined to assess the extent of deprivation of water for aquatic ecosystem as a potential impact on ecosystems. We have developed characterization factors for around 11,000 watersheds covering the whole globe which can be also aggregated into country scale. As a result, 67% of the global watersheds where we consume water already face the deprivation of water for aquatic ecosystem. The extent of deprivation reaches at 60% of water for aquatic ecosystem requirement. In this presentation, we present the details of the model and results, and highlight the similarity and differences between RESCUE and AWARE model.

5.08.T-03 Accounting for Specific Impacts of Fisheries in the Environmental Footprint Method – Combining Fishery Science and LCA

Anne Asselin[1]*, Brown Elliot*[2]*, Clara Ulrich*[3]*, Ian Vazquez-Rowe*[4] *and Nicola Ferrara*[5]*, (1)Sayari, France, (2)DTU, Denmark, (3)IFREMER, Chemical Contamination of Marine Ecosystems (CCEM), France, (4)PUCP, Peru, (5)EC-JRC, Italy*

The Product Environmental Footprint (PEF) has been designed by the European Commission (EC) to assess and disclose environmental footprints of all consumer goods in Europe. However, when it comes to fishery products, indicators related to i) (the living) resource exploitation and ii) seabed impacts from fishing gears such as bottom trawls are lacking, despite being major drivers of environmental impacts from fishing.

The EC has asked four experts (two LCA experts and two fishery scientists) to provide recommendations on how to address those impacts in the Environmental Footprint (EF) method. The experts first completed a review of methods to assess environmental impacts of fishing on i) resources and ii) seabed impact. Each expert was assigned one of four domains, defined as a combination of i) an impact pathway (resource or seabed) and ii) a science realm (LCA or fishery science); each completed the review, and recommended a single, most up to date method in his/her assigned domain, resulting overall in 4 recommended methods. The experts then discussed the possibility of incorporating each of the 4 recommended methods into EF, adding two indicators to the current 16 indicators. They discussed if and how normalization was feasible, and they applied the methods to three fishing case studies at landing (Hake from the Bay of Biscay, fished with i) bottom trawl (case study 1) ii) midwater trawl (case study 2) and iii) Argentinian Red Shrimp fished with a pair of beam trawls (case study 3). Based on the results, they proposed a roadmap for accounting for those impact pathways in EF.

The two fishery-science-based methods have been developed by the Scientific, Technical and Economic Committee on Fisheries (STECF) of the EC; they are natively qualitative and non-additive. Proposals were made to relate qualitative and quantitative scores, and normalization factors were computed. As the CFs for the seabed-impact recommended LCA method were only available at European level, it was not possible to compute normalization factors.

Regarding impact on resources, results of case studies displayed a variability of several orders of magnitude between i) case studies 1 and 2 and ii) case study 3 for the LCA method, and a variability lower than one order of magnitude for the STECF method. Regarding seabed impact, results from the LCA method could not be computed for case study 3; the STECF method displayed a variability of a factor lower than an order of magnitude.

Disclaimer/Disclosure: The views expressed in the article are personal and do not reflect an official position of the European Commission.

5.08.T-04 Cellulosic Versus Synthetic Fibers: How Do They Compare in a Life Cycle Assessment When Fibers Emissions are Included?

Nadim Saadi *and Anne-Marie Boulay, CIRAIG, Department of Chemical Engineering, Polytechnique Montreal, Canada*

Textile clothing is a significant contributor to microfiber pollution in marine ecosystems. A significant portion of microfibers emitted are cellulosic-based, either natural (e.g. cotton and linen) or regenerated cellulose (e.g. viscose and lyocell). When emitted, these particles are readily ingested by marine organisms, posing harmful effects even at environmentally relevant concentrations.

In Life Cycle Impacts Assessment (LCIA), characterization factors (CFs) have been established for synthetic microfibers. However, no such CFs exist for cellulosic microfibers (CMFs) due to the lack of exposure and effect factor (EEF) specific to these fibers. Current LCIA methods therefore overlook potential environmental impacts from CMFs. Given that natural and regenerated cellulosic textiles release more microfibers when washed and are found in greater abundance in the environment than synthetic microfibers, CFs specific to these fibers are an important gap that this work aims at addressing.

The fate of CMFs in the marine environment combines the fate in the water column and sediments, differentiating between different CMFs materials and sizes. Further, an EEF for CMFs is developed. The EEF is calculated from a hazardous concentration of 20% (HC20), derived from a species sensitivity distribution (SSD) of effect concentrations of 10% (EC10). The EEF was extrapolated to sediments and the fate was combined with EEFs to obtain midpoint and endpoint CFs that include impacts in water and sediments. The CFs were then tested in a textile LCA case study, comparing the cradle-to-grave ecosystem quality impacts of a cotton t-shirt and a polyester (PES) t-shirt.

The EEF obtained is 2950 PAF.m3/kg, which is not significantly different from that of MPs. Marine midpoint and endpoint CFs for 6 cellulosic materials (cotton, linen, viscose, rayon, lyocell and modal) of 5 different sizes (1 to 5000?m) and their uncertainty were computed. For the same size, the CFs of CMFs are on average one to two orders of magnitude smaller than the CFs of synthetic microfibers, largely due to their smaller residence time (due to faster degradation) in the marine environment. In the textile case study, the impacts of PES emissions were found to be a significant contributor to EQ damage, but not in the cotton t-shirt case. Multiple sensitivity analyses on the use location, end-of-life scenario and release rates are conducted. CFs for CMFs are readily available for environmental decision-making.

Disclaimer/Disclosure: The authors thank the financial support of the Canada Research Chairs Program.

5.08.T-05 Life Cycle Impact Assessment for Positive and Negative Impacts of Offshore Wind Farms on Benthic Marine Biodiversity

Liv Stranddorf[1]*, Francesca Verones*[2] *and Stig Olsen*[1]*, (1)Technical University of Denmark, Denmark, (2) Norwegian University of Science and Technology (NTNU), Norway*

The construction and decommissioning of offshore wind farms affect the marine ecosystem by changing the marine habitat. Construction can occur in different substrate types, and decommissioning can follow scenarios varying from complete removal to leaving parts of the structure in the sea, and each scenario will impact marine biodiversity differently. But how to make informed decisions when quantitative assessment methods representing the marine biodiversity impacts of marine habitat changes are lacking?

In this study, we develop Characterization Factors (CFs) for life cycle impact assessment considering the benefits and impacts of offshore wind farm construction and decommissioning on marine benthic biodiversity. The CFs are disaggregated for different taxonomic groups and alien species to allow for assessment of the species composition.

We use a dataset that includes data on benthic species richness for 17 offshore structures and natural seabed samples in the North Sea. The species identified in the dataset are divided into 8 different taxonomic groups based on their phylum, and alien species are determined by comparing the species to the IUCN list of alien species in the North Sea. For each taxonomic group and alien species, we developed polynomial models expressing the species richness on the structure as a function of structure age, seabed type, and decommissioning scenario. The richness models are used to develop CFs expressing the locally disappeared or gained fraction of species associated with each construction or decommissioning scenario, integrated over the considered timeframe (PDF.year).
The species richness on the structures generally increases during the structure lifetime, but the CFs show that construction on soft seabed generally results in a net species loss, while construction on hard seabed results in a net gain of species. All decommissioning scenarios result in a loss in the total number of species, but the CFs indicate that leaving parts of the structure will preserve 80-99% of the richness. Additionally, the CFs indicate that construction and decommissioning activities will cause considerable changes in the richness of alien species and shifts in richness between taxonomic groups. The developed CFs provide a basis for understanding and managing the ecological consequences of offshore wind projects, considering both positive and negative impacts and the changes in species composition.

5.08.P Life Cycle Impact Assessment Modeling Including Normalization & Weighting

5.08.P-We421 Influence of Different Normalization and Weighting Methods in Life Cycle Impact Assessment: Single-Score Assessments of a District Cooling Plant

Eva-Maria Wiener[1]*, Gerhard Piringer*[1]*, Rosa Weber*[1]*, Raphael Schauer*[1]*, Gilbert Ziesser*[2] *and Stefan Buchner*[2]*, (1)University of Applied Sciences Burgenland, Austria, (2)Wien Energie GmbH, Austria*

District cooling plants are becoming increasingly important as they play a key role in providing energy efficient and sustainable urban cooling solutions when climate change drives temperature increases globally. Single-score results in LCIA can enable effective communication and decision making. The aim of this study is to investigate the effects of different normalization and weighting methods, applied to the case study of the district cooling plant "Wien Schottenring," in Vienna, Austria.
The plant has a cooling capacity of 19.8 MW and operates a combination of three compression chillers and two absorption chillers. The compression chillers are powered by grid electricity, while the absorption chillers use predominantly district heat as their energy source. A time-resolved modelling approach is used to analyze electricity and district heat supplies as well as the cooling demand, taking into account time variations in energy flows and consumption. LCA results will be compared for two cooling variants:

Variant 1 (existing configuration): Cooling with both absorption and compression chillers.
Variant 2 (alternative configuration): Cooling with compression chillers only.

Various normalization and weighting methods will be applied to arrive at single-score LCIA results. These include ReCiPe, EF 3.1, the ecological scarcity method, and alternative normalization approaches from recent literature. Finally, a normalization based on national Austrian data will be applied to account for regional specificities.
The robustness of the comparison between the two variants will be evaluated with regard to the choice of normalization and weighting approaches and to the resulting single-score results. Also, the contributions of individual categories to the single score will be analyzed, both for uniformly weighted normalization methods and for weighting methods (ReCiPe and EF). Finally, we will show the effect of applying a regionalized Austrian normalization set compared to the global and EU-wide normalization sets.
The study will apply a range of normalization and weighting methods to one of the future key technologies for urban climate change adaptation. Single-score LCA results can easily be communicated to non-experts, making a careful analysis of the underlying methods critical to providing robust decision support for industry and policymakers.

Disclaimer/Disclosure: This work was supported by the Josef Ressel Centre for Linked System Assessment to Support Sustainable Energy Supplies - LiSA, Department of Energy and Environment, University of Applied Sciences Burgenland. The authors gratefully acknowledge the financial support provided by the Austrian Federal Ministry of Labour and Economy, the National Foundation for Research, Technology and Development, and the Christian Doppler Research Association.

5.08.P-We422 Simplified Environmental Scores for Greener Vehicle Procurement: Evaluation of Weighting Effects in Belgium's Ecoscore

Lea Jacqueline Annina D'amore[1], *Maeva Lavigne Philippot*[1], *Tobias Denys*[2] *and Maarten Messagie*[1], *(1)Vrije Universiteit Brussel, Belgium, (2)VITO/EnergyVille, Belgium*

Life cycle assessment (LCA) is a great tool to enhance more sustainable procurements of vehicles. However, it can be quite complex for non LCA-experts. It is why, in several countries, environmental rating tools for vehicles emerge as they are easier to understand, using a simple, comprehensible value. In Belgium, Ecoscore were developed in 2003, providing a single score for each car in the Belgium fleet and used both by consumers and policymakers. The creation of such scores typically involves normalization and weighting steps, which can introduce uncertainties. The goal of the study is, for the specific case of the Belgium score, to assess how Ecoscore can balance between simplified results communication and accuracy of the underlying data.

The Ecoscore method is currently being updated from a well-to-wheel approach to LCA method. The normalization step has been updated by changing the reference vehicle to an electric vehicle with a 27.8 kWh battery. In addition, the Environmental Footprint 3.1 (EF3.1) methodology has been adapted to include only emissions already accounted for in the original Ecoscore, as results from homologation tests are available. These emissions are classified into the corresponding impact categories. The weightings have been adapted from EF3.1.

To meet the objective, it is important to understand how the weighting of different environmental categories influences the Belgium score. The study will be carried out first, at vehicle level, where the weightings will be modelled as parameters in the LCA. A one at a time parameter modification is conducted to compare the final scores while keeping all other parameters constant. Secondly, at fleet level, the single score will be evaluated for the Belgian fleet and compared to results conducting LCA using PEF weightings and including all emissions to identify the main differences and similarities between the two methodologies.

The results will show the scores calculated at vehicle and fleet level for the different assessment method. It should provide valuable insight into whether the Belgium score is representative of the actual environmental impact of the car fleet being rated. In the context of greener procurement, it's crucial to understand how the trade-offs between simplification for non-experts and the scientific accuracy might impact the effectiveness of the score in both guiding consumers and supporting policy goals for sustainability.

5.08.P-We423 ParaBAT: A Methodology of Progressive Approaches to Improving Systems Aimed at Minimizing Waste Production Originating From Industrial Activities

***Ivanna Harasymchuk**, Vladimir Koci, Tatiana Trecakova and Eliska Purkarova, University of Chemical and Technology in Prague, Czech Republic*
Achieving the best available techniques in the operation of large industrial and agricultural facilities represents one of the most important tools for environmental protection. Reaching emission limits, or even the lower boundary of BAT (Best Available Techniques) emission limits, usually requires the introduction of new technology or modification of existing technology, which entails additional material or energy costs. The acquisition or production of these material or energy inputs typically involves technological processes that, through their operation, may release varying amounts of emissions into different environmental compartments. The aim of the ParaBAT methodology is to enable the evaluation of the actual benefit of reducing emission limits throughout the entire supply chain. Under suitable conditions, the methodology can be used to justify why the lower, stricter boundary of the BAT emission limit is not met by the evaluated technology. The ParaBAT methodology appropriately applies the LCA (Life Cycle Assessment) method and specifies its use specifically for the purposes of evaluating the achievement of BAT goals. The novelty of the methodology lies in defining a precise and clear procedure for evaluating environmental impacts using the PEF (Product Environmental Footprint) method in the Czech Republic, with a focus on technologies for the production of secondary raw materials and recyclates. The methodology describes the framework and basic procedure for assessing the environmental impacts of BAT technologies, including the accounting of input materials and energy, and the output of by-products, thus also accounting for indirect emissions from the operation of the evaluated technology.

5.08.P-We424 Characterization of Land Use Impacts on Evaporation-Precipitation Dynamics and Its Role in Earth System Functioning
***Jan Matuštík**, Charles University Environment Centre, Czech Republic*
Water plays multiple roles in the Earth system functioning and stability, and all the water sub-systems are currently affected by human activity. As one of those issues, change in evapo-transpiration caused by land use change can have a significant impact on rainfall and water availability, yet this issue is not well covered by available Life Cycle Impact Assessment methods. This study aims to model land use effects on evaporation dynamics through the lens of Earth system stability. This differs from available methods which mostly frame this issue in the context of green water flows and their effect on local soil water availability. The proposed characterization method quantifies the change in potential evapo-transpiration in comparison to a respective reference. For a study on a small scale, such as product-level, the impact is quantified in absolute values - regardless of whether the flows increase or decrease, it is a potentially adverse change from the reference stable conditions. To capture the relative importance of land use for terrestrial water availability, this change is further weighted by continental evaporation recycling ratio which measures how much of the evaporation returns to land as precipitation. Since both parameters are highly location- and season-specific, regionalization on as fine resolution as possible is advisable. However, aggregated characterization on a country and a year level seems the most practical. Next to land cover, evaporation dynamics are strongly influenced by climate and its changes. Thus, in addition to the baseline model, prospective characterization factors accounting for the effect of climate change should be developed. While the issue of evaporation-precipitation dynamics does not immediately appear as the most pressing environmental issue, the impact on water availability can be considerable in some locations dependent on moisture recycling, such as the Amazon. Hence, being able to evaluate potential impacts of products on this element of the Earth-system can allow to consider further dimensions of life-cycle environmental consequences of production systems.

5.08.P-We425 Advancing Soil Quality Integration in LCA
*Felipe Yunta-Mezquita[1], Leonidas Liakos[2], Laura Garcia Herrero[1], Valeria De Laurentiis[1], Vasco Orza[3], Giulia Listorti[1], Panos Panagos[1], Arwyn Jones[1], **Esther Sanye-Mengual**[1] and Serenella Sala[1], (1)European Commission, Joint Research Centre (JRC), Italy, (2)UNISYSTEMS, Luxembourg, (3)Piksel S.r.l., Italy*
Healthy soils are in good chemical, biological and physical condition so that they can provide ecosystem services. The Land Footprint (LAFO) model has recently been developed to estimate the EU's yearly land footprint but a geospatial component could be added to the existing model to link the land footprint information to soil characteristics. The Soil Use Calculator is a novel tool developed to estimate the environmental impacts of crop production on soil health. The calculator integrates spatial data on land use, soil type, crop requirements, soil properties, and soil erosion to assess the soil footprint of various crops. This study presents the development and application of the calculator, focusing on the impact of soil organic carbon levels on global soybean production. The calculator uses a methodological approach that considers the land area required to produce crops, soil degradation rates based on soil properties, and soil indicator thresholds. The results from LAFO model show that soybeans are the most widely imported crop

in the EU, mainly sourced from Argentina and Brazil. The global cultivated area with soybean was distributed across four levels of Soil Organic Carbon (SOC) constraints: no constraint (49%), slight constraint (37%), moderate (11%), and severe_non suitable (4%). The proposed methodology for a soil footprint calculator provides a framework for estimating the soil-related environmental impacts of crop production. The soil use calculator can be used to identify areas with high soil degradation potential and to prioritize conservation efforts, and can be integrated into EF to get a more precise environmental impact assessment by improving the baseline. Further research is needed to refine the calculator and to apply it to other crops and by using other soil characteristics, as those present in the EF Soil quality index used in impact assessment.

5.08.P-We426 Including Environmentally Relevant Effects of Microplastics in Life Cycle Impact Assessment

Sharon Desire Janssen[1]*, Joris T.K. Quik*[2]*, Anne Hids*[2]*, Koen Kuipers*[1]*, Mark Huijbregts*[1] *and Rosalie van Zelm*[1]*, (1)Radboud University Nijmegen, Netherlands, (2)Dutch National Institute for Public Health and the Environment (RIVM), Netherlands*

Plastics pollution occurs on a large scale and has become a severe environmental problem for all different ecosystems across the globe. Multiple studies have worked on incorporating micro- and macroplastics into Life Cycle Impact Assessment (LCIA). The derived effect factors (EF) in these studies are based on Species Sensitivity Distributions (SSDs) fitted to mass-based effect concentrations of often monodisperse microplastic particles. In reality, however, microplastics that occur in the environment span a wide range of shapes and sizes. As a result, the SSDs and consequently the derived EFs do not accurately represent the effects of polydisperse microplastics in the environment.

Therefore, in this study we aimed to incorporate environmentally relevant effects of microplastics on terrestrial and aquatic ecosystems in ReCiPe a multi-impact LCIA methodology. For this new EF were derived for the terrestrial and aquatic environment based on SSD that were corrected for the polydispersity of environmental microplastics and for the bioaccessible fraction. These SSDs are also used in environmental risk assessment to assess the risk of microplastics to the environment more accurately. Furthermore, fate factors for 13 polymers and for each receiving compartment were derived using an adapted version of SimpleBox4Plastics. For this, adjustments were made to be able to model the fate of plastics from a mass-based inventory flow to size-based microplastic concentrations in the receiving compartments. Subsequently, fate and effect factors were combined to derive characterization factors for microplastics in the environment.

In the presentation, we will explain the process developing the EF and FF for microplastics. Hereby, emphasizing the importance of correcting laboratory-based effect concentration for bioaccessibility and the alignment of these laboratory-based concentrations with environmentally realistic microplastic size ranges. Furthermore, we will present characterization factors for terrestrial and aquatic ecosystems. We will also use a case study to compare the developed characterization factors with earlier LCIA studies on microplastics based on a case study. Overall, the presented work increases the accuracy of LCIA for microplastics and provides tools to better evaluate the environmental impacts of plastics.

5.08.P-We427 Exploring Global Supply Chain Structures for Sustainable Consumption of Freshwater at Global and Regional Scales

Keitaro Maeno*, Masaharu Motoshita and Kamrul Islam, National Institute of Advanced Industrial Science and Technology, Japan*

The expansion of global supply chains (GSCs) of industries has led to the concentration of demands for freshwater resources in some specific regions, causing excessive pressure on local human health and ecosystems in those regions with overconsumption of freshwater. On the other hand, industrial production activities in each country involved in the GSCs bring not only such environmental interventions (i.e., negative effects) but also economic benefits (i.e., positive effects) on the local economy. However, a relationship between these opposite effects of the GSCs and GSC structures which can balance them still remain unclear in the existing literatures. In this study, we explore the sustainable GSC structures aiming at reducing water overconsumption in each country included in specific GSCs while considering the balance of the positive and negative effects at both global and regional scales. Through this process, we estimated global water overconsumption data in 2015 based on WaterGAP 2.2d model and integrated it into a multi-regional input-output (MRIO) framework. This approach allowed us to assess water overconsumption in each country involved in specific GSCs and compare it with economic value-added simultaneously generated in those country. The results focusing on the GSCs of EU s, USA s, Chinese industries revealed that India experienced the largest volume of water overconsumption, accounting for more than 25% of the total water overconsumption induced in the relevant GSCs. This result means that industries in EU, USA, China impose significant pressure on local human living and ecosystems in India through their GSCs. Conversely, we found relatively larger value-added was created by the relevant GSCs in India with respect to the volume of water overconsumption, compared to that in several African countries such as Ethiopia and Kenya. Based on these findings, we highlighted that there are large gaps between the positive and negative effects among country within the relevant GSCs, and implicated a pathway for the relevant industries to mitigate the gaps by transitioning their GSCs toward structures that balance these effects in each country.

5.08.P-We428 Improving the Accountability of Green Water Flows and Stocks in Agricultural Life Cycle Assessment

*Tamara Schmidt and **Montserrat Nunez**, IRTA, Spain*

Green water, defined as soil-stored rainwater consumed by plants through evapotranspiration (ET), is a crucial component of agricultural water use. However, it remains underrepresented in Life Cycle Assessment (LCA) frameworks, which predominantly focus on blue water (surface and groundwater). Given that agriculture accounts for ~70% of global water use and ~90% of consumption primarily through ET this omission limits the capacity to fully assess agricultural systems' environmental impacts. Current approaches to green water accounting, such as LANCA or net green water consumption, provide implicit assessments based on land use but fail to quantify environmental impacts in terms of ecosystem quality. This hinders the correct integration and impacts of green and blue water flows in LCA.
This study addresses this gap by enhancing LCA frameworks to explicitly account for green water. Building on the mechanistic framework for water use impact assessment, we employ SWAT+ (Soil and Water Assessment Tool) to model water stocks and flows in Catalonia, Spain. SWAT+ was calibrated to high-resolution datasets (20x20 m, 2013 2023) and validated against satellite-derived ET data (2019 2023). Using a hydrological model enables the unique derivation of important hydrological variables and crop-specific water demands at the same time.
Initial outputs highlight green water's significant role in water availability and flows across interconnected environmental compartments. By incorporating inter-annual and intra-annual crop rotations for mayor crops represented in augmented land-use maps, we provide more accurate results of modelled ET. At the Life Cycle Inventory (LCI) level, these results provide the basis to generate a database of average field water flow data. At the Life Cycle Impact Assessment (LCIA) level, hydrological outputs from SWAT+ enable the development of fate factors, quantifying how green water consumption affects soil moisture, aquifer recharge, and river baseflows.
Our approach emphasizes the need for accurate land-use data and calibrated models to reliably assess water consumption's environmental impacts. These insights support policies prioritizing sustainable water management, particularly in regions like the Mediterranean, where both green and blue water are critical for agriculture.

5.08.P-We429 Development of Freshwater Ecotoxicity Characterization Factors based on Nonlinear concentration-response function

***Marika Muramoto**[1], Longlong Tang[2], Wataru Naito[3], Masaharu Motoshita[3] and Norihiro Itsubo[1], (1)Waseda University, Japan, (2)National Agriculture and Food Research Organization, Japan, (3)National Institute of Advanced Industrial Science and Technology, Japan*

Of the nine planetary boundaries identified as critical thresholds for Earth's stability, six have already been exceeded. These include climate change, novel entities, and loss of biosphere integrity. This highlights the urgent need to assess chemical risks to ecosystems. Life cycle assessment (LCA) methodologies have been developed to address these risks at the global and national levels; prominent LCA models such as LC-IMPACT, IMPACT World+, and ReCiPe 2016 calculate characterization factors (CFs) for ecotoxicity. On the other hand, LC-IMPACT and IMPACT World+ rely on chronic EC50 data and USEtox models that use a 0.5/HC50 approach; HC50 (Hazard Concentration 50%) is derived from the EC50 value. More recently, CF has been calculated using 0.2/HC20, adopting an index closer to the environmental concentration, such as EC10. However, CF calculation methods remain linear; Tang et al. (2023) showed that nonlinear CFs based on toxic mode of action (TMoA) can improve the accuracy of distinguishing chemical effects. These refined coefficients can help identify priority chemicals for risk reduction but require more input data.
This study develops non-linear CFs on a global scale using the latest LCI (global chemical emissions) data. By integrating non-linear CFs with global LCI data, we aim to calculate the Normalization Value for freshwater ecotoxicity at the global level. Additionally, we compare these results with those derived using linear CFs to assess methodological differences.
The LCI data included 690 chemicals, but the number of chemicals was reduced to 505 because of the

combination with the USEtox model. Moreover, we used toxicity data from reliable data sources and only results with more than five species were used, resulting in characterization factors for 196 substances. Using the above methods, we analyzed global ecotoxicity results and attempted to identify trends in which substances are currently having the greatest impact. We compared CFs with those calculated by existing global models and compared the differences in toxicity mechanisms and HC20 toxicity data used in the Environmental Footprint, leading to future risk assessment methods with chemical substances. We will expand the range of target substances by using other toxicity test data and extrapolation methods.

5.08.P-We430 Basin-Specific Fate Factors for Freshwater Ecotoxicity of Pharmaceuticals

Tolga Ayeri[1]*, Selwyn Hoeks*[1]*, Rosalie van Zelm*[1] *and Ad Ragas*[1]*, (1)Radboud University, Netherlands*

Pharmaceuticals play a crucial role in protecting and improving human health. However, they can persist in freshwater for extended periods, ranging from months to years, since conventional wastewater treatment plants (WWTPs) may not fully remove them. Therefore, understanding their persistence in water is essential to assess the potential environmental impacts of pharmaceutical residues on aquatic ecosystems.

Life cycle assessment (LCA) is a widely used method to quantify the environmental impacts of a product or service. In the Life Cycle Impact Assessment (LCIA) step, the magnitude and importance of the potential environmental impacts of a product system are quantified. For this, characterization Factors (CFs) are used to transform emissions and resource extractions into environmental impact scores on various impact categories, such as ecotoxicity. CFs for ecotoxicity include a fate factor (FF), which describes the change in the steady-state mass of a chemical resulting from a change in emission flow. Currently, FFs for freshwater ecotoxicity are country- or continent-specific, neglecting region-specific effects. Since pharmaceuticals are sensitive to variations in local water conditions and their emissions originating from sewage systems are site-specific, there is a need to derive basin-specific FFs for freshwater ecotoxicity. Thus, this study aimed to derive basin-specific FFs for pharmaceutical emissions into freshwater across Europe at ?1 km resolution. As a proof of concept, FFs were derived for the river Ouse (UK) and Rhine basins (North West Europe) as examples. To extend this analysis, additional results for a broader range of pharmaceuticals across all European river basins will be presented during the poster or presentation.

Results showed that the FF in the river Rhine basin was approximately four times higher than the river Ouse basin, due to the larger size of the river Rhine basin. Longer river lengths within a basin result in increased retention times, allowing diclofenac to persist longer in the system. However, the generic FF for diclofenac in USEtox, a scientific consensus model to derive CFs for freshwater ecotoxicity, is 39.60 days. This value is approximately 20 times higher than the FF for the Rhine basin. These findings highlight the importance of accounting for the spatial heterogeneity of pharmaceutical emissions to freshwater within LCIA, ultimately enhancing LCA studies in healthcare.

5.08.P-We431 Clustering Methodology Developed by the EcoBeautyScore Association to Improve the Coverage of Freshwater Ecotoxicity Characterization Factors of Cosmetic Ingredients

Sophie Achigar[1]*, Alessio Aufoujal*[1]*, Laurent Gilbert*[2]*, Stephanie Johann*[1]*, Mathilde Kolenda*[1]*, Sacha Laruelle*[3]*,* ***Jacques L'Haridon***[2]*, Olena Onyshchenko*[4]*, Jennifer K. Saxe*[5]*, Pascal Seel*[6] *and Jad Zoghaib*[2]*, (1)EcoBeautyScore Association / Quantis, France, (2)EcoBeautyScore Association / L'Oreal Recherche & Innovation, France, (3)EcoBeautyScore Association / LVMH Recherche Parfums & Cosmetiques, France, (4)EcoBeautyScore Association / Henkel AG & Co. KGaA., Germany, (5)EcoBeautyScore Association / Kenvue, United States, (6)EcoBeautyScore Association / Beiersdorf AG, Germany*

The EcoBeautyScore (EBS) Association*, comprising over 70 global cosmetic companies and associations, has developed a unified environmental footprint measurement and scoring system for cosmetic products over the past three years. This system is based on Life Cycle Assessment (LCA), recognized by the European Commission (EC) as the most effective method for assessing and comparing the environmental footprint of products and services. The LCA methodology aligns with the Product Environmental Footprint (PEF) guideline initiated by the EC in 2013. Moreover, the method was enhanced to suit the specificities of the cosmetic industry.

The Association members recognized a need to develop more comprehensive databases to improve coverage for environmental characteristics of cosmetic ingredients to make PEF applicable to cosmetic products. This need is driven by the large portfolio of diverse ingredients used in cosmetic product formulation, and particularly for mid-point characterization factors (CFs) to assess end-of-life ingredient impacts, which is a significant differentiator among EBS results for cosmetic products.

The CF is the product of fate (FF), exposure (XF) and effect factor (EF) values. The Association concentrated efforts on developing substance-specific EFs because they are the most influential factor for determining CF, described in a separate presentation. The FF and XF values are data intensive to derive, needing a minimum of five physical/chemical and four environmental characteristics. Because of the large ingredient portfolio used in cosmetic products and the smaller relative influence of FF and XF, a semi-specific approach to determine FF and XF was developed using a read across and clustering method. Semi-specific FFs and XFs, and specific and semi-specific EFs were combined to create a robust CF database for cosmetic ingredient end-of-life assessment.

We created a matrix of four semi specific clusters for the product of XF and FF values, based on ingredient biodegradability and bioaccumulation properties. This generated data for 30% of the Association s priority ingredients when combined with substance-specific EF values. When no such EF value was available, four semi-specific EFs were used to obtain 16 clusters, enabling CF estimation for additional priority ingredients. This approach produced a significant improvement in data coverage for ingredients contributing most to the end-of-life environmental footprint of cosmetic products.

Disclaimer/Disclosure: The EcoBeautyScore initiative started as a consortium in 2021 and turned into an association (under the Belgium Law) in 2024.

5.08.P-We432 How the Effect Factor Calculation Method Developed by the EcoBeautyScore Association Improves the Robustness of Freshwater Ecotoxicity Impact Assessment of Cosmetic Products in Life Cycle Assessment

*Sophie Achigar[1], Alessio Aufoujal[1], Laurent Gilbert[2], Stephanie Johann[1], Mathilde Kolenda[1], Sacha Laruelle[3], **Jacques L'Haridon**[2], Olena Onyshchenko[4], Jennifer K. Saxe[5], Pascal Seel[6], Harald Streicher[6] and Jad Zoghaib[2], (1)EcoBeautyScore Association / Quantis, France, (2)EcoBeautyScore Association / L'Oreal Recherche & Innovation, France, (3)EcoBeautyScore Association / LVMH Recherche Parfums & Cosmetiques, France, (4)EcoBeautyScore Association / Henkel AG & Co. KGaA., Germany, (5)EcoBeautyScore Association / Kenvue, United States, (6)EcoBeautyScore Association / Beiersdorf AG, Germany*

The EcoBeautyScore (EBS) Association*, comprising over 70 global cosmetic companies and professional associations, has developed a unified environmental footprint measurement and scoring system for cosmetic products over the past three years. This system is based on Life Cycle Assessment (LCA), recognized by the European Commission (EC) as the most effective method for assessing and comparing the environmental footprint of products and services. The LCA methodology builds on the Product Environmental Footprint (PEF) guideline initiated by the EC in 2013. Moreover, the method was enhanced to suit the specificities of cosmetics. One of the key topics subject to adjustments from PEF in the EBS methodology is the freshwater ecotoxicity impact assessment method.
For freshwater ecotoxicity, the PEF method prescribes the use of the USEtox© 2.1 model adapted by the Joint Research Center (EC). There is a consensus within the EBS Association that the prescribed USEtox model for freshwater ecotoxicity and the corresponding characterization factors (CF) (as part of the EF 3.1 method package) have limitations in their ability to generate robust environmental scores for cosmetics, suitable for meaningful differentiation among products, which is the main objective of the Association. The actions taken within the EBS Association to tackle these limitations and improve the robustness of the freshwater ecotoxicity CF led to the development of an alternative method, called MSS HC5, to calculate the Effect Factor (EF) component of the CF value. The method calculates the EF component of CF using the 10% response levels in chronic aquatic toxicity tests (EC10chr, used preferentially) or no adverse effects concentrations (NOECs) of the Most Sensitive Species (MSS) determined from available chronic studies or extrapolated from acute toxicity studies, if necessary. Data for the three standard trophic levels (algae, invertebrates and fish), are used to approximate the Hazard Concentration for 5% of all freshwater species (HC5). This alternative method, which sensitivity analyses indicate is equally or more robust than the PEF-prescribed method using an HC20 derived from a Species Sensitivity Distribution (SSD), are shown, as well as its advantages for the cosmetics sector and potentially other sectors motivated to improve reliability of freshwater ecotoxicity impact assessment in LCA.

Disclaimer/Disclosure: The EcoBeautyScore initiative started as a consortium in 2021 and turned into an association (under the Belgium Law) in 2024.

5.08.P-We433 Applying Product Biodiversity Footprint Method To Cosmetic Sector: Case Study Of L'Oréal

Magdalena Maria Czyrnek Deletre[1], *Margot Rigal*[1], *Alexis Burguburu*[1], *Emma Garrigues*[1], *Aude Dupin*[1], *Jacques L'Haridon*[2], *Kaiwei Wang*[2] *and Guillaume Neveux*[1], *(1)I Care by Bearing Point, France, (2)L'OREAL, France*

As biodiversity declines globally, it is essential to assess the biodiversity footprint of individual products, industrial sites, and at the company level. There are many different approaches in use, but no consensus exists on which should be endorsed.
I Care has been working since 2017 on developing a suitable methodology to assess the impact on biodiversity of products. L Oréal participated in the development of this methodology, called Product Biodiversity Footprint (PBF), and was associated with Sayari in its publication in 2019. It is essential for L Oréal to develop an understanding of the biodiversity footprint at product level to support eco-design of cosmetics with the aim of preserving or even restoring biodiversity, as well as exploring how it connects to corporate commitments..
In 2024, the PBF methodology underwent significant changes by incorporating Mean Species Abundance metrics to assess biodiversity loss. Based on the 2019 Global Assessment report from the Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services, a new approach for weighting biodiversity pressures was introduced.
The PBF methodology allows to evaluate the impact on biodiversity of different practices and actions introduced at the product level, by comparing a reference product to variants of this product. Three cosmetic products were studied to demonstrate the interest of the revised methodology: a shampoo, a shower gel, and a deodorant. The analysis was also conducted at the ingredient level (glycerin, sodium laureth sulfate, cocamidopropyl betaine, ammonium lauryl sulfate and ethanol) and agricultural feedstock level (palm crop, coconut crop, soybean crop and beetroot crop) to better understand biodiversity impacts. The results are encouraging in guiding future choices among various alternatives of cosmetic products under development, also taking their biodiversity footprints into account.

5.08.P-We434 Development of Extinction Risk Maps for Terrestrial Species Due to Climate Change

Ruri Hashimoto[1], *Akiko Hirata*[2], *Haruka Ohashi*[2], *Longlong Tang*[3], *Runya Liu*[1] *and Norihiro Itsubo*[1], *(1)Waseda University, Japan, (2)Forestry and Forest Products Research Institute, Japan, (3)National Agriculture and Food Research Organization, Japan*

According to IPBES report, the impact of climate change on biodiversity is extremely severe, and an effective tool is required to address the ongoing loss of biodiversity. Specifically, it is necessary to quantitatively evaluate the impacts from climate change on biodiversity worldwide and to assess the extinction risk of species in the future at a high spatial resolution.
Recently, a study estimated spatially on the impacts of climate change to biodiversity in each taxonomy group. This study used the Potentially Affected Fraction (PAF) as an indicator to estimate the impacts, without directly addressing potential extinction risks. Additionally, the TNFD guidelines emphasized the importance of evaluating regional biodiversity loss with higher resolution. On the other hand, in LCIA, little progress has been made in developing biodiversity damage factors at the grid level to reflect spatial differences caused by climate change. Given that biodiversity and environmental factors vary regionally, it is essential to evaluate the potential extinction risks of species at the grid level. Such evaluations enable a more accurate understanding of the extent to which specific regions and species are at risk due to climate change, forming the basis for developing appropriate conservation strategies.
Therefore, this study aims to examine how future climate change scenarios will affect the extinction risk of terrestrial species and to estimate the distribution of global extinction risks and climate change-induced damage factors at the grid level.
Specifically, species distribution model (SDM) was used to evaluate a total of 8,428 terrestrial species across five taxonomic groups. Habitat changes and losses due to climate change were simulated under SSP3-RCP7.0, a sustainable future scenario, and extinction risks were estimated from changes in the species' habitat areas. The estimated extinction risks were then allocated to grid levels to illustrate the spatial distribution of extinction risks. Through this approach, the study aims to identify regions in urgent need of conservation measures and contribute to the development of future biodiversity conservation strategies.

5.08.P-We435 Location-Based Global Biodiversity Extinction Damage Factor Development—Under Future Land Use Change Impact

Runya Liu[1], *Akiko Hirata*[2], *Haruka Ohashi*[2], *Longlong Tang*[3], *Kousuke Terasaki*[4], *Tetsuya Matsui*[2] *and Norihiro Itsubo*[1], *(1)Waseda University, Japan, (2) Forest Research and Management Organization, Japan, (3) National Agriculture and Food Research Organization, Japan, (4)MS&AD InterRisk Research*

& Consulting, Inc., Japan

Following the establishment of the Kunming-Montreal Biodiversity Framework, there has been a significant global trend in the assessment of ecosystems and biodiversity. Nevertheless, the current tools and knowledge for evaluating the impact from land use to biodiversity still demonstrate significant gaps that require enhancement. Advancements in assessment methodologies and precision will further support the realization of global Natural-Positive objectives.

We have significantly optimized the existing methodologies utilized for assessing biodiversity, enhancing their accuracy to ensure that users of Life Cycle Assessment (LCA) can perform evaluations that are specific to particular locations in future applications. In this research, we have further expanded the coverage scale to encompass an impressive total of 400,000 species across five distinct taxa. These findings build upon our previous work, which concentrated on the evaluation of 6,000 species and future predictions based on land use data characterized by the CIMP6. Conducting assessments at the species level necessitated the integration of a machine learning model that incorporates detailed species-level information. The results of our analysis extend from the present day to the year 2100, under various future scenarios. In contrast to earlier research, we have made an effort to introduce the extinction rate indicator derived from the Planetary Boundaries report, integrating it into the life cycle impact assessment model. This innovative approach not only allows for a more comprehensive interpretation of the assessments but also facilitates the evaluation process to align with policy-oriented standards. To address the anticipated demands of future users, we have accurately segmented the damage factor on both a high-resolution spatial scale and a country-specific numerical scale for certain regions, even refining these scales to a prefectural level in some instances.

5.08.P-We437 Use of Satellite Data and Spatially Differentiated Characterization Factors for Biodiversity Impact of Land Use Due to Wind Turbines

Maeva Lavigne Philippot[1]*, Dominik Huber*[1]*, Christian Mikovits*[2] *and Maarten Messagie*[1]*, (1)Vrije Universiteit Brussel, Belgium, (2)University of Natural Resources and Life Sciences, Vienna, Austria*

The impact of wind energy deployment on biodiversity mostly originates from habitat loss and disturbance. The assessment of the impact of land use (LU) on biodiversity necessitates spatial differentiation. To be able to assess the LU impact of wind turbines (WT), detection of LU change thanks to satellite data is necessary. However, there is a mismatch between the LU types in life cycle impact assessment (LCIA) and satellite data. In order to assess the European WT fleet, a model taking into account spatial explicit characterization factors (CF), satellite data and WT parameters is needed. Our model needs the WT location, capacity, hub height and rotor diameter as user inputs. Corinne Land Cover 2018 100mx100m dataset is consulted to evaluate pre-installation LU type. For each ecoregion of Europe, land use type from Corinne dataset and land use type and intensity data from life cycle impact assessment (LCIA) method are compared to obtain co-occurrence matrices. The area of surface of change of European WT fleet is identified thanks to the analysis of Copernicus Sentinel-2 satellite images from 2015 to 2023. Correlation between this area and WT capacity, or hub height, or rotor diameter will be evaluated, to have a parametric LCI, thanks to a surface change file. The change due to road construction is based on legal minimal distance to road for construction of new WT in European countries. For occupation, the lifetime of the WT is used, and its influence will be assessed in a sensitivity analysis. The new model will be open-source and also integrated in an online interactive map that optimizes the position and characteristics of WT and shows the diverse impacts of WT, including an LCA model as well as impacts on noise, landscape, among others. The co-occurrence matrices match, in some ecoregions, still need to be studied in detail because the different resolutions and time of data collection of the datasets, as well as specific patterns of ecoregions may be the source of differences. The surface area change was analyzed for more than 78,000 WT in Europe. Depending on the distance buffers, concave hulls and convex hulls assessed around the WT, between 22m²/WT and 152m²/WT are changed after WT construction. This model will be used to evaluate for the first time the European WT fleet impact on biodiversity in terms of potential disappeared fraction (PDF) of species per unit of energy produced.

Disclaimer/Disclosure: This project has received funding from the European Union s research and innovation programme Horizon Europe under the grant agreement No. 101083460.

5.08.P-We438 Calculation of Characterization Factors for Life Cycle Impact Assessment of Biocides Using USEtox

Elisa Arteaga Prieto *and Karel Van Acker, KU Leuven, Belgium*

Biocides are chemicals used to control detrimental organisms for products. While beneficial, they pose risks to human health and ecological balance. Risk assessment is necessary and legally required before market entry. Incorporating a life cycle perspective in their analysis offers a key advantage: it allows

comparing benefits of extending a product s lifespan during storage and use with the environmental impacts of resource consumption, manufacturing, and spoilage. Life Cycle Assessment (LCA) is a widely used methodology for such analysis. However, LCA databases lack sufficient data on chemicals due to the vast number of substances, making it difficult for companies and researchers to fully leverage LCA. Specifically, quantifying biocides impacts on human toxicity and ecotoxicity is constrained by this data gap. This research investigates whether characterization factors for biocides can be calculated using readily available data from existing research, development processes, or other sources.
The calculation of characterization factors (CFs) relies on three components as defined by the USEtox methodology: Fate Factor, Exposure Factor and Effect Factor. The required data include physico-chemical properties, propagation routes, and hazardousness. Previous research suggests that the scarcity of CFs for chemicals is largely due to a lack of experimental data necessary for their computation. This study proposes to explore readily accessible sources, such as data used in risk assessments, enabling companies to calculate CFs and perform LCA.
The study focuses on calculating CFs for PT 6 biocides (preservation during storage). The active substance used as a case study is a mixture of C(M)IT and MIT. The primary source of data for the calculation of effect and exposure factors is the Authority Report for the review program of existing active substances (Directive98/8/EC). The fate factor is derived using the USEPA EPI Suite tool. As validation process, the methodology will be tested on commonly known VOCs such as formaldehyde, benzene, and ethylene glycol to identify potential errors and uncertainties.
This study aims to determine whether private entities can independently calculate CFs. Given the diversity of chemical substances, it is impractical to centralize their CF development. Allowing chemical producers to calculate CFs independently can empower them to assess the environmental impact of their products efficiently and support sustainable market entry.

5.08.P-We439 Environmental Impact Assessment of Nanotechnology Using Life Cycle Assessment (LCA)

Byung-tae Lee, *Hyojung Choi and Keun-bae Yu, Gwangju Institute of Science and Technology, Korea, Republic of*

Nanomaterials, as a key area of nanotechnology, have gained significant attention for their unique functionalities, driving advancements in diverse scientific and industrial fields such as medicine, semiconductors, and energy. Simultaneously, the potential human and ecological toxicity of nanomaterials, arising from their size and surface properties, has led to the development of risk-based safety management policies and related technologies. Recently, beyond safety considerations, there has been a growing focus on assessing the environmental impacts of nanomaterials across various categories, including resource and energy consumption, carbon and greenhouse gas emissions, and the release of environmentally hazardous substances. These assessments aim to evaluate and ensure the sustainability of materials and technologies. The sustainability of nanomaterials appears to be properly assessed using the life cycle assessment (LCA) framework, which evaluates impacts across the entire life cycle, from production to disposal. This study reviewed research cases to establish the application of LCA for nanomaterials. Key data sources, inventory utilization, assessment categories, and major findings in LCA studies on nanomaterials were systematically examined. To integrate nanotechnology within the LCA framework effectively, three primary research areas need to be addressed. First, it is essential to adopt appropriate functional units that account for all additional functionalities of manufactured nanomaterials (MNMs) compared to their bulk counterparts. Second, the development of life cycle inventory (LCI) data for the production of MNMs is crucial, along with methodologies to qualitatively and quantitatively model the eventual release of MNMs throughout their lifecycle. Third, characterization factors for released MNMs must be developed, as they are critical for incorporating MNM emissions into life cycle impact assessment (LCIA). The proposals outlined in this study will contribute to establishing a framework for assessing the safety and sustainability of nanomaterials, advancing their responsible development and application.

5.08.P-We440 New Advances to Assess Biodegradation and Toxicity of Alternative Environmentally Friendly Polymers

Anne-Leila Meistertzheim[1], *David Leistenscheider*[1], *Lena Philip*[1], *Isabelle Calves*[1], *Leila Chapron*[1], *Edouard Lavergne*[1], *Karine Lebaron*[1], *Boris Eyheraguibel*[2], *Franck Lartaud*[3] *and Jean-FranCois Ghiglione*[4], *(1)Plastic At Sea, Banyuls-sur-mer, France, (2)Universite Clermont Auvergne, Clermont Auvergne INP, CNRS, Institut de Chimie (ICCF), France, (3)Sorbonne Universite, CNRS, Laboratoire d Ecogeochimie des Environnements Benthiques (LECOB), (LOMIC), Observatoire Oceanologique de Banyuls, France, (4)Sorbonne Universite, CNRS, Laboratoire d Oceanographie Microbienne (LOMIC), Observatoire Oceanologique de Banyuls, France*

The inherent toxicity linked to plastic ubiquitous presence in the environment has received a growing interest in the last decades. Even though laws, policies and scientific projects addressing plastic pollution and its impact have recently flourished, very few concerned plastic risk assessment (i.e. linking plastic exposition and their effects on ecosystems) taking into account conventional or biobased, recycled or biodegradable polymers. Our objective was to develop new methods to assess plastic end-of-life on marine environment based on biodegradability assays and toxicity tests on marine organisms in order to develop environmental impact indexes relevant for Life Cycle Analysis.
On the basis of field and laboratory experiments, we tested different conditions to follow the biodegradation of polymers by natural marine bacterial communities (named plastisphere). We tested several media and conditions to measure the biodegradability of biosourced and petroleum based polymers comparatively to cellulose standard, in real marine and aquatic conditions. On the other hand, we developed methods to measure the impacts of plastics at different trophic levels of the marine environment, based on ecotoxicological studies on communities in their natural environment at the molecular, cellular, organ, individual and population levels. The methodological limits of toxicity tests, generating a partial assessment of the impact of microplastics on marine organisms were tested including several limits such as concentration, size, shape, chemical composition of plastics. Finally, relevant standards were tested to evaluate plastic toxicity to assess the effective risk of alternative and conventional plastics in marine biodiversity.

5.08.P-We441 Evaluation of the USEtox Method for Use in the Sustainability Assessment of Selected Packaging

Katja Wack[1]*, Manfred Tacker*[1] *and Michael Schwingshackl*[2]*, (1)Circular Analytics TK GmbH, Austria, (2)FH Technikum Wien, Austria*

The European Commission has developed the Product Environmental Footprint (PEF) to assess the impacts of a product using a standardised and harmonised LCA-based approach. The concept contains specific rules for the assessment of impacts in 16 categories based on existing methods. For the toxicity-related categories - human cancer toxicity, human non-cancer toxicity and freshwater ecotoxicity - the PEF refers to the science-based consensus model USEtox. This model calculates the effects of chemicals individually based on fate, exposure, and the impact on humans or ecosystems. The European Commission subjects all methods used in the PEF to a robustness assessment that includes a completeness check, a sensitivity analysis and a consistency check. Based on this robustness assessment, this work tests the applicability and robustness of the USEtox method for assessing the toxicity of the packaging materials used in a yoghurt cup to evaluate whether the method is suitable for the toxicity assessment of packaging materials, particularly food contact materials. For the completeness check, the latest USEtox version (v2.13) is analysed, and the method's approach and results are compared with different approaches of toxicity assessments. In the sensitivity analysis, the results of different USEtox versions are calculated to assess the dependence of the results on the differences in the methods. In the third step, a consistency check is carried out by comparing the results with various ecoinvent versions to analyse the consistency of the data. The results of the assessment show that USEtox differs from other approaches in some aspects, mainly attributable to the hazard-based concept. Although this approach is scientifically based, it is only suitable for assessing the toxicity of packaging such as the yoghurt cup to a limited extent, as it does not consider the utilisation phase or actual exposure. In addition, the results vary depending on the USEtox version and database used, which makes it difficult to draw reliable conclusions. Errors in the database affecting certain chemical streams have also recently been uncovered, suggesting that a careful review of the data used is also needed. Therefore, further research is needed to resolve these uncertainties.

5.08.P-We442 Refining Ecotoxicity Assessment in Life Cycle Assessment: Bridging Data Gaps for Comprehensive Environmental Impact

Daniel Alexandre Bruno[1]*, Ian Vazquez-Rowe*[2]*, Susana Loureiro*[1] *and Paula Quinteiro*[1]*, (1)Centre for Environmental and Marine Studies (CESAM), University of Aveiro, Portugal, (2)Peruvian Life Cycle Assessment and Industrial Ecology Network (PELCAN), Pontificia Universidad Catolica del Peru (PUCP), Peru*

Chemical substances released into the environment are distributed across the various environmental compartments based on their physicochemical properties and interactions. The presence of these substances has been shown to cause ecotoxicological impacts in different environmental compartments, with the extent of these impacts depending on factors such as substance fate, exposure -environmental concentrations, residence time, the mode of action and the sensitivity of the species and communities- and environmental effect on species.
A product's life cycle begins with raw material extraction and energy generation, followed by production, packaging, distribution, use, maintenance, and ultimately recycling, reuse, recovery, or disposal occurring

chemical emissions to soil and water in each stage.
Ecotoxicity is one of the impact categories covered in the life cycle assessment (LCA) methodology. It involves translating the total environmental emissions of chemicals associated with the production, use, and end-of-life of a good or service into a measure of their potential ecotoxicological impact. However, the current available life cycle impact assessment methods address only a limited amount of chemicals, leaving a significant proportion of chemicals to which ecosystems may be exposed unassessed.
This study presents a systematic review to understand how ecotoxicity has been addressed within the LCA. It explores the development of environmental impact mechanisms on water and soil, identifies the substances and organisms considered, and identifies the species and extrapolation procedures employed in the absence of data. Furthermore, the study proposes future directions for enhancing LCA and ecotoxicity assessment practices.
The limited availability of toxicity data for environmental chemicals highlights the importance of this study. By providing a comprehensive analysis of the current limitations of LCA and ecotoxicity impact indicators, this study highlights the need to increase the life cycle inventory datasets of substances' ecotoxicity and improve the interlink between ecotoxicity concentrations and organism resilience.

Disclaimer/Disclosure: This study is funded by the PRR - Recovery and Resilience Plan and by the NextGenerationEU funds at Universidade de Aveiro, through the scope of the Agenda for Business Innovation InsectERA (Project no. 20 with the application C644917393-00000032). The authors would like to acknowledge the Portuguese Foundation for Science and Technology (FCT)/MCTES for the financial support to CESAM (UIDP/50017/2020+UIDB/50017/2020 + LA/P/0094/2020), through national funds. Thanks also to PRR for the research grant granted to Daniel Bruno (BI/UI64/10456/2024). Paula Quinteiro also acknowledges the research contract 2023/06946/CEECIND.

5.09 LCA for Decision-Making, Communication and Reporting

5.09.T-01 Using Absolute Environmental Sustainability Assessment and Mid-To-Endpoint Modelling to Identify the Most Relevant Impact Categories to Include in a Building LCA

*Anders Bjorn[1], **Manja Nørrekær Lund**[1] and Anna Kristina Schjerbeck[2], (1) Technical University of Denmark, Denmark, (2)Green Building Council Denmark, Kobenhavn K, Denmark*

The construction sector in Europe is increasingly documenting its impact on climate change through life-cycle assessment (LCA). The movement is bolstered by legislation mandating the calculation of greenhouse gas emissions from new buildings. While there has been a strong emphasis on assessing climate change impacts, other environmental impacts have often been neglected. This study identifies the most relevant midpoint impact categories to include in LCAs on buildings through two novel complementary approaches. The two approaches assess relevance based on the severity of impacts: absolute environmental sustainability assessment (AESA) and mid-to-endpoint contribution analysis. The approaches are applied to 40 residential buildings covering 370,000 m2. For the AESA approach, impact categories for which case buildings exceeded their allocated carrying capacity were considered relevant, while the impact categories contributing most to endpoint damages were considered relevant for the and mid-to-endpoint approach. The study's characterization factors and allocation principles were tested in a robustness analysis. Climate change, land use, and fine particulate matter were relevant according to both approaches and showed a high robustness towards changes in the set of characterization factors and allocation principles. Freshwater ecotoxicity, freshwater eutrophication, human carcinogenic toxicity, and mineral use were less robust considering the choice of life-cycle impact methods and allocation principles. Our approach aims to help the building industry find a middle ground between only reporting LCA results for climate change, which could lead to burden-shifting, and systematically reporting LCA results for all midpoint impact categories, which could lead to decision paralysis.

5.09.T-02 Allocation in ISO, GHG Protocol, and Environmental Footprints

***Tomas Ekvall**[1], Mats Berglund[2], Elias Hallack[2], Sofia Poulikidou[3], Lisa Rasmusson[2], Ellen Riise[4] and Yulia Liu[5], (1)Tomas Ekvalol Research, Review & Assessment, Sweden, (2)SKF, Sweden, (3)Hoganas, Sweden, (4)Essity, Sweden, (5)Chalmers University of Technology, Sweden*

The flora of ISO standards related to life cycle assessment (LCA) is growing organically. Meanwhile, the

Greenhouse Gas Protocol has become a de facto standard for many industrial companies, and the EU has established Environmental Footprint as the framework to use in Europe. These documents all refer to the allocation hierarchy in ISO 14044, but present a variety of interpretations and even deviations from this hierarchy. A line of conflict concerning the interpretation of system expansion is apparent; however, the standards also diverge in the interpretation of allocation that reflects underlying physical relationships or other relationships.

We present the points of conflict between the standards. We also present ambiguous points in the documents. We discuss the accuracy of different interpretations of the allocation hierarchy as well as their relevance to decision-making. Finally, we discuss changes that can be made in the allocation hierarchy to make LCA a more effective tool in decision-making.

5.09.T-03 Module D in Environmental Product Declarations (EPDs): Sorting the Weed of Misinterpretation

*Andreas Ciroth and **Ashrakat Hamed**, GreenDelta GmbH, Germany*

Communicating and reporting Module D in Environmental Product Declarations (EPDs) is recognized as challenging, especially for individuals unfamiliar with Life Cycle Assessment (LCA). Module D, as defined in the EN 15804+A2 standard, involves hypothetical environmental credits rather than actual life cycle impacts. As a result, misleading impressions of environmental benefits may unintentionally be created. For example, negative values from Module D can make a product appear more environmentally friendly than it actually is when compared to the concrete stages A1 to C, which cover processes from raw material extraction to disposal. Challenges associated with Module D modeling are introduced by differences in recycling practices, regional variations, and inconsistent data quality. Additionally, reliance on general assumptions rather than location-specific data complicates the alignment of LCA objectives with practical applications. Since Module D is not an actual life cycle stage but instead accounts for credits from recycled or reused materials in other life cycles, confusion among non-LCA stakeholders is often increased.

When EPDs for products such as steel pipes, hot-rolled steel bars, and ready-mix concrete were analyzed, greater variability is observed in Module D values compared to those of Modules A1-A3. The importance of a standardized LCA approach is therefore highlighted to ensure that results are consistent and comparable. Practical aspects of applying Module D in EPDs include defining end-of-life waste scenarios, assessing material quality differences, and recycling. This paper aims to provide guidance on simplifying Module D modeling, with an emphasis on standardized LCA practices to effectively address data and communication challenges. By ensuring transparency and minimizing the risk of greenwashing, more reliable sustainability information for decision-making and policy compliance can be supported.

5.09.T-04 Decision-Oriented Choice for Electricity Supply Modelling in Attributional LCA: Location-Based or Market-Based Approach?

***Anne Grau** and Aindrias Lefevere-Laoide, EDF, France*

Most products consume electricity, either for their production or their use phase. Therefore, for assessing their life cycle impacts through an attributional LCA, accurately modelling their electricity supply is important. Two main accounting approaches are used in LCAs: (1) the location-based approach, considering territorial electricity mixes (either at the national or at the regional level) and (2) the market-based approach considering market instruments such as Energy Attribute Certificates (EACs, e.g. Guarantees of Origin (GO) in Europe) complemented by residual mixes (as provided for instance by the Association of Issuing Bodies (AIB) in Europe).

As an introduction, basic physics of electricity production and distribution will be presented. Then, both the location-based and the market-based approaches will be presented, and their main pros and cons discussed. Based on this analysis, we will propose guidelines to select an approach that better matches the objectives of most Industry attributional LCAs, which are: product eco-design, product comparison and publication of environmental declarations.

In most cases, the use of the location-based approach avoids accusations of greenwashing and ensures a consistent use of datasets in the foreground and background of an LCA, whereas the use of the market-based approach can face accusations of resource shuffling and inconsistencies within one LCA (e.g. geographical and temporal inconsistencies between electricity production and consumption and double counting of the energy supply processes covered by EACs).

As a conclusion, we can say that different accounting approaches serve different purposes and before choosing an accounting method, one should be clear about what is the goal and scope of its LCA. For product eco-design and comparison, the location-based approach should be favored, because it provides a better understanding of the product value chain processes and their related environmental impacts and the potential impact transfers for different product design options. However, the market-based approach can be used for communication purposes, provided the EAC systems evolve to encourage better matching of the physical reality of electricity production and consumption. Meanwhile, it is of upmost importance that the electricity supply modelling hypotheses and implementation are transparent to the recipients of the LCA reports, to allow for better understanding and comparability.

5.09.P-We443 From Opportunities of Industrial LCA Usage to Data Specification Challenges: The Example of Winter Sport Hard Goods

Ulrike Kirschnick[1]*, Paul Domberger*[1]*, Anita Hochreiter*[2] *and Ewald Fauster*[1]*, (1)Processing of Composites Group, Montanuniversitaet Leoben, Austria, (2)Atomic Austria GmbH, Austria*

The motivation, chances and challenges of using Life Cycle Assessment (LCA) in research and industry are different with a lack of studies emphasizing on specificities of industrial usage. Within multiple challenges of using LCA in industry, data collection internally and from external suppliers proves a major obstacle. Data specifications are a necessity within methodological frameworks and a key aspect in decision-making fostering a company s journey towards more sustainable production.

This study aims to elaborate on the motivation, status quo and future application of LCA in the winter sport industry in Austria, which has been selected as an example which is representative for many small and medium enterprises (SME) in the European legal context. Additionally, options and limitations to collect, consider and use specific data from suppliers in product LCA are discussed using two different background databases.

Bilateral interviews have been conducted with five companies comprising open questions to i) determine the general situation and attitude towards sustainability, and ii) the status quo of LCA in the companies, as well as iii) a SWOT analysis. Concerning data specification, a collection template has been developed, filled and discussed with key suppliers for an examplary intermediary product; an injection-molded part made from polypropylene. The environmental impacts are calculated for a default and a specified scenario using Environmental Footprint (EF3.1) and ecoinvent 3.10 cut-off databases.

The interviewed companies shared similar motivations and usage of LCA results, which is currently mostly applied for internal purposes, such as deepening the understanding of production processes and product development, and only occasionally used for sustainability reporting and to communicate with external stakeholders. The shared challenges are lack of data availability, limited comprehensiveness of standard, and uncertainty on requirements and formats for external communication, including (future) legal development.

The data specification excise demonstrated that not only data collection but especially data analysis and implementation in the LCA model require additional effort with differences in feasibility between the databases. On the other hand, the gain in accuracy provides a more differentiated picture for the 16 impact categories of the EF3.1 impact assessment method and promotes communication and collaboration along the value chain.

5.09.P-We444 Life Cycle Costing Aligned with Life Cycle Assessment as part of Life Cycle Sustainability Assessment: Flexibility and Challenges Depending on the Decision-Making Context

Till M. Bachmann[1]*, Jonathan van der Kamp*[1]*, Marco Bianchi*[2]*, Hanna Pihkola*[3] *and Mateo Saavedra del Oso*[4]*, (1)European Institute for Energy Research (EIFER), Germany, (2)TECNALIA, Basque Research and Technology Alliance (BRTA), Spain, (3)VTT Technical Research Centre of Finland Ltd, Espoo, Finland, (4)Center of Excellence for Packaging Sustainability (CEPS), Division of Packaging Materials, Finland*

Existing life cycle sustainability assessments (LCSAs) suffer from a lack of comprehensiveness, consistency and practical tools for implementation. A robust and operational methodology for LCSA of products was developed in the EU-funded ORIENTING project (www.orienting.eu; 2020-2024) in which life cycle costing (LCC) covers the economic dimension. An LCC methodology was developed that (a) suits LCSA purposes not tailored to a specific type of product, (b) is aligned with the environmental Life Cycle Assessment (LCA) part of LCSA, (c) explicitly addresses double counting notably when using the same data as in the Life Cycle Inventory (LCI), (d) is applicable to different stakeholder needs and (e) addresses externalities. While it was designed for LCSA, it can also be used stand-alone.

To achieve consistent decision-making, an environmental LCC approach is adopted, i.e. an LCC aligned with LCA. This includes distinguishing the same set of life cycle stages and the consideration of double counting by taking either the so-called own realities position or adjusting LCA (e.g. disregarding abiotic resource uses or distinguishing emissions with and without costs).
Decision context-specific flexibility is implemented in terms of considering discounting or positive cash flows and thus the choice of the economic indicator. This also depends on the defined goal and scope, and thus the chosen stakeholder perspective. Three stakeholder perspectives are distinguished: the producer, the consumer and society.
The decision context can also influence data collection strategies, as exemplified by how different stakeholders would fill the proposed cost breakdown structure.
The LCC methodology was applied in two case studies, one on the business-to-business (B2B) product beverage carton package and one on the consumer product outdoor wool jacket . Amongst other things, the case studies demonstrate how data confidentiality can impact the way in which results can be presented. In the jacket case, the results of a contribution analysis could be made public. In the beverage carton package case, results based on primary data could not be shared for confidentiality reasons (especially prevailing for B2B products), while results based on publicly available data were misleading and thus not shared. This highlights that while LCC is well suited for internal decision making, public communications might be hampered.
The study has already been published: https://rdcu.be/dOKRe.

5.09.P-We445 Knowledge Graphs for LCA: Streamlining Consistent Reporting

Didier Beloin-Saint-Pierre[1]*, Alexander Kirsten*[1]*, Joana Francisco Morgado*[1]*, Daniel Lachat*[1]*, Jan Grau*[2]*, Kimberly Garcia*[2] *and Roland Hischier*[1]*, (1)EMPA - Swiss Federal Laboratories for Materials Science and Technology, Switzerland, (2)University of St. Gallen, Institute for Computer Science, Switzerland*

Recent developments of the European regulation (e.g. corporate sustainability reporting directive) are creating pressure to increase the capacity to make more life cycle assessment (LCA) studies in the near future even if there is now a shortage of experts and consultants to do this work. We therefore need to find faster ways to carry out and review LCA studies for organisations and products.

Meanwhile, many associations and institutes have proposed various standards for environmental assessments (e.g. product environmental footprint) or frameworks to exchange data (e.g. pathfinder initiative). The differences between these standards and frameworks hinder simple exchange of consistent data between companies along value chains.

In this context, it is interesting to see that most of the environmental assessment standards are inspired by the foundational work presented in the ISO 14040-14044 documents. This common basis can help in identifying common rules that have been used by experts and consultants to check if different data sources and LCA studies can be consistently compared or combined to create models of various value chains.

We thus propose to build knowledge graphs (KGs) for LCA standards and related databases utilising the common key concepts defined in the ISO 14040-14044 documents. The KGs provide a machine readable and understandable description of rules that need to be followed to ensure that LCA studies are carried out consistently even for different guidelines. These KGs can then be used to automatically make consistency checks and translate LCA studies in the format of different standards (e.g. respecting specific disclosure requirements).

Two connected KGs are created to enable the consistency checks and translation of LCA studies. The first KG lists the rules of LCA standards that need to be checked so that assessed environmental impacts of organisations, products or services are valid for a selected assessment context. A second KG informs on the content and formats of most LCA data sources (e.g. studies and databases). The two KGs are then connected to enable the evaluation of the consistency between different studies that might be considered comparable. Moreover, the KGs allow translating the results of such studies to different formats.

The developed KGs thus address key challenges that currently hinder exchanges of consistent LCA data between stakeholders of supply chains, which will hopefully lead to more consistent reporting.

5.09.P-We446 Recent Advances and Future Prospects of Optimization-Based Decision Support in LCA using PULPO
Fabian Lechtenberg[1] *and Gonzalo Guillen-Gosalbez*[2]*, (1)Polytechnic University of Catalonia, Spain, (2) ETH Zurich, Switzerland*
Life Cycle Assessment (LCA) has become a cornerstone of environmental decision-making. However, the complexity of contemporary sustainability challenges raises the need to go beyond simple static production system assessments. To address this, advanced tools such as dynamic and scenario assessments have been developed to extend LCA s capabilities, but gaps remain particularly in optimization-based decision support.
To bridge this gap, we developed PULPO, a method and tool that effectively adds Life Cycle Optimization (LCO) to the LCA toolbox, enabling practitioners to identify optimal production system maximizing performance in some impact categories. This approach eliminates the need for exhaustive scenario screening by streamlining the process of finding the best configurations, enabling the automatic exploration of vast numbers of scenarios in short CPU times. Beyond this, PULPO supports advanced considerations such as system constraints, including capacity limits, material availability, and regulatory

or environmental flow restrictions, which traditional LCA approaches often struggle to incorporate. Additionally, PULPO facilitates the simultaneous variation of both foreground and background processes, capturing essential feedback loops crucial for emerging technologies and large-scale decision-making. In this contribution, we present the latest advancements in PULPO, detailing updates that enhance user experience and computational features. Improvements include a simple graphical user interface for basic optimization tasks and the incorporation of integer decision-making capabilities. Through the latter, users can now specify minimum capacities for production system elements, exclude specific configurations, and generate ranked lists of candidate solutions. These enhancements make PULPO more accessible and powerful, providing decision-makers with the tools to answer previously unsolvable questions.
We believe that PULPO s open-source framework empowers the LCA community to address complex decision-making challenges and encourages collaborative development tailored to emerging needs. This tool not only advances the practical use of Life Cycle Inventory (LCI) data but reinforces its potential to shape impactful policy and strategic decisions in environmental management.

5.09.P-We447 Methodological Diversity in Carbon Footprint Assessment: Challenge for Decisionmakers in the Packaging Sector

***Andrin Gstohl**, Tasja Hafner-Kuhn and Manfred Tacker, Circular Analytics TK GmbH, Austria*

The Corporate Sustainability Reporting Directive (CSRD) requires companies to document environmental parameters, including greenhouse gas emissions. How greenhouse gases must be accounted for is specified in more detail in the European Sustainability Reporting Standards (ESRS). There it is stated that the accounting should be compliant with the Greenhouse-Gas-protocol and emission factors from the Intergovernmental Panel on Climate Change (IPCC) should be used. In addition, the European commission s recommendation on Product Environmental Footprint (PEF) or EN ISO 14064-1:2018 standard is mentioned as the framework under which a greenhouse gas assessment shall take place. These instruments differ in scope and content, offering flexibility in their application.

For end-of-life allocation of burdens and credits for example, methods like the Circular Footprint Formula (described in PEF) or the cut-off approach can be used. LCIA methods for assessing greenhouse gases, such as EF3.1 or ReCiPe Midpoint (H), may yield different results despite both being IPCC-based. Variations in system boundaries, databases, transport distances, or end-of-life rates can significantly impact results. Therefore, it is hypothesised that even with ESRS conformity, calculations of greenhouse gases for packaging materials in different studies might lead to varied conclusions due to differing parameter settings and framework conditions.
To explore this hypothesis, life cycle analyses and carbon footprint calculations of packaging are compared in terms of coherence and the different methodological approaches are contrasted. Packaging materials (plastic, aluminium, paper, steel and glass) are then analysed regarding different parameters to show the level of differences (parameters: end-of-life allocation, LCIA-method, system boundaries).

By adjusting the parameters described, major changes in the results occur. This means that the use of different but recognised methods gives the impression of direct comparability, although the results taken out of context can result in misleading or incorrect conclusions. This pose challenges for organisations and decision makers who need to act based on the results. To create comparability and achieve the objective of the CSRD, it would be necessary to standardise the methods used to calculate the carbon footprint. Therefore, this study compares the different standards, identifies potentials, and proposes improvements in standardisation.

5.09.P-We448 A Novel Multidimensional Impact Assessment Framework to Bridge the Gap Towards a Truly Sustainable and Circular Bio-Based Industry

***Pedro Villanueva-Rey**, Lucia Gonzalez-Monjardin, Carla Carreira Garcia and Jessica Perez Garcia, Galician Water Research Center Foundation (Cetaqua Galicia), Spain*

The transition towards a bio-based economy will deliver significant environmental and economic benefits. However, bio-based production systems need to address several challenges related to biological feedstocks (e.g., seasonality, variability on physicochemical properties, or spatial distribution). In addition, there is a need for assessment methods or schemes that integrate environmental, socioeconomic and circular issues to ensure a truly sustainable performance of biological feedstocks.
In the framework of the Horizon Europe BIORECER project (101060684), it was developed a multidimensional impact framework addressing environmental performance and circularity of biological resources based on a Life Cycle Assessment (LCA) approach. The proposed framework provides guidelines on data requirements to holistically evaluate the sustainability of bio-based supply chains. Thus, existing impact assessment methodologies, sustainability standards applicable to biological

resources, and circularity indicators were reviewed to identify those requirements (up to 52) and criteria that cover both sustainability and circularity.
As a result, an integrated set of indicators intended to be used in bio-based production systems-- to practically assess the sustainability along a bio-based supply chain was established. In addition, the proposed framework will be the basis for the adaptation of current certification schemes since it includes novel criteria for certifying the sustainability of biological resources. The proposed framework has been tested and validated in four case studies covering different biological feedstocks (i.e., sewage sludge, seafood waste, organic fraction of municipal solid waste, agro-waste, and forest industry sub-products), providing promising results.

Disclaimer/Disclosure: This research has been supported by the BIORECER (No 101060684) project funded by the European Commission.

5.09.P-We449 Beyond Zero-Risk Assumption: Integrating Accident Impacts into LCA of Hydrogen Delivery Options
Tatiana D'Agostini, *Erik Smedberg and Alessandro Arrigoni, Joint Research Centre (JRC), Netherlands*
As the European Union prepares to import large quantities of low-carbon hydrogen, the optimal form of delivery remains uncertain. A previous life cycle assessment (LCA) by the Joint Research Centre of the European Commission compared the environmental sustainability of various delivery options, including gaseous hydrogen, liquid hydrogen, and chemical carriers such as ammonia, methanol, synthetic natural gas, and liquid organic hydrogen carriers. Although liquid hydrogen emerged as the most environmentally sustainable option for European territories, the study assumed a zero-risk scenario, neglecting the potential environmental impacts of accidents during delivery. This research addresses this limitation by estimating accident risks and incorporating their environmental consequences into the LCA. It is highlighted that excluding accidents from the environmental profile of hydrogen carriers provides an incomplete picture of their sustainability. We argue that a more systematic approach to integrating risk assessments into comparative LCAs is essential for informed decision-making in the transition to a low-carbon hydrogen economy.

5.09.P-We450 Variability of Organizational Carbon Footprint Depending on Accounting Standards and Data Sources: A Case Study
Anne de Bortoli[1], *Gael Plagnard*[1], *Cecile Sophie Marie Bulle*[2] *and Elliot Muller*[1], *(1)CIRAIG, Polytechnique Montreal, Canada, (2)UQAM, Canada*
Accurate organizational carbon footprinting is necessary to efficiently plan carbon neutrality of corporations. But different methodological choices are possible to conduct the calculations, in terms of accounting standards companies mostly use the GHG Protocol or the organizational LCA standard ISO/TS 14072 and emission factor sources - derived either from LCA, environmentally-extended input-output (EEIO) analysis, or a combination of both. The impact of the chosen accounting method and data on the estimated carbon footprint and its reliability, however, remains poorly understood. This study aims to illustrate these methodological choices influence estimated organizational carbon footprints on a case study.

We conduct 4 organizational carbon footprint assessments. We rely either on the ISO/TS 14072 standard or the GHG Protocol. We use different emission factors from ecoinvent (EI) v3.8, from OpenIO-Canada v2.0, or from the WRI resources provided online. The activity data used, provided by the company, include both economic and physical data. The physical data encompasses energy-related information and mass-based data (materials purchased). The economic data correspond to the physical inventories.

Results show that the organizational carbon footprint calculated vary by a factor of 4.6: 2350 tCO_2e for LCA combined to OpenIO-Canada, 5230 tCO_2e for the GHG Protocol with the WRI data, 10000 tCO_2e for the LCA combined to ecoinvent, and 10700 for the GHG Protocol combined to ecoinvent. Hotspots also vary depending on the accounting method, the most important contributor either being business travel (42%) for the LCA - OpenIO-Canada method, use of products (36%) for the GHG Protocol WRI method, and stainless steel purchases when using EI data.

Based on this case study, estimated organizational carbon footprints are highly dependent to accounting methodological choices especially the emission factors used. The use of EEIO emission factors for potential hotspot contributors is not recommended due to the high aggregation of the commodities represented in these databases. Nevertheless, EEIO data can usefully complete the assessment scope when

process-based data are not available, activity data are only provided in economic units, or resources to produce the accounting are very limited.

5.09.P-We451 Comparative Assessment of Environmental Performance: Green Roofs vs Conventional Roofs

Debora Pons Fiorentin[1]*, Sandra Rafael*[2] *and Paula Quinteiro*[1]*, (1)Centre for Environmental and Marine Studies (CESAM) & University of Aveiro, Portugal, (2)Institute of Environment and Development (IDAD), University of Aveiro, Portugal*

The growth of urban infrastructures and cities without sustainable planning has heightened vulnerability to extreme weather events, such as flooding and urban heat island effects. The building sector accounts for 37 % of global greenhouse gas emissions, and requires high energy consumption for heating and cooling, it has an important potential to implement sustainable strategies. The European Union has encouraged the synergy between green and gray infrastructures, emphasizing green roofs (GRs) as a key strategy to enhance urban resilience and improve buildings thermal performance. GRs, vegetated structures above buildings, can be classified into extensive and intensive types, based on their weight, type of vegetation, and maintenance needs. The Life Cycle Assessment (LCA) methodology has been applied to evaluate GRs environmental impacts. However, results diverge due to a lack of standardized technical guidelines. This study quantifies the environmental impacts of extensive and intensive GRs, designed according to expert-recommended technical guidelines, in comparison with a conventional flat roof (CR) in Portugal, applying the LCA methodology. The study also identifies the life cycle stage that most contributes to the roofs' total environmental impacts. Nine scenarios were developed: four extensive GRs, four intensive GRs, and one CR, varying the type and quantity of materials in the GRs substrate layer. The functional unit is 1 m2 of the roof with a lifespan of 40 years. All scenarios were assessed based on a cradle-to-grave approach including materials, construction, use and End-of-Life (EoL) stages. Overall, comparing GR with CR, CR presents the best environmental performance for all impact categories analysed, due to materials used in GR substrate. Comparing GR types, extensive GR has lower environmental impacts than intensive GRs, with reductions ranging from 34 % in Ozone formation - human health to 59 % in marine eutrophication, mainly attributed to the highest material needed for intensive GR. The hotspot analyses showed that the materials stage was the main contributor to the environmental impacts for the nine scenarios, except for the freshwater eutrophication and marine eutrophication impact categories, in which the EoL is the hotspot for the GR, due to the EoL of the substrate materials to a landfill. Future research should further explore the potential benefits of GRs, particularly how GRs affect the thermal performance of buildings.

Disclaimer/Disclosure: The authors would like to acknowledge the Portuguese Foundation for Science and Technology (FCT)/MCTES for the financial support to CESAM (UIDP/50017/2020+UIDB/50017/2020 + LA/P/0094/2020), through national funds. Paula Quinteiro also thanks to the research contract 2023.06946.CEECIND.

5.09.P-We452 Life Cycle Assessment of Reusable Bio-based Cups as a Substitute for Single-use Plastic at Festivals

Jan Puhar[1]*, Maria Troullou*[2]*, Polymnia Dagtzidou-Kisser*[2]*, Johannes Kisser*[2]*, Filip Miketa*[3]*, Leyre Hernandez*[4]*, Lidia Garcia*[4] *and Annamaria Vujanovic*[1]*, (1)University of Maribor, Slovenia, (2)Alchemia-nova Greece, Greece, (3)Bio-Mi, Croatia, (4)AITIIP Technology Centre, Spain*

Single-use plastic materials present a significant threat to the environment due to their contribution to resource depletion and plastic pollution. Fossil-based plastic products, which dominate the market, take an exceedingly long time to decompose [1]. The tourism industry stands out as a major contributor to the proliferation of single-use plastics, most notably typified by touristic sites experiencing a surge in plastic waste during peak seasons. Addressing this issue requires innovative and sustainable solutions that not only mitigate plastic waste but also promote a circular economy and zero-waste alternatives. The implementation of such measures is crucial for achieving sustainability, which encompasses environmental, economic, and social dimensions. To evaluate the effectiveness of these solutions, it is essential to quantify their impacts across all three pillars with holistic evaluation methods. The solution proposed in this study are reusable bio-based cups for beer consumption at festivals and other large-scale events, serving as a substitute for conventional single-use polypropylene cups. The analysis focuses on evaluating the environmental, economic, and social impacts of implementing this alternative on a large scale in comparison to a business-as-usual approach, using a case study of a widely visited music festival event site.

Disclaimer/Disclosure: The authors would like to acknowledge financial support from the European Commission for the project REMEDIES awarded under Grant Agreement No. 101093964.

5.09.P-We453 The EcoBeautyScore Association's Approach to Quantifying Data Representativeness of Cosmetic Product Formulas and Its Applications in Environmental Scoring Calibration and Future Data Development

*Sophie Achigar[1], Alessio Aufoujal[1], Tasnim Balgobin[1], Eric Bone[2], Andrea Carrao[3], **Laurent Gilbert**[2], Stephanie Johann[1], Mathilde Kolenda[1], Sacha Laruelle[4], Jacques L'Haridon[2], Camille Martin[2], Olena Onyshchenko[5], Anke Pilzner[6], Jennifer K. Saxe[7], Pascal Seel[6] and Jad Zoghaib[2], (1)EcoBeautyScore Association / Quantis, France, (2)EcoBeautyScore Association / L'Oreal Recherche & Innovation, France, (3)EcoBeautyScore Association / Kao USA Inc, United States, (4)EcoBeautyScore Association / LVMH Recherche Parfums & Cosmetiques, France, (5)EcoBeautyScore Association / Henkel AG & Co. KGaA., Germany, (6)EcoBeautyScore Association / Beiersdorf AG, Germany, (7)EcoBeautyScore Association / Kenvue, United States*

The EcoBeautyScore (EBS) Association*, comprising over 70 global cosmetic companies and associations, has developed a unified environmental footprint measurement and scoring system for cosmetic products over the past three years. This system is based on Life Cycle Assessment (LCA), recognized by the European Commission (EC) as the most effective method for assessing and comparing the environmental footprint of products and services. The LCA methodology aligns with the Product Environmental Footprint (PEF) guideline initiated by the EC in 2013. Moreover, the method was enhanced to suit the cosmetic specificities.

To ensure meaningful comparisons, products being compared must fulfil the same function. As such, we segmented products across over 30 basic services, such as hair washing and face moisturizing and treatment. In each segment, high product diversity dictated the need for a statistical approach to: (1) define a representative sample of products, leveraging product data from the large number of participating companies, and (2) calibrate an A to E scoring scale. Furthermore, cosmetic products include a broad array of diverse ingredients within each product segment. Gathering data for such a large number of ingredients is challenging, so we developed read-across and other approaches to avoid a no data, no impact situation, but this led to varied levels of data representativeness among ingredients.

The PEF initiative provides precise instructions for dealing with data collection and data quality. At this stage of EBS method development, strict adherence to these instructions was not achievable for the large ingredient portfolio in scope, and this will be addressed in the future. In the interim, and following the principles of PEF, we developed a numeric indicator to understand the representativeness of our ingredient data characterizing production and end-of-life impacts. For packaging, there is less material diversity and no pathway in the EBS method to score a product that lacks specific. Therefore the indicator characterizes ingredient data representativeness only.

This indicator was used to select the products to include when calibrating the A to E scoring scale, ensuring only inclusion of products with footprint values underpinned by a high proportion of representative data. This approach is key to ensure that meaningful consumer-facing scores are communicated and to prioritize future data development to improve representativeness.

Disclaimer/Disclosure: The EcoBeautyScore initiative started as a consortium in 2021 and turned into an association (under the Belgium Law) in 2024.

5.09.P-We454 Integrating Safe and Sustainable by Design (SSbD) Principles into the Battery Passport: Necessities and Benefits

*Jose Jorge Esp Gallart, David Sanchez Domene and **Laura Mayor Perez**, Eurecat, Centre Tecnol gic de Catalunya. Waste, Energy and Environmental Impact Unit, Spain*

The battery passport represents a transformative initiative for ensuring transparency and sustainability in the battery value chain. However, while numerous efforts have been made to establish this tool, integrating Safe and Sustainable by Design (SSbD) principles has yet to gain traction. This omission is partly due to the absence of legislative requirements. Nevertheless, the SSbD framework, with its holistic approach to safety, environmental, economic, and social dimensions, has the potential to enhance sustainability aspects critical to battery development usage, recycling and reuse. Its adoption could also promote broader dissemination and comprehension across the value chain.

To address this gap, work performed analyzed existing battery passport initiatives to identify the sustainability metrics they incorporate and pinpoint areas for improvement. Building on these insights, it is proposed specific indicators aligned with the SSbD framework that address current deficiencies. Approach developed is grounded in a prioritization and scoring system designed to quantify SSbD performance focused in areas covered by the battery passport. This system integrates, as a keystone, stakeholder perspectives, ensuring that the proposed metrics are both practical and aligned with the expectations of key actors in the battery ecosystem.

Although results from this case study are pending, preliminary findings suggest that the SSbD-based scoring system aligns well with legislative requirements such as the EU Battery Regulation and the proposed sustainability criteria for batteries. By addressing both current and anticipated regulatory frameworks, the SSbD framework and linked developed system offers a robust, forward-thinking solution for the integration of sustainability and safety considerations into the battery passport.

Hence, study has allowed to highlights the relevance of embedding SSbD principles into such emerging initiative. It underscores how these principles can bridge gaps in existing methodologies, foster value chain alignment, and enhance the overall safety and sustainability of battery technologies. Such advancements are crucial for enabling the transition to a more sustainable and secure energy future.

5.09.P-We455 Assessing the Environmental Footprint of the Dutch Healthcare Sector – A Hybrid Methodology

***Martijn van Bodegraven**, Tinia de Bruycker, Jannie Coenen and Susanne Waaijers-van der Loop, RIVM Dutch National Institute for Public Health and the Environment, Netherlands*

Within the global efforts towards a sustainable society, monitoring national footprints is a central tool to track sustainability targets. In the Netherlands, these targets have been set on a sectoral level to improve decision-making, since different economic sectors impact the environment in distinctive ways. In this line, the healthcare sector has committed to monitor its own environmental footprint to track its contribution towards climate, biodiversity and circular economy goals. A first calculation showing that healthcare is responsible for 7.3% of the national carbon footprint reflects the urgency for mitigation action within the sector.

While environmental footprints for healthcare sectors mostly result from input-output analyses (IOA), the Dutch healthcare sector s will be periodically calculated using a hybrid methodology combining the completeness of an IOA with the specificity and actuality of life cycle assessments (LCA) to the largest extend possible. In comparison to a classic IOA, this hybridization allows for a further specification of the results, whether between sub-sectors (e.g., hospitals, residential care,) or between products/services that are aggregated within IOA databases (e.g., medical appliances, pharmaceuticals,), making the results more actionable. It also allows for more actual data from healthcare institutions and related industries to be incorporated so that mitigation efforts can be better reflected in the results.

The hybrid methodology results from a review of the available multi-regional input-output (MRIO) databases and from a thorough inventory of the existing data sources within the Netherlands. It will be applied iteratively to respond to data needs for tracking environmental goals and fulfilling legal obligations applying to the sector (e.g., from the corporate sustainability reporting directive (CSRD)) while considering practical limitations, such as potential administrative burden linked to data collection. The first iteration will combine data from the PBL-FIGARO MRIO database, expenditure data from healthcare institutions and from consumption of medical products, as well as transport, energy usage, and water usage data collected within the sector, and waste production and management data collected nationally. The environmental impacts that will be calculated are greenhouse gas emissions, resource depletion, land use, water consumption, and waste production.

Disclaimer/Disclosure: Research within the 2023-2026 RIVM programme Sustainability & Health (Duurzaamheid en Gezondheid) financed by the Dutch Ministry of Health, Sports and Welfare (VWS).

5.09.P-We456 Regional Variability in the Carbon Footprint of Canadians: Insights from OpenIO-Canada

***Cecile Sophie Marie Bulle**[1], Laure Patouillard[2], Anne de Bortoli[1] and Maxime Agez[1], (1) Polytechnique Montreal, Canada, (2) Polytechnique & Universite du Quebec Montreal, Canada*

Decarbonization goals demand precise and regionally specific assessments of greenhouse gas (GHG) emissions to support effective climate mitigation policies. This study introduces OpenIO-Canada, a multi-regional environmentally extended input-output database with capital endogenization, developed to assess the consumption-based carbon footprint (CBCF) of Canadian provinces and territories (P&Ts) in 2019. Unlike traditional territorial-based assessments, CBCFs attribute emissions to final consumers, accounting for the production and transportation of goods and services across regions and internationally.

Our analysis highlights significant disparities among Canadian P&Ts. While the average Canadian emits 18 tCO?eq. per year, per capita CBCFs range from 14.5 tCO?eq. in Quebec to 38 tCO?eq. in the Northwest Territories, driven by differences in population density, consumption patterns, energy mix, and infrastructure needs. Housing, transport, and food collectively account for 69% of Canada s CBCF, with transport emissions dominated by direct vehicle use, housing emissions linked to energy consumption and construction, and food-related emissions stemming from agricultural production, particularly meat and dairy.

Notably, capital formation representing infrastructure and durable goods contributes 19% of the national CBCF, underscoring the importance of accounting for these emissions in climate strategies. Regional energy production methods significantly influence carbon intensity, with provinces like Alberta and Saskatchewan displaying higher footprints due to fossil fuel-based electricity, compared to provinces with cleaner energy mixes such as Quebec and British Columbia.

The findings offer actionable insights for stakeholders. Policymakers can leverage these results to prioritize decarbonization strategies tailored to regional contexts, focusing on reducing emissions in housing through energy efficiency, promoting sustainable transport, and shifting to lower-carbon diets. The integration of capital endogenization enhances the accuracy of CBCF assessments, emphasizing the need for sustainable infrastructure investments. OpenIO-Canada s detailed regionalization provides a robust foundation for advancing Canada s transition to net-zero emissions by 2050.

Disclaimer/Disclosure: This work is part of the Inclusive DIALOGUES towards an operational concept of energy citizenship to support the Energy Union project, and has been funded by the following grants: a) New Frontiers in Research Fund (NFRF) - Global from Social Sciences and Humanities Research Council of Canada (SSHRC) under the grant number NFRFG-2020-00448; b) support from Fonds de Recherche du Québec (FRQ) to the NFRF Horizon 2020 under the grant number 2022-FNFR-310334; c) PSO International program from Ministère de l Économie, de l Innovation et de l Énergie du Québec (MEI) under the grant number 21-22-PSOv2c-51973.

5.09.P-We457 Life Cycle Assessment of Crops in India

***Ambika Selvaraj**, Indian Institute of Technology, India*

In India, the agricultural sector is undergoing rapid modernization to meet the food demands of a growing population. However, this modernization has negative impacts on the ecosystem, human health, and resources due to the extensive use of agrochemicals and emission-intensive farming practices. It is therefore crucial to assess the sustainability of agriculture in India. This paper presents the first-ever impact assessment of the cultivation of 21 commonly grown crops in India, focusing on their production and emissions. The study identifies the crops with the highest impact on various parameters, such as rice, sugarcane, wheat, and banana. For instance, coconut cultivation is found to contribute significantly to global warming, while potato and sugarcane have a greater impact on water and ozone depletion, respectively. The study recommends improvements in farming practices to reduce emissions and promote sustainability. Additionally, the paper evaluates the connection between these 18 impact indices and the 17 sustainable development goals (SDGs) related to agriculture. This assessment helps identify the appropriate indices to measure agricultural sustainability and highlights areas for improvement or the need for new indices. By considering these findings, India can work towards achieving the SDGs while minimizing environmental impact and ensuring socio-economic aspects are not compromised in crop production and agricultural systems.

Disclaimer/Disclosure: Publication: Ambika S, Jagratti, Shikar, Gaurav, Sustainability Assessment of Crops in India, Current Research in Environmental Sustainability, https://doi.org/10.1016/j.crsust.2021.100074

5.09.P-We458 Packaging Choices and Their Role in Reducing Product Loss and CO2 Impact of Moisturizing Products: Insights for PEF Methodology and Sustainable Design

***Tasja Hafner-Kuhn**[1], Andrin Gstohl[1], Michelle Klein[2], Charlotte Neumair[1], Silvia Apprich[2] and Manfred Tacker[1], (1)Circular Analytics TK GmbH, Austria, (2)FH Campus Wien, Austria*

The primary function of packaging is to protect the packaged good, ensuring its integrity and usability throughout its lifecycle. Improper packaging can lead to product loss, increased environmental burdens, and economic inefficiencies.

A benchmarking study of 124 cosmetic products on the Austrian, German, and Swiss markets revealed that viscous products are prone to leave significant residues in packaging such as 26.65% for hand creams in pump dispensers resulting in considerable waste. Life cycle assessment (LCA) comparisons reveal that while packaging materials differ in environmental impact, the filling product typically has a significantly higher CO2 impact than its packaging. Thus, selecting the correct packaging is critical to minimise product loss and its associated environmental consequences.

This study focuses on climate change impacts of packaging formats and product loss due to incomplete emptiability. Other loss factors, such as incorrect storage or handling, are acknowledged but not included due to limited data availability. The research calculates the CO2 impacts of various moisturiser packaging formats across their lifecycle, including squeeze bottles, tubes, pump dispensers, jars, airless pump dispensers, and pouches. A single moisturising product formulation is used to standardise LCA comparisons. The LCA study uses the Circular Footprint Formula, as outlined in the Product Environmental Footprint method.

The study will test two hypotheses: (1) for viscous moisturising products, the CO2 impact of the product itself exceeds that of its packaging by at least 80% throughout its lifecycle, and (2) the ranking of CO2 impacts across packaging formats shifts when the CO2 impacts of moisturiser residue are included, as the total impacts (packaging + residue) alter the relative environmental performance of each format. These findings aim to advance sustainable packaging design by identifying residue thresholds that balance environmental and economic trade-offs.

By linking product loss to LCA outcomes, this research underscores the need for packaging designs that minimise residue, reducing both environmental and consumer costs. These findings also lay the groundwork for developing Product Environmental Footprint Category Rules, highlighting the role of packaging functionality such as product protection and emptiability often overlooked in traditional LCA comparisons.

5.09.P-We459 How much of the Smart Grid Have We Mapped? A Review of Their Environmental Coverage

Mikel Fadul Bonamusa[1]*, Gabriela Benveniste*[2]*, Victor Ferreira*[3]*, Isabella Bulfaro*[4]*, Anna Sanchez Ballesta*[3]*, Cristina Corchero Garcia*[3] *and Beatriz Amante Garcia*[5]*, (1)Leiden University, Spain, (2)University of Castilla-La Mancha (UCLM), Spain, (3)Energy Research Institute of Catalonia (IREC), Spain, (4)Energy System Analitics, Polytechnic University of Catalonia, Barcelona, Spain, (5)ENMA (Environmental Engineering), Universitat Politicnica de Catalunya (UPC), ESEIAAT (Escola Superior d Enginyeries Industrial Aeronautica i Audiovisual de Terrassa), Spain*

With the increasing electrification of different sectors, smart grids (SG) are considered a critical technology supporting decarbonization in our societies. SG involves a massive deployment of devices to gather and transport information and act upon the grid remotely or automatically. We want to know how much of this grid has been environmentally assessed, what needs to be done, and which claims have been made until now.

The assessment started with an exhaustive bibliometric review following the PRISMA methodology, combining a structured and non-structured literature search. We considered work that looks at infrastructure needs, conceptual frameworks, and visions of SG and its technologies, as well as environmental assessments.

Most of the reviewed work ensures that SG will bring energy and greenhouse gas (GHG) savings. This is justified through increasing energy efficiency, although some studies point out that rebound effects could jeopardize these savings. Studies have only considered the end of the distribution lines, considering smart meters and Home Energy Management Systems, leaving the whole transmission and most of the distribution lines unattended.

Due to SG's complexity, the type and quantity of devices used in the two grids will not be the same, making it impossible to determine a fixed set of devices to model SGs. Nevertheless, we believe there is an over-optimistic vision of SG based on a broad vision of the concept and a partial assessment. We hypothesize that deploying the infrastructure may entail emissions beyond GHG that energy savings might be unable to balance. Therefore, a broader perspective of the SG infrastructure should be captured, and further environmental analyses should be conducted on the distribution and transmission infrastructure.

Disclaimer/Disclosure: Acknowledgement - This study is framed under the Integrate project, which has received funding from the Ministry of Science and Innovation from the Spanish government, under the program "Proyectos de Generación de Conocimiento".

5.09.P-We460 Environmental Sustainability of Conventional and Electric Bicycles: A Review

*Paulino Duarte, **Debora Pons Fiorentin** and Paula Quinteiro, Centre for Environmental and Marine Studies (CESAM), University of Aveiro, Portugal*

In 2022, the transport sector accounted for 29 % of the European Union's (EU) greenhouse gas (GHG) emissions, making it one of the major sources of these emissions in EU. The EU's primary objective in combating climate change is to achieve carbon neutrality by 2050, positioning itself as the world's first carbon-neutral continent. Transitioning to low-emission transport modes has been identified as a key strategy to reach this target. Bicycles, particularly electric bicycles, have become increasingly popular as a strategy for reducing reliance on fossil-fuel-powered vehicles. The environmental impacts of bicycles, conventional and electric bicycles, have been evaluated with the Life Cycle Assessment (LCA) methodology. However, methodological choices and assumptions have led to different LCA results. This study conducts a systematic review of LCA-based research on the environmental performance of conventional and electric bicycles to identify and understand, in a quantitative analysis, how different methodological choices influence global warming (GW) results. The literature review has been conducted using electronic databases (Scopus and Web of Science) for LCA-based studies published in peer-reviewed journals. A final sample of 28 papers published in peer-reviewed journals, was reviewed, based on a thorough analysis of methodological choices, including functional unit, the system boundaries, and the most evaluated impact categories.
The results show that most case studies (89 %) applied a cradle-to-grave approach, while cradle-to-gate was considered in 7 % and cradle-to-user in 4 % of the case study papers. High variability was observed for GW, ranging from 0.0015 to 0.3150 kg CO2eq/pkm for conventional bicycles and 0.0160 to 0.1673 kg CO2eq/pkm for electric bicycles. The higher results for both bicycle types relate to the shared bicycle systems. The results show that conventional shared bicycles present higher GW impact values than shared electric bicycles, primarily due to the overall shorter lifespan distance of conventional bicycles compared to the longer lifespan distance of electric bicycles.
The EoL stage of electric bicycles still needs more detailed data. Future research should harmonise the methodological choices, and explore EoL waste treatment, especially for batteries (Lead-acid and Lithium).

Disclaimer/Disclosure: This study was funded by the PRR Plano de Recuperação e Resiliência and by the Next Generation EU funds at Universidade de Aveiro, through the scope of the Agenda for Business Innovation AM2R Agenda Mobilizadora para a inovação empresarial do setor das Duas Rodas (Project nº 15 with the application C 644866475 00000012). The authors would also like to acknowledge the Portuguese Foundation for Science and Technology (FCT)/MCTES for the financial support to CESAM (UIDP/50017/2020+UIDB/50017/2020 + LA/P/0094/2020), through national funds. Paula Quinteiro also thanks to the research contract 2023.06946.CEECIND.

5.09.P-We461 Providing a Science-Based and Harmonized Environmental Scoring Scheme for Cosmetics: The EcoBeautyScore

*Sophie Achigar[1], Alessio Aufoujal[1], Tasnim Balgobin[1], Eric Bone[2], Andrea Carrao[3], Iguatemi Melo Costa[4], **Laurent Gilbert**[2], Stephanie Johann[1], Mathilde Kolenda[1], Sacha Laruelle[5], Rebekah Lees[1], Jacques L'Haridon[2], Camille Martin[2], Olena Onyshchenko[6], Anke Pilzner[7], Jennifer K. Saxe[8], Pascal Seel[7], Harald Streicher[7], Laura Tasso[1] and Jad Zoghaib[2], (1)Quantis, France, (2)L'Oreal Research & Innovation, France, (3)Kao USA Inc., United States, (4)Natura Cosmeticos SA, Brazil, (5)LVMH Recherche Parfums & Cosmetiques, France, (6)Henkel AG & Co, Germany, (7)Beiersdorf AG, Germany, (8)Kenvue, United States*

The EcoBeautyScore (EBS) Association*, comprising over 70 global cosmetic companies and professional associations, has developed a unified environmental footprint measurement and scoring system for cosmetic products over the past three years. This system is based on Life Cycle Assessment (LCA), recognized by the European Commission (EC) as the most effective method for assessing and comparing the environmental footprint of products and services. The LCA methodology builds on the

Product Environmental Footprint (PEF) guideline initiated by the EC in 2013. Moreover, the method was enhanced to suit the specificities of cosmetics. This communication is dedicated to presenting the overall EBS footprint and scoring methodology.
The EBS footprint methodology aligns with the key PEF principles, assessing 16 midpoint impact categories across a full cosmetic product s lifecycle. Products are evaluated based on the same functional unit, using a data hierarchy to derive usage doses for cosmetic technologies. Moreover, to address limitations concerning robustness and data coverage in the PEF-prescribed USEtox 2.1 model for freshwater ecotoxicity, an adapted method was implemented using the Most Sensitive Species-HC5 (hazardous concentration for 5% of species) approach.
A common database for production and end-of-life impacts of standard raw materials was created, prioritizing prevalent and impactful ones, complemented by a comprehensive data strategy. Significant enhancements in data coverage and quality for the end-of-life ecotoxicity freshwater database were achieved by developing new characterization factors. Additionally, incorrect and obsolete factors were replaced to enhance applicability of the USEtox model for cosmetics.
To make PEF outcomes clear to consumers, a product segmentation approach is used, comparing only products with the same primary cosmetic benefit. A portfolio assessment combined with a representative sampling defines environmental performance classes from A to E per segment.
Tested on over 1,900 products, results show that for rinsed-off products like Hair Wash, the use phase is a major PEF contributor, followed by ingredient production and end-of-life. For Face Care products, ingredients are also a significant contributor, but they show no use phase impacts, and packaging production has a more significant impact.

* The EcoBeautyScore initiative started as a consortium in 2021 and turned into an association (under the Belgium Law) in 2024.

5.09.P-We462 Using LCA to Support Decision-Making in Water Management: Conventional vs. Desalination Strategies in Sicily

Edoardo Teresi[1]*, Letizia Caroscio*[1]*, Gabriele Freni*[2]*, Cristian Chiavetta*[3] *and Alessandra Bonoli*[1]*, (1)University of Bologna, Italy, (2) Università degli Studi di Enna "Kore", Italy, (3)ENEA - Italian National Agency for New Technologies, Italy*

The Life Cycle Assessment (LCA) framework has become an important tool for quantifying environmental sustainability and guiding decision-making in policy and industry. This study applies LCA to evaluate water management strategies in Sicily, Italy, a region severely affected by climate change and water scarcity.
Rising global temperatures and extreme weather events have drastically reduced water availability, with national water resources declining by 20% during 1991-2020 compared to the 1921-1950 average. With its aging infrastructure and significant resource losses (45% in distribution networks), Sicily is among the most impacted regions.
This research focuses on comparing the environmental performances of three water production methods: conventional sources, seawater desalination, and brackish water desalination from central Sicilian aquifers.
Groundwater, currently supplying 42% of distributed water, has been overexploited, leading to critical aquifer depletion and chemical contamination.
Desalination, though underutilized in Italy, offers a promising alternative. However, its adoption faces barriers such as limited R&D investment, high energy demand, and complex permitting processes. Comparatively, countries like Spain have successfully integrated desalination into resilient and diversified water systems.
Recent legislative measures, such as the Italian Drought Decree (Decree-Law No. 39 of April 14, 2023), aim to streamline the development of small desalination plants (<50,000 m^3/day), but comprehensive feasibility studies are still required to assess their environmental and economic viability.
The LCA framework in this study is designed to quantify the environmental impacts of these methods and support policymakers. Particular attention is given to methodological choices, such as system boundaries and impact categories, to ensure robust and actionable results.
Situated in a water-stressed region, this research highlights the importance of integrating innovative water technologies into sustainable and resilient management strategies, aiming to bridge the gap between environmental analysis and practical implementation.

5.09.P-We463 Enhancing Environmental Impact Assessment: A Multi-Lens Approach to Sustainable Product Design for Cosmetics & Personal Care Products

Eleanor Kirwan[1]*, Lucas Piquini*[2]*, Oliver Price*[1]*,* ***Jennifer K. Saxe***[2] *and Catherine Smith*[2]*, (1)Kenvue,*

Switzerland, (2)Kenvue, United States
In the Cosmetics and Personal Care sectors, higher environmental impacts typically occur during the production of raw materials used to create formulations and packaging, and their impact after consumer disposal. To reduce the environmental impact of such products, integrating sustainability into the product design process is therefore becoming increasingly important. The development of sustainable design tools, built on scientific principles is key to guide product development teams.

Life Cycle Assessment (LCA) is often considered the gold standard for measuring product environmental impact, but it is only one lens to measure sustainability through and has limitations for certain product types. An assessment of product environmental impact can be strengthened by combining LCA with additional methodologies that highlight other important factors (e.g., unforeseen persistence-related impacts of ingredients and materials). Leveraging a multi-lens approach can create a decision-making framework which prevents product developers from making unintended tradeoffs when designing for sustainability.

The Sustainable Innovation Profiler (SIP) is a patent pending, sustainable design tool that enables product developers to compare a new product s environmental impact with that of a baseline during the prototyping process and assess the holistic environmental impact of products in the Cosmetics and Personal Care sectors. The SIP tool includes three separate methodologies. The first is an LCA-based method inspired by the European Commission s Product Environmental Footprint (PEF) method, assessing a product s cradle to grave environmental impact across 16 key indicators. A second method evaluates the environmental impact of the product s formulation through a different lens. This method has the peer reviewed and patented Global Aquatic Ingredient Assessment (GAIA) at its core with scoring modifications for: (1) ingredients with potential emerging concerns and (2) ingredients sourced from a renewable origin. Finally, a third method measures the sustainability of the product s packaging using a framework which emphasizes the importance of designing packaging for recyclability, increasing the use of recycled materials and using materials efficiently.

This poster introduces the tool and its holistic approach to assessing product environmental impact and features a case study on the application of this framework for a product from the Cosmetics and Personal Care sector.

5.09.P-We464 Enhancing Sustainability in Biotechnology: A Comparative Life Cycle Assessment of Single-Use Assemblies

***Winfried Bulach**[1], Karoline Wowra[1], Marisa Maher[2], Athanasios Gkrillas[3], Lidia Ceriani[4] and Florian Gruener[1], (1)Merck Life Science KGaA, Germany, (2)MilliporeSigma, United States, (3)Merck Life Science BV, Belgium, (4)Merck Life Science Srl, Italy*
The Life Science business of Merck KGaA, Darmstadt, Germany, offers a diverse portfolio of over 300,000 products essential for research and development in biotechnology and pharmaceuticals. In July 2023, we implemented a portfolio sustainability assessment (PSA) approach, based on the World Business Council for Sustainable Development (WBCSD) standards, to facilitate our sustainable portfolio transformation. This initiative integrates hazard screening, regulatory trends, and sustainability performance, aligning with the Safe and Sustainable by Design (SSbD) framework. The inherent complexity of Merck s chemical portfolio poses challenges in comprehensively applying ISO-compliant Life Cycle Assessment (LCA), necessitating a practical approach for communicating results to non-experts and for reporting on environmental sustainability.
In this study, we conducted a comparative LCA of two single-use assemblies, each utilizing different films. One assembly features an improved film with enhanced bag strength, improved durability, and leak resistance through a novel strength layer reinforced by woven nylon. The study adhered to ISO 14040/44 standards using the EF method 3.1. An independent critical review ensured compliance with these standards, reinforcing the study's reliability and trustworthiness. For this, we engaged experts for the critical review panel, ensuring comprehensive coverage of necessary expertise. Challenges primarily arose in data collection due to the novelty of the process and significant data gaps from incomplete supplier information. To address these, we employed AI tools to fill data gaps for mass flows and energy demands. The motivation behind this extensive effort was to produce a credible and trustworthy study that fosters customer confidence by demonstrating the environmental performance of the novel and improved film for challenging single-use applications. This contribution discusses the challenges encountered in designing and executing the LCA, particularly in terms of methodology, data management, and communication of results to non-experts. It underscores the critical role of LCAs in decision support and reporting, highlighting the need for standardization and harmonization across sectors to enhance comparability and

effectiveness. Our findings contribute to the ongoing dialogue around the strengths and limitations of LCA frameworks, identifying future needs for methodological advancements in the Life Science sector.

5.09.P-We465 Quantification of Potential Impacts in the End-of-Life Phase of Construction Products in the EPD

Tatiana Trecakova *and Vladimir Koci, University of Chemistry and Technology Prague (UTC), Czech Republic*

EPDs (Environmental Product Declarations) are becoming a crucial tool in corporate sustainability and the entire supply chain. EPDs for construction products are prepared in accordance with EN 15804:2012+A2:2019+AC:2021 and the PCR for construction products, issued by EPD system operators. The aim of the Product Category Rules (PCR) is to provide verifiable and consistent data for LCA-based EPDs.

Construction products must declare modules A1-A3 (production phases), C1-C4 (end-of-life phases), and D (benefits and loads beyond the system boundary). Neither the PCR nor the standard provides specific requirements for phases C1-C4, which may lead to different approaches in quantifying potential environmental impacts. For phases C1-C4, which concern the end-of-life stage, it is required to consider impacts in a defined scenario.

In this study, different approaches for defining the scenario for phases C1-C4 are discussed. These approaches may depend on the region where the product will reach its end-of-life, the availability of data on different treatment options (by region, by time), and assumptions regarding consumer behavior, etc. The different approaches for the C1-C4 phases have been applied, analyzed, and evaluated, and the weak points have been identified using the example of a selected construction product.

A more accurate quantification of environmental impacts in the end-of-life phases would facilitate higher transparency in decision-making mechanisms and the enforcement of a circular economy.

5.09.P-We466 Organizational Climate Impact Accounting - Accounting for Actions That Matter: Supporting Sustainable Consumption of Buildings

Timen M. Boeve*, Soren Lokke and Jannick Schmidt, Aalborg University, Denmark*

This study proposes a new framework for carbon accounting, referred to as climate impact accounting. This new framework is focused on providing evidence-based decision support to reach current climate targets. Therefore, the study mainly focuses on cause-effect relationships, which ensures avoiding burden-shifting from one organisation to another and to avoid suboptimal decision that introduces additional GHG emissions at other points, in a system wide perspective. The study aims to account for potential impacts rather than to account for the share of global burdens belonging to the organisation as to provide better evidence-based decision support for a decicion. Consequential modelling (cLCA) is used as the underlying methodology for this study as it is acknowledged to provide optimal decision support through its use of marginal suppliers among other elemenets. The framework is applied to the organisation; Aalborg University to evaluate it and its functionally and applicability, and is based on an extensive consensus project for organisational footprints supported by Danish Universities (DKUNI). The paper therefore also present important improvements to current carbon accouting guidelines such as the GHG Portocol (GHGP) and ISO standards on LCA. The strenght of the approach is exemplified by adressing how to apply improved impact accounting of the use of buildings. The GHGP argues that emissions from buildings should only be accounted for once construction is completed. Therefore, if a building undergoes no maintenance and consumes no heating or electricity in a given year, it would be considered climate neutral. However, the proposed climate impact accounting method suggests that there is still an impact associated with the occupation of buildings. Occupying a building effectively removes it from the available market, which will drive an increase in the construction of new buildings from a system-wide perspective. Conversely, reducing the building stock at AAU would free up more space on the market, thus displacing the need for new construction. As a result, even a building built many years ago and with no maintenance or operational activity still has a climate impact as long as it remains occupied. This concept is similar to the principle applied to indirect land-use change (iLUC) in EXIOBASE.

5.09.P-We467 Life-Cycle Based Assessment of Green Laboratory Practices – A Case Study From an Austrian Institution of Higher Education

Bernhard Bichler, Klaudia Jarosz, Clemens Matteo osterle, Noah Weidner and ***Ursula Gabriele Knaack****, University of Applied Sciences Technikum Wien, Austria*

Recently, scientists have started developing an increasing awareness of the contribution of scientific practices to the global environmental crisis. Across disciplines grassroots movements are emerging, which promote improvements of the environmental footprint of scientific activities.

In institutions of higher education (IHE), experimental laboratories for chemistry and life sciences, so-

called wet labs, usually have particularly high unwanted environmental impacts. Therefore, a growing body of publications, programs and frameworks is promoting so-called green practices for these laboratories. Recommendations for such practices are very diverse, including e.g. guidelines for the handling of energy-consuming equipment like fume hoods and cold storage devices, establishment of green procurement, as well as training of researchers and students to foster waste prevention and separation. Efforts to establish green laboratory practices, however, often face severe resistance from laboratory staff and management alike, as some of them require behavioral changes and significant organizational efforts to implement.
One way of addressing such objections is data-based communication of environmental impacts and the potential of green lab practices to improve these impacts. Thorough assessment of individual practices also allows prioritization of measures with high environmental benefits. Thus, informed decision-making and effective improvement of environmental impacts is enabled within institutions.
We present data from a case study conducted at the chemistry and life science laboratories of the UAS Technikum Wien, an IHE in Austria. Based on on-site waste analyses and electricity measurements, selected green laboratory practices promoted in literature and by green lab initiatives are evaluated. Life cycle assessment is used to evaluate the environmental benefits of reduced use of consumables, as well as collection and separation of single-use bulk plastics for recycling. Moreover, reduction potential of the laboratories electricity demand is assessed.
By quantifying the potential impacts of green laboratory practices, the presented work contributes to data-based discussion and decision-making within the UAS Technikum Wien. Thus, implementation of such practices can be promoted more effectively.

Disclaimer/Disclosure: Financial support by the City of Vienna, MA 23 Project 32 09 is gratefully acknowledged.

5.10 Life Cycle Assessment of Waste and Waste Management Systems for Safe and Sustainable Futures

5.10.T-01 A Global Life Cycle Inventory Model for Urban Wastewater Treatment and Sanitation

***Ivan Muñoz**, 2.-0 LCA consultants, Spain*

We present WW LCI v5, a life cycle inventory (LCI) model developed during the last 10 years by 2.-0 LCA consultants. WW LCI covers the entire supply chain for wastewater management, namely wastewater collection and direct discharges, centralized wastewater treatment with different plant configurations and treatment levels, sludge treatment with and without anaerobic digestion and cogeneration with biogas, and sludge disposal (composting, agriculture, controlled/uncontrolled landfil, incineration), as well as wastewater reuse in agriculture. The model requires the user to define the composition of the wastewater discharge. This can be done at two levels or tiers: tier 1 where the user only knows some generic descriptors, such as chemical oxygen demand, while in the more advanced tier 2 the user can identify specific chemicals present in the wastewater (e.g. ethanol, sodium chloride).
The model is highly parameterized with more than 200 parameters. Also, a key feature is the country database, containing statistics on wastewater collection, treatment levels, sludge treatment and disposal, climate (temperatures, rainfall) for 101 countries and 2 regions (EU, GLO). A drop-down menu allows the user to automatically load a country scenario, thus accounting for geographical differences with just one click.
The model is programmed in Excel and links to the ecoinvent database. LCIs obtained by the user can then be easily exported to both SimaPro and Gabi software, in order to conduct impact assessment calculations.
We will show examples of using the model for different wastewater compositions in different geographies, the differences between tier 1 and tier 2 modelling, the importance of methane emissions in this area and of accounting for credits associated to the recovery of materials and energy.
WW LCI is the successful story of a crowdfunded project with a current community of 29 users, which are allowed access through a one-off fee. This allows 2.-0 LCA consultants to cover maintenance and further development costs. The model still has limitations, such as countries not yet covered, and the focus on urban wastewater, which limits to some extent its use to model industrial wastewater treatment. Yet, to our knowledge it is the most versatile and complete model for LCA practitioners willing to go a step further in addressing the life cycle impacts of wastewater discharges.

5.10.T-02 Reducing the Climate Impact of Residual Waste Treatment: A Comparative LCA of Carbon Management Strategies in a German Context

Sarah Schmidt *and David Laner, University of Kassel, Germany*
Achieving climate neutrality targets necessitates the evolution of MSW management concepts and treatment technologies. The retrofitting of MSWI with carbon capture and storage (MSWI_CCS) technologies and the recovery of materials from residual waste in material recovery facilities (MRF) are discussed as key carbon management strategies in MSW management in Europe. Identifying the long-term environmentally optimal waste management concept is crucial, as decisions in waste management often concern waste technologies with related infrastructure operating for 30 years or more. However, the evaluation of long-term waste management concepts is challenged by anticipated societal transformations over the next decades. Using the city of Kassel (Germany) as a case study, we perform a life cycle assessment to evaluate and compare MRF and MSWI_CCS as strategies for the reduction of GHG emissions associated with residual waste management. Sensitivity scenarios are employed to examine the impact of varying constraints, considering changes in waste inputs, material and energy systems, and substitution choices. Moreover, uncertainty analysis is applied to quantify the variability of GHG emissions linked to residual waste treatment resulting from parameter uncertainty.
The analysis revealed that residual waste treatment in Kassel in 2022 resulted in the direct emission of 857 kg CO2 per Mg of wet residual waste, with approximately 31% fossil CO2. Considering environmental savings linked to the recovery of energy and materials net GHG savings of 141 kg CO2-eq. per Mg wet residual waste were achieved. Carbon management strategies show potential to reduce direct fossil CO2 emissions by 27% (MRF) or 90% (MSWI_CCS) and to increase the net GHG savings of residual waste management by factor 1.6 (MRF) or 2.6 (MSWI_CCS). The comparative performance of MRF strongly depends on waste compositions, being preferable against MSWI_CCS for a residual waste with a high recyclables content. Overall, S_MSWI_CCS exhibits the highest potential for GHG reduction, outperforming S_MRF and S_MSWI under various conditions because of its resilience against variations in waste composition, energy and material systems, and substitution choices. In addition to offering practical guidance for residual waste management, this study underlines the importance of future-oriented decision-making in residual waste management and highlights the need for further research in prospective waste system modelling.

5.10.T-03 Modelling Metals Recycling With a Dynamic Lca Approach: A Methodological Discussion Based on a Real-World Case Study

Federico Rossi[1]*, Francesca Albano*[2]*, Marco Frey*[2]*, Fabio Iraldo*[2] *and Monia Niero*[2]*, (1)Sant'Anna School of Advanced Studies, Italy*
This study explores methodological approaches for modeling metals recycling using a Life Cycle Assessment (LCA) approach, drawing insights from both the ALCHIMIA and GRINS projects. The ALCHIMIA project focuses on the steel industry and utilizes a dynamic LCA approach that evaluates the environmental impacts of steelmaking using scrap materials. This study aims to provide a detailed comparison of three methods for modelling recycling in LCA: cut-off, system expansion, and the Circular Footprint Formula (CFF). These methods differ in how they allocate environmental burdens to recycled materials. In the cut-off method, recyclable materials are considered burden-free, with only the impacts from the recycling process, including energy, virgin materials, and transportations. The system expansion approach, also known as the substitution or avoided burden method, allocates a share of the previous lifecycle impacts of the material to the recycled product and subtracts the impacts from avoided production of primary materials. The CFF serves as an intermediate approach, providing a more balanced allocation of environmental burdens. The study employs a heat-by-heat dynamic LCA approach, in which Life Cycle Inventory (LCI) data vary depending on the specific steel product being produced and the composition of the scrap inputs, offering a granular understanding of recycling impacts in the steel industry. Data from a real-world steel plant were collected and modeled using all three approaches across eight steel families. Results showed that the cut-off approach, while providing less variable result, is more suitable for general benchmarking and baseline evaluations. On the other hand, the system expansion approach is better for understanding the impacts of specific products or the dynamic nature of the scrap mix. The CFF approach offers a flexible middle ground between the two, allowing for a trade-off between the advantages and disadvantages of the cut-off and system expansion methods. These findings are expected to guide future LCA studies, particularly in the context of the GRINS project, which applies similar methodologies to the aluminum sector. Further research could extend these insights to other recycling processes in the metal industry, enhancing the understanding of environmental impacts and supporting the decision making process.

5.10.T-04 Does Machine Learning Pay Off in Terms of Environmental Impacts? Insights from the Waste Management Sector

Julian Baehr[1]*, Tabea Hagedorn*[1]*, Anton Jager*[1]*, Phillipp Hamm*[2]*, Johannes Emmert*[2]*, Leonie Wenzel*[3]*,*

David Fahz[3], Johannes Laier[4], Liselotte Schebek[1] and Alice Precci do Carmo Lopes[1], (1) Technische Universitat Darmstadt, Germany, (2)Fraunhofer Institute for Integrated Circuits (IIS), Germany, (3)Fraunhofer-Einrichtung fur Wertstoffkreislaufe und Ressourcenstrategie IWKS, Germany, (4)WeSort.AI GmbH, Germany
The European Commission s Circular Economy Action Plan (CEAP) established the circular economy as a key element to achieve the European Green Deal s 2050 net-zero emissions target. For effective recycling, the waste management sector must adopt efficient waste collection, transportation, and sorting methods. The increasing volume and diversity of materials in waste streams, coupled with demands for low-emission secondary resources, call for new and innovative approaches. Artificial intelligence (AI), particularly machine learning (ML), offers promising solutions for optimizing these processes, such as improving waste sorting with advanced pattern recognition. However, it is essential to assess whether the environmental benefits of ML outweigh its potential impacts, particularly its energy consumption. Recent research highlighted the need to evaluate AI s environmental effects holistically, not just focusing on operational energy use but also considering the other impacts, using Life Cycle Assessment (LCA) methodology. Therefore, our study applied LCA to determine if ML s process efficiencies yield net environmental benefits within waste management. The study assessed four use cases in the plastics recycling chain, covering collection and sorting processes of plastic packaging waste.
The study s objectives were threefold: (i) to compile primary datasets on waste management activities through industry collaboration, addressing data gaps that are often filled with generic data; (ii) to assess the environmental impact of four ML technologies using LCA methodology; and (iii) to evaluate the net environmental benefit (or burden) of implementing ML in waste management.
Four use cases were analyzed: intelligent route optimization for waste collection (Use Case 1), inventory optimization to reduce empty trips (Use Case 2), and two additional ML applications for improving sorting efficiency. The LCAs followed ISO 14040/14044 methodology, with a consistent functional unit of treating one ton of post-consumer plastic waste and considered global warming potential, energy demand, and resource depletion impacts. The study results provide valuable primary datasets and offer novel insights into the environmental trade-offs of AI applications in waste management.

5.10.P-We468 Bayesian Belief Networks As a Tool to Inform on Plastic Clean-Up Technologies Net Benefits

*Giulia Leone[1], **Ana I Catarino**[2], Ine Pauwels[3], Marie Anne Eurie Forio[4], Gert Everaert[2] and Peter L.M. Goethals[4], (1)Ghent University; Flanders Marine Institute, (VLIZ); Research Institute for Nature and Forest (INBO); Research Foundation Flanders (FWO), Belgium, (2)Flanders Marine Institute (VLIZ), Belgium, (3)Research Institute for Nature and Forest (INBO), Belgium, (4)Ghent University, Belgium*
To collect and remove legacy plastic, which accumulates in the environment, new technological interventions are being deployed. These so-called plastic clean-up technologies can be installed in inland waterways, such as rivers and estuaries, where they can avoid the further spread of plastic to marine environments. There is however a lack of standardization in reporting plastic removal and unwanted biological bycatch since empirical data is scarce. The goal of this work was to develop, train, and validate Bayesian Belief Networks for plastic clean-up technologies. We propose to use these probabilistic models as a tool to assess the proportion of plastic and biota collection and removal by different clean-up mechanisms. The models can support stakeholders in deploying a clean-up technology by providing the proportion of plastic and biota collected depending on the technology, plastic pollution, and environmental conditions. To train, test, and validate the models, we used a set of experimental data collected in a current flume system run under controlled conditions. To develop the models, we have identified six variables in relation to three key aspects based on their ability to determine plastic removal and the biological bycatch. The type of clean-up mechanisms used (an air bubble curtain, two floating booms with a wheel) is a first key aspect. The intrinsic characteristics of the plastic and biota items (e.g., size, shape) as well as the number of items present have been identified as a second important set of key aspects. Finally, the hydraulic condition (flow velocity) of the waterway in which a mechanism is deployed is also incorporated. Based on the model with the highest technical reliability, simulations will be made to provide relevant scenarios and to evaluate the effect of the variables (e.g., flow velocity) on plastic and biota collection and removal.

Disclaimer/Disclosure: From the 1st of November 2021 Giulia Leone is supported by the Research Foundation Flanders (FWO), as a PhD grant strategic basic research, application number 1S13522N/1S13524N.

5.10.P-We480 Safe and Sustainable Recycling of Solar Panels: A Scenario Study

***Johannes Lijzen**[1], Frieke Heens[1], Martijn van Bodegraven[1] and Erik Dekker[2], (1)National Institute of Public Health and the Environment (RIVM), Netherlands, (2)Province Gelderland, Netherlands*

To assess and stimulate safe and sustainable recycling the National Institute of Public Health and the Environment (RIVM) developed a screening methodology to assess the circularity, environmental impact and safety of recycling of waste flows. This method was applied on the case of recycling of End-of-Life solar panels. It is expected that the first generation of solar panels will start to be taken out of use in large numbers in five years time. Various technologies to recycle solar panels are being developed.

The aim of this study was to investigate which recycling options appear to be feasible, how environmentally friendly they are and to learn how the screening methodology can help to make a comparison. We compared four future scenario s to the current situation (the baseline), in which no raw materials from End-of-Life solar panels are recovered, but are shredded and processed for a low-grade applications like road foundation. Three screening modules were applied for quantifying the circularity, environmental impact and the safety due to the presence or emission of substances of concern (SoC). Our analysis shows that all future options are more circular and have a lower environmental impact than the baseline. One scenario scores best on climate change (CO2-eq.), but all are much lower than the baseline. One of reasons is that it costs more energy to process new raw materials into solar panels than to use recycled raw materials. The option in which glass is recycled into new solar panel glass and the silicon can be recycled to high grade silicon, has also the highest value for the circularity indicator 'efficiency'. In the recycling process, attention should be paid to hazardous substances in solar panels: lead, antimony and per- and polyfluoroalkyl substances (PFAS). Lead is contained in soldering materials and antimony is added to make the glass brighter. The backsheets contain fluoropolymers, as a result of which PFAS can be released when they are incinerated. This can lead to human and environmental exposure, depending on how substances are released.

Based on this study we advised the national government to stimulate specific technological developments that enable high-grade recycling of solar panels. We also recommend to stimulate design for recycling. For example developing other encapsulant materials between the glass and the backsheet enables easier dismantling. It is also important to minimise the use of hazardous substances lead and PFAS.

5.10.P-We481 Bottom-Up, Dynamic Probabilistic Material Flow Analysis of Japanese Plastic Flows as an Initial Step to Understand the Chemical Additives Flows and Stocks

***Yiwen Zhang**[1], Zhanyun Wang[1], Masahiro Oguchi[2], Haruhisa Yamamoto[2] and Bernd Nowack[1], (1)Empa - Swiss Federal Laboratories for Materials Science and Technology, Switzerland, (2)National Institute for Environmental Studies, Japan*

The global production of secondary plastics has increased more than tenfold in the past two decades, creating a strong backflow from end-of-life (EoL) products to manufacturing. Secondary materials can substitute pristine resins in manufacturing, and therefore mitigate many of the related environmental impacts. However, the associated risks of secondary materials, particularly from the additives that persist through recycling processes, are not yet fully understood. Tracking the flows of chemicals in secondary materials requires high-resolution data on plastic flows. As a first step of achieving so, this study presents a dynamic probabilistic material flow analysis of plastic flows, with high granularity at the EoL stage. Japan was selected as a case study, due to the availability of comprehensive data. We compiled the production, trade, and consumption data for eight major types of commercial polymers for the period from 1950 to 2023. The amounts were allocated to 48 product categories following a bottom-up approach based on the annual sales data and the polymer composition of these products. Using the consumption data and lifetime distributions, we estimated waste generation for individual product categories. Twenty-three collection pathways were differentiated across general waste collection, industrial waste collection and sorted collection for specific product categories that are regulated under existing waste laws and/or managed by various industrial associations. The inputs and outputs of mechanical recycling were modeled accordingly. Our results show a significant increase in recycling activity following the establishment of respective recycling laws. However, the absolute quantities of secondary plastics remain relatively low compared to those that were sent to energy recovery and landfill. Secondary materials primarily originate from containers and packaging, electronics, and motor vehicles. These findings provide initial insights into the types of secondary polymers and chemicals likely present therein, forming a basis for future quantification of the flows of chemical additives and their environmental and human health impacts.

5.10.P Life Cycle Assessment of Waste and Waste Management Systems for Safe and Sustainable Futures

5.10.P-We468 Bayesian Belief Networks as a tool to inform on plastic clean-up technologies net benefits

*Giulia Leone[1], **Ana I Catarino**[2], Ine Pauwels[3], Marie Anne Eurie Forio[4], Gert Everaert[2] and Peter L.M. Goethals[4], (1)Ghent University; Flanders Marine Institute, (VLIZ); Research Institute for Nature and Forest (INBO); Research Foundation Flanders (FWO), Belgium, (2)Flanders Marine Institute (VLIZ), Belgium, (3)Research Institute for Nature and Forest (INBO), Belgium, (4)Ghent University, Belgium*

5.10.P-We469 Enhancing Environmental Sustainability through Industrial Symbiosis in Plastic Waste Recycling

*Christine El Khoury[1], Ana Somoza-Tornos[2], **Carlos Pozo**[1] and Laureano Jimenez[1], (1)Universitat Rovira i Virgili, Spain, (2)Delft University of Technology (TU Delft), Netherlands*

Plastics, primarily derived from fossil-based feedstocks, face significant end-of-life (EOL) challenges, with a large volume of plastic waste being diverted to linear options such as landfill, incinerators and the environment. European Green Deal s objective for circularity and climate neutrality aims at combining mechanical and chemical recycling, by employing circular economy principles of retaining resources at their highest possible value. This strategy creates a path towards a more sustainable manner for managing plastic waste. This study investigates the environmental benefits of integrating mechanical and chemical recycling methods within a circular economy framework. Two common plastics, low-density polyethylene (LDPE) and polypropylene (PP), were analyzed, using input-output data gathered from the literature, across various EOL scenarios. Life Cycle Assessment (LCA) using SimaPro was applied to analyze the environmental impacts of the two supply chains independently, from monomer production to EOL, across four scenarios: mechanical recycling with incineration or landfill, mechanical and chemical recycling, and the fourth being a replica of the third with the incorporation of industrial symbiosis between the two supply chains.

Largest environmental impacts from human health and ecosystem were witnessed in the scenario that combined mechanical recycling and incineration. Processing of the polymer accounted for the largest share in each process (for human health 34-46% for PP waste, 32-43% for LDPE waste, and for ecosystems 26-39% for PP waste and 37-51% for LDPE waste). Pyrolysis products led to avoided impacts of 14% for propylene from wPP and 9% for ethylene from wLDPE, due to the reduced virgin feedstock reliance. Industrial symbiosis achieved the lowest impacts in all the impact categories chosen, leveraging waste pyrolysis and material exchange to minimize resource extraction and environmental burdens. Integrating industrial symbiosis with mechanical and chemical recycling maximizes environmental benefits by reducing resource impacts and dependence on virgin materials, highlighting its potential for enhancing circularity in plastic waste management. This framework can guide policymakers and industries toward sustainable plastic waste management strategies.

5.10.P-We470 Using Life Cycle Assessment to Evaluate the Potential for Compostable Plastics

***Maryam Hoseini**, Stuart Walker and Rachael Rothman, University of Sheffield, United Kingdom*

Growing concern regarding the accumulation and management of traditional plastics waste has promoted interest in bio-based and biodegradable plastics due to their promising end-of-life i.e. biodegradation. However, to ascertain the sustainability of biodegradable plastic and enable consumers and producers to identify more sustainable methods of use, production, and disposal for such products, measurement of their environmental impacts is important. The application of comprehensive Life Cycle Assessments (LCA) studies are imperative to carefully evaluate sustainability of bio-based and biodegradable plastics. However, many life cycle assessments of these plastics do not considered the EOL phase due to a lack of consistent data, even though this stage can strongly affect the conclusions. Therefore, the goal of this study was to analyse published LCA studies on biodegradable plastics, focusing particularly on compostable plastic and the way end of life of the plastics are modelled i.e. composting. Gaps in current data are highlighted along with improvements needed to give an accurate environmental picture of compostable plastics. The results show that there is no general approach to model composting processes. There is a lack of data on timing of CO2 emission, consequences of applying compost on soil and specific material degradation rate.

5.10.P-We471 Environmental and Economical Assessment of Enzymatic Depolymerization for Polyethylene Terephthalate (PET) Waste

***Ashkan Nabavi-Pelesaraei** and Anders Damgaard, Technical University of Denmark, Denmark*

Traditional recycling of polyethylene terephthalate (PET) through mechanical processes has limitations. Specifically, low-purity PET waste is often diverted to incineration, which contributes to greenhouse gas emissions. Enzymatic depolymerization shows potential for treating low-quality PET by breaking it down into high-quality monomers. This study critically evaluates the environmental and economic feasibility of enzymatic depolymerization as a sustainable recycling method for low-purity PET waste. Accordingly, life cycle assessment (LCA) and life cycle cost analysis (LCCA) were applied to comparatively assess enzymatic depolymerization (at lab and pilot scale), mechanical recycling, and incineration. The comparison is based on a functional unit of 1 tonne of low-purity PET waste within the European Union in 2024. The Environmental Footprint (EF) 3.1 method within the EASETECH software quantifies environmental impacts across five specific scenarios, addressing climate change potential. Enzyme production was identified as the main environmental hotspot, with significant impacts from inorganic chemicals at pilot scale and organic chemicals in laboratory scenarios. Findings at pilot scale indicate that enzymatic depolymerization can reduce greenhouse gas emissions by over 2500 kg CO2-equivalent per tonne compared to incineration, presenting a clear environmental advantage. The LCCA indicates that capital expenditures (CAPEX) are largely dominated by equipment installation and procurement costs, due to the need for advanced, machinery. Operational expenditures (OPEX) are dominated by enzyme synthesis costs, especially for Isopropyl-ß-D-thiogalactopyranoside (IPTG), which is essential in enzyme production. Additionally, the generation of valuable by-products, such as terephthalic acid (TPA) and ethylene glycol (EG), enhances both the environmental and economic viability of enzymatic depolymerization over traditional recycling methods. Despite scalability and data precision challenges, the findings suggest that enzymatic depolymerization offers a promising pathway toward circular economy goals. Optimizing chemical inputs and reducing costs are critical for advancing this approach to widespread application. This comprehensive analysis provides valuable insights into the potential for enzymatic PET recycling to drive sustainable waste management and significantly contribute to circular economy objectives.

5.10.P-We472 Processing of Wastewater Sludges From Plastic Recycling: An Lca Perspective

***Kamila Sirotna**[1], Lubor Laichman[2], Eva Domincova Bergerova[3] and Radek Prikryl[4], (1)University of Chemistry and Technology Prague (UTC), Czech Republic, (2)ASIO Tech s.r.o., Czech Republic, (3)CPS, Tomas Bata University Zlin, Czech Republic, (4)Brno University of Technology, Czech Republic*

The recycling of flexible low-density polyethylene (LDPE) foils often requires prewashing, which leads to the production of wastewater sludges with high plastic content. Using these sludges for alternative end-of-life applications rather than landfilling or incineration is desirable but poses the question of the efficiency and sustainability of such solutions. Generally, the most researched use of wastewater sludges is in the production of construction materials.

Three such production methods were developed and tested on wastewater sludges from a recycling facility in Central Bohemia, whose dedicated wastewater treatment line produces two types of high plastic content sludges with different compositions. These three applications are: a clarifier in brick production, a filler in concrete production, and an input for plastic roof tile production. This study evaluates the sustainability of each of those three newly developed applications using life cycle assessment (LCA). The environmental

impacts of these applications are assessed in the cradle-to-gate system boundaries using the EF 3.1 methodology. Each application is evaluated including possible benefits, e.g. resource savings compared to the original production method. A suitable mix of waste sludge management methods is presented that promises the most benefits and therefore the least environmental impact.
The LCA results show that for some of these applications, such as clarifier in brick production, the benefits are undeniable. For other applications, the benefits are heavily dependent on the energy consumption and choice of particular production methods. A thoughtful combination of these applications with consideration of their environmental impact could bring efficient utilization of sludges, thus saving of resources. Additionally, the perspective of environmental impact assessment highlights the potential for scale-up and opens the horizon for industrial application.

Disclaimer/Disclosure: This project was co-financed by the Technology agency of the Czech Republic under the TN02000051 Progamme.

5.10.P-We473 Environmental Impacts of a Circular Textiles Ecosystem in the UK with Automated Sorting and Fibre-to-Fibre Recycling

***Sarah Key**, Sarah Gray, Cristina Sabaiduc and Fergus Dowling, WRAP, United Kingdom*

Currently around 750,000 tonnes of non-reusable post-consumer textiles are generated in the UK every year, with just under 390,000 tonnes of this being disposed of directly through residual waste streams into landfill and incineration. At the same time, textile production is only increasing, with a reliance on virgin materials, since only 1% of textiles are currently recycled back into textiles. Balancing this out and closing the loop requires innovation in collection of post-consumer textiles, sorting and fibre-to-fibre recycling, but the environmental impacts of such a system change are unclear. This project looks at the impact of one potential solution, widespread automatic sorting facilities, feeding into scaled-up fibre-to-fibre recycling processes within a fully circular textiles ecosystem. Through collecting both primary and secondary data covering the full system, a Life Cycle Assessment (LCA) was conducted to understand the overall impacts and benefits, and identify hotspots in this that requires further innovation and development. Results suggest that overall, the system has great potential for providing environmental benefits, but there are several important considerations that will need to be taken into account on the transition to ensure these benefits can be realised. Firstly, recycled content targets for brands and retailers need to consider the virgin material production that will be required for blending with recycled fibres to achieve quality and durability. Secondly, there will need to be a diversity of solutions to balance out the hotspots in impacts for different technologies. For example, chemical recycling may have higher impacts, but more useful products, than mechanical or thermo-mechanical closed-loop recycling. Conclusions from this research have been distilled into a wider business case considering economic and social impacts as well as environmental. Findings from this work have not been confirmed, but will feed into planning for the development of a circular textiles system with investors, policymakers and businesses.

Disclaimer/Disclosure: This work has been funded jointly by Innovate UK through the ACT (Automated-sorting for Circular Textiles) UK project and Textiles 2030.

5.10.P-We474 Advanced Analytical Strategies for Recovering Technology-Critical Elements from E-Waste: A Path Toward Circular Economy

*Ole Klein, **Tristan Zimmermann** and Daniel Profrock, Helmholtz-Zentrum Hereon, Germany*

In our rapidly advancing technological world, the demand for technology-critical elements (TCEs) such as gallium, germanium, indium, niobium, rare earth elements, and tantalum has dramatically increased. Yet, without efficient recycling, these valuable materials become inaccessible after their life cycle, leading to resource inefficiency. This is particularly critical for electronic waste (e-waste), often referred to as an "urban mine" for its immense but underutilized resource potential. Accurately determining TCE concentrations in e-waste is crucial to unlocking its economic value and supporting sustainable recycling aligned with circular economy principles.

This study addresses the analytical challenges posed by the complex chemical matrices of e-waste materials, including printed circuit boards (PCBs), light-emitting diodes (LEDs), and lithium-ion batteries (LiBs). Using a combination of digestion-based inductively coupled plasma mass spectrometry (ICP-MS) and laser ablation ICP-MS (LA ICP-MS), we developed a robust methodology for precise elemental analysis. Optimized microwave-assisted acid digestion, with a mixture of 1 mL HCl, 3 mL HNO3, and 1 mL HBF4, achieved high accuracy and recovery. This method enabled the quantification of 58 elements, including valuable TCEs like Cu, Li, and Ni, with significant economic implications. For example, Cu in

PCBs was measured at 112,000 mg/kg (8.99/kg), and Li in LiBs at 21,000 mg/kg (8.34/kg), yielding total values of 15.80/kg for LiBs, 16.14/kg for PCBs, and 5.71/kg for LEDs.

However, the heterogeneity and complexity of e-waste requires alternative techniques. To complement the digestion results, LA ICP-MS was used, which allows almost direct analysis of solid samples. Combining the strengths of both methods, this dual approach increases reliability and precision, overcoming the limitations of digestion while also providing spatial resolution and ensuring validity of results.

The findings contribute to a deeper understanding of how advanced analytical techniques can support resource management practices. By bridging technical challenges and broader goals such as resource efficiency and sustainability, this study offers practical insights into unlocking the potential of urban mining while supporting the transition toward a circular economy.

5.10.P-We475 Environmental Cost-Benefit Analysis of Zero Waste Cosmetics

Marta Belfiore[1], Uros Novak[2] and ***Milica Velimirovic***[1]*, (1)Flemish Institute for Technological Research (VITO), Belgium, (2) National Institute of Chemistry, Slovenia*

More than 350,000,000 tons of plastic waste are produced every year, and a large part of them can end up mismanaged and eventually reaching water bodies. In these environments, plastics break down into micro- and nanoplastics, contaminating water that is recirculated for our daily uses and harming marine and river ecosystems. To address this issue, numerous plastic-free products have been developed in recent years. However, selecting the best options for production and purchase remains a challenge.
The outputs of Life Cycle Assessment (LCA) in terms of Environmental Footprint can be the answer to provide specific information about the magnitude of the different impact categories of the whole life cycle of different products. Moreover, whenever it is possible to turn these impacts into costs thanks to specific monetization factors it is also possible to include LCA results in a wider costs-benefits analysis of the products. When this happens, LCA plays a double role for decision making and reporting, providing essential information both in environmental and economic terms. This use of LCA can be helpful for a more effective comparison between different products that have the same function.
In this study, the comprehensive cost-benefit analysis (CBA) of solid shampoo balls will be presented as an example of double contribution of LCA. This product consists of a plastic-free alternative to liquid shampoo that eliminates the need for plastic packaging, and which features a less polluting chemical formulation. As such, it will contribute to the valuable insights into plastic-free alternative products for informed decision-making by different stakeholders. As an example, CBA can provide a foundation for (i) manufacturers and producing companies that need to understand which options are the most feasible, both practically and economically, (ii) investors that need to understand which technologies will create less damage to the environment, in order to ensure a higher reputation and a lower investment risk, and (iii) customers in order to understand which products of daily use may be the least impacting for their own health and the environment.

Disclaimer/Disclosure: The authors acknowledge financial support from the European Union s HORIZON EUROPE innovation program for the project REMEDIES awarded under Grant Agreement No. 101093964.

5.10.P-We476 Comparing Past and Future Organic Waste Management Approaches for Montreal (Canada) Using Life Cycle Assessment

Sadie MacDonald[1]*, Benjamin Goldstein[2] and Grant Clark[1], (1)McGill University, Canada, (2)University of Michigan, United States*

Canada is moving towards a low-carbon and circular economy by increasing diversion of organic residues to composting and anaerobic digestion. Diverting organic residues from landfills can reduce greenhouse gas emissions associated with the biological decomposition of organic matter. However, the carbon footprint and other environmental impacts of organic waste management systems in Canada are currently poorly understood. The goal of this research is to quantify the environmental impacts of the present and future organic waste management scenarios for Montreal using Life Cycle Assessment (LCA). In the past scenario, organic waste was transported away from the urban center and treated by open windrow composting. In the future scenario, organic waste will be managed by a combination of closed tunnel composting and anaerobic digestion, embedded within the metropolitan area. The Solid Waste Optimization Life Cycle Framework in Python (SwolfPy), an open-source waste LCA software using Brightway2, was used to perform the life cycle inventory modeling and impact assessment calculations. Our analysis reveals distinct tradeoffs between different treatment regimes. For instance, reductions in emissions from transporting waste outside the city can be counteracted by those from energy inputs to maintain closed tunnels and run the anaerobic digestion process. By identifying these and other tradeoffs, this analysis addresses longstanding knowledge gaps in the treatment of organic waste in Canada and supports informed, sustainable management of urban waste streams in the country and beyond.

5.10.P-We477 3D Printed Artificial Reefs: LCA and LCC Analysis to Compare Traditional Cementitious Mortars and Innovative Mixtures Made From Bivalve Mollusk Shells

Letizia Caroscio[1]*, Edoardo Teresi*[1]*, Cristian Chiavetta*[2] *and Alessandra Bonoli*[1]*, (1)University of Bologna, Italy, (2)ENEA - Italian National Agency for New Technologies, Energy and Sustainable Economic Development, Italy*

Restoring marine biodiversity is a crucial challenge to ensure healthy ecosystems capable of counteracting the loss of the global ecological network. Integrating circular economy practices into habitat recovery helps the reduction of the environmental impact, the optimization of resource use, and the implementation of systemic sustainability. This study presents a comparative analysis of the environmental and economic performance of 3D printed artificial reefs, made either from traditional cementitious materials or from an innovative composite derived from the reuse of mussel shells.

The reefs, designed for the repopulation of the native European flat oyster Ostrea edulis, aim to improve local marine biodiversity and regenerate compromised marine habitats. The circular economy approach utilizes waste shells from mussel and oyster farming, transforming them into a valuable resource to replace natural aggregates in construction materials. The innovative material consists of a high percentage of shells, which are over 90% composed of calcium carbonate, making them a sustainable alternative to traditional construction materials.

The Life Cycle Assessment (LCA) will evaluate the environmental impacts of the materials, comparing conventional cement mortar with the shell-based innovative material. A cradle-to-gate approach will be adopted, analyzing the impacts related to raw material extraction, processing, transport, and use. The European footprint method will be applied, considering its environmental impact categories. In parallel, the Life Cycle Costing (LCC) analysis will provide a comprehensive economic perspective to assess the foundations needed to establish a value chain for the valorization of a bio-material.

The project aims to generate concrete data to promote the use of sustainable materials in marine regeneration. The planned analyses will help identify optimal scenarios for marine ecosystem restoration, balancing costs and environmental benefits, and highlighting how the principles of sustainability and circularity can be integrated into conservation and technological innovation projects.

5.10.P-We478 Life Cycle Assessment of UK Household Leftovers: Implications for Storage and Disposal Choices

Yiming Sui*, Eugene Mohareb and Stefan Smith, University of Reading, United Kingdom*

Household food loss and waste (FLW) contributes 18 million tonnes of CO?-eq greenhouse gases (GHG) emissions annually in the UK. Almost 30% of them are well-cooked but not consumed, which is commonly referred to as leftover . Only less than one-third of leftovers is disposed through low-emission options such as anaerobic digestion (AD) or home composting. Consequently, it is necessary to store and eat leftover, which extending shelf-life of leftovers and minimising waste amount. Additionally, it helps to cut down on the need of prepare new meals, which in turn reduces the upstream production and associated emissions.
In this study, the life cycle assessment (LCA) method is conducted to evaluate the environmental impacts of household leftovers in the UK, comparing between storing and re-consuming 1 kg of leftovers, versus disposing of them as biowaste through AD and preparing a new meal. Additionally, different storage methods are assessed to identify the most suitable one for saving leftover. Furthermore, sensitivity analyses are applied to account for variations in national electricity grids and cooking methods, to assess the extent to which these factors influence the decision of preserving leftovers.
Results show that there are 3.95 kg CO?-eq GHG emissions during the AD process, which is 2.23% reduction compared to cooking a new meal. This means the current UK choice of AD as the main biowaste disposal method is acceptable. However, the offsets from disposal process are minimal, with the main input are from upstream processes of leftover, such as production. Therefore, storing and re-consuming leftover results in significantly lower emissions compared to new meal. For instance, storing leftovers in glass containers produces 0.046 kg CO?-eq emissions, accounting to a 98.9% reduction. Sensitivity analysis reveals that, when considering different reheating methods, reheating on gas stoves offers averagely 32% more benefits than using microwaves. Furthermore, due to the electricity usage of refrigerator and reheating, electricity grids also affect the emissions, vary from a 70% reduction to a 200%

increase. Generally speaking, despite these variations, the emission reductions achieved by storing and re-consuming leftovers consistently exceed 95% compared to preparing a new meal, indicating that the effective strategy to mitigate environmental impact of leftover is to store and re-use them, rather than relying on other disposal methods.

5.10.P-We479 Life Cycle Assessment (LCA): Conventional Thermal Energy Storage (TES) System Versus Alternative Steel Slag-Based System for Concentrating Solar Power Plants (CSP)
Carlos Alberto Vielma Leal*, Marc Majo, Alejandro Calderon, Adela Svobodova-Sedlackova, Ana I. Fernandez and Camila Barreneche, University of Barcelona, Spain*
Thermal Energy Storage (TES) plays a crucial role in advancing decarbonisation. Its integration into Concentrated Solar Power (CSP) plants can significantly enhance efficiency and support renewable power generation. The primary commercial TES material, solar salt (SS), presents technical challenges and has the highest environmental impact in TES systems. An innovative alternative is Electric Arc Furnace Steel Slag (EAFSS), a steel industry waste that can be repurposed as TES material. However, the environmental sustainability of EAFSS for TES applications has not been comprehensively studied. This research quantified the environmental impact of a thermocline TES system using EAFSS as a filler material, compared with a conventional SS system. A Life Cycle Assessment (LCA) examined EAFSS environmental burdens employing mass and economic allocation methods. The LCA scope encompassed a "cradle-to-gate" perimeter, which covers the manufacturing stage of a CSP tower plant. The results showed that EAFSS provided the same storage capacity as the conventional system while reducing 9% the TES' material intensity. At the TES system level, the ReCiPe method indicated impact reductions of 21% using mass allocation and 53% with economic allocation. When using mass allocation, the global warming emissions were 49% higher (127 kg CO2eq/kWh) than in the conventional TES system (85 kg CO2eq/kWh), which may benefit steelmaking industries by attributing a large share of their emissions to CSP plants. In contrast, economic allocation yielded lower emissions (58 kg CO2eq/kWh), providing more credit to recycling EAFSS in TES systems. These findings underscore the potential of EAFSS to enhance CSP sustainability while valorising waste/by-products to generate greener electricity.

5.10.P-We480 Safe and Sustainable Recycling of Solar Panels: A Scenario Study
Johannes Lijzen[1]*, Frieke Heens*[1]*, Martijn van Bodegraven*[1] *and Erik Dekker*[2]*, (1)National Institute of Public Health and the Environment (RIVM), Netherlands, (2)Province Gelderland, Netherlands*
To assess and stimulate safe and sustainable recycling the National Institute of Public Health and the Environment (RIVM) developed a screening methodology to assess the circularity, environmental impact and safety of recycling of waste flows. This method was applied on the case of recycling of End-of-Life solar panels. It is expected that the first generation of solar panels will start to be taken out of use in large numbers in five years time. Various technologies to recycle solar panels are being developed.
The aim of this study was to investigate which recycling options appear to be feasible, how environmentally friendly they are and to learn how the screening methodology can help to make a comparison. We compared four future scenario s to the current situation (the baseline), in which no raw materials from End-of-Life solar panels are recovered, but are shredded and processed for a low-grade applications like road foundation. Three screening modules were applied for quantifying the circularity, environmental impact and the safety due to the presence or emission of substances of concern (SoC). Our analysis shows that all future options are more circular and have a lower environmental impact than the baseline. One scenario scores best on climate change (CO2-eq.), but all are much lower than the baseline. One of reasons is that it costs more energy to process new raw materials into solar panels than to use recycled raw materials. The option in which glass is recycled into new solar panel glass and the silicon can be recycled to high grade silicon, has also the highest value for the circularity indicator 'efficiency'. In the recycling process, attention should be paid to hazardous substances in solar panels: lead, antimony and per- and polyfluoroalkyl substances (PFAS). Lead is contained in soldering materials and antimony is added to make the glass brighter. The backsheets contain fluoropolymers, as a result of which PFAS can be released when they are incinerated. This can lead to human and environmental exposure, depending on how substances are released.
Based on this study we advised the national government to stimulate specific technological developments that enable high-grade recycling of solar panels. We also recommend to stimulate design for recycling. For example developing other encapsulant materials between the glass and the backsheet enables easier dismantling. It is also important to minimise the use of hazardous substances lead and PFAS.

5.10.P-We481 Bottom-Up, Dynamic Probabilistic Material Flow Analysis of Japanese Plastic Flows as an Initial Step to Understand the Chemical Additives Flows and Stocks
Yiwen Zhang[1]*, Zhanyun Wang*[1]*, Masahiro Oguchi*[2]*, Haruhisa Yamamoto*[2] *and Bernd Nowack*[1]*, (1) Empa*

- *Swiss Federal Laboratories for Materials Science and Technology, Switzerland, (2) National Institute for Environmental Studies, Japan*
The global production of secondary plastics has increased more than tenfold in the past two decades, creating a strong backflow from end-of-life (EoL) products to manufacturing. Secondary materials can substitute pristine resins in manufacturing, and therefore mitigate many of the related environmental impacts. However, the associated risks of secondary materials, particularly from the additives that persist through recycling processes, are not yet fully understood. Tracking the flows of chemicals in secondary materials requires high-resolution data on plastic flows. As a first step of achieving so, this study presents a dynamic probabilistic material flow analysis of plastic flows, with high granularity at the EoL stage. Japan was selected as a case study, due to the availability of comprehensive data. We compiled the production, trade, and consumption data for eight major types of commercial polymers for the period from 1950 to 2023. The amounts were allocated to 48 product categories following a bottom-up approach based on the annual sales data and the polymer composition of these products. Using the consumption data and lifetime distributions, we estimated waste generation for individual product categories. Twenty-three collection pathways were differentiated across general waste collection, industrial waste collection and sorted collection for specific product categories that are regulated under existing waste laws and/or managed by various industrial associations. The inputs and outputs of mechanical recycling were modeled accordingly. Our results show a significant increase in recycling activity following the establishment of respective recycling laws. However, the absolute quantities of secondary plastics remain relatively low compared to those that were sent to energy recovery and landfill. Secondary materials primarily originate from containers and packaging, electronics, and motor vehicles. These findings provide initial insights into the types of secondary polymers and chemicals likely present therein, forming a basis for future quantification of the flows of chemical additives and their environmental and human health impacts.

5.11.A Food for Thought: How Do We Move Towards a Safe and Sustainable Global Food System?

5.11.A.T-01 Towards Sustainable Agri-Food Systems: Environmental Benefits of Climate-Smart Agriculture in Norway

Narie Rinke Dias de Souza*, Marte Kristiane Mohn Solberg, Xiangping Hu and Francesco Cherubini, NTNU Industrial Ecology Programme, Norway*
Climate-smart agriculture (CSA) practices aim at contrasting land degradation and enhancing climate resilience to ensure safe and sustainable food systems. The environmental benefits of CSA often go undetected and appear negative in life cycle assessment (LCA), which typically focuses on product-based outputs, overlooking ecosystem services and resilience. We explore how CSA can be better represented in LCA of agricultural practices by investigating barley production on cropland at risk of soil erosion in Norway under three management scenarios: conventional agriculture, integration of winter cover crops, and establishment of trees as buffer zones. The assessed environmental impacts combine ecosystem services (reduction of soil erosion, habitat quality, carbon sequestration) with traditional life-cycle impact categories (climate change, freshwater and marine eutrophication, human toxicity, terrestrial acidification and freshwater ecotoxicity). Relative to the conventional barley production system, buffer zones improve all environmental impacts (26% on average) and cover crops all but terrestrial acidification (10% on average), when using a land-based functional unit. When a product-based functional unit is used, buffer zones still perform better than conventional farming (but relative benefits are reduced to 21% on average) while cover crops show higher impacts in five impact categories (and the average benefit is decreased to 8%). Both approaches always deliver higher ecosystem services under both types of functional units, despite the lower crop yields. Specifically, buffer zones and cover crops increase habitat quality, terrestrial carbon storage and reduce nutrient and soil-particle runoff, thereby supporting long-term yields and improving the circularity of this food system. Reduced short-term yields of the main crops remain a barrier to CSA adoption. Identifying the environmental advantages of these practices can provide evidence to support the transition to more safe and sustainable agricultural systems.

5.11.A.T-02 Using Large-Scale Farm Surveys to Identify Productivity and Sustainability Solutions

Juliet Telfer[1]*, Joseph Poore*[1]*, Patrik Henriksson*[2]*, Guillaume Royer*[3]*, Tek B. Sapkota*[4]*, Anton Urfels*[5]*, Timothy J. Krupnik*[6]*, Noufa Cheerakkollil Konath*[7]*, Andrew J. McDonald*[8] *and Virendar Kumar*[5]*, (1) University of Oxford, United Kingdom, (2)Leiden University, Netherlands, (3) University of Oxford, France, (4)CIMMYT, Mexico, (5)IRRI, Philippines, (6)CIMMYT, Bangladesh, (7)CIMMYT, India, (8)Cornell University, United States*
India is one of the world s largest crop producers, with its agricultural sector being responsible for 18% of its total national emissions. Life Cycle Assessments (LCAs) are crucial for attributing environmental impacts to specific products and farms and identifying areas where impacts can be reduced. However,

there has been little work so far on converting LCA results into sustainability improvement advice for farmers. Farmers need reliable, up-to-date information on mitigation measures they can adopt, and how such measures may affect other important areas such as crop yield. This research focuses on converting large-scale agricultural survey data into LCA results, and then using these results to create mitigation solutions for farmers. Specifically, we use farm survey data from the International Maize and Wheat Improvement Centre (CIMMYT), covering over 30,000 crop production cycles, 22 unique crops, and site locations spread across India. We format the data and then upload it onto HESTIA, a platform that archives and makes available food production and impact data in a consistent format. HESTIA has over 500 models available which automatically gap-fill the data (for example by calculating diesel inputs based on the operating hours of machinery) and calculate emissions, resource uses, and characterised indicators for every crop cycle. We generate univariate distributions of production practice and environmental impact data, which enables us to identify plausible ranges of inputs, crop yields, and emissions. We also generate multivariate distributions, allowing us to understand how one variable (e.g., fertiliser or soil type) varies with another (e.g., crop yield), which then allows us to identify the main sources and drivers of impacts. Using these results, we generate profiles of what the lowest environmental impact farms look like in each region based on current practices. Finally, we go beyond this to use sensitivity analysis to include new production practices (e.g., zero tillage, agroforestry, or zero crop residue burning) to explore how environmental impacts could be further reduced. Overall, this allows us to create a list of possible mitigation options for any given farm in India. Our approach is scalable and extensible to other farming systems, and we demonstrate this by applying our methods to data from another large farm survey (~40,000 rice farms in India, Nepal, and Bangladesh), that is a part of the Landscape Crop Assessment Survey (LCAS).

5.11.A.T-03 Can 'Superfoods' Bridge Nutritional Gaps and Promote Environmental Sustainability in Spain? A Proposal for a Context-Specific Nutritional Model in Life Cycle Assessment
***Ana Fernández Ríos**, Jara Laso, Ruben Aldaco and Maria Margallo, University of Cantabria, Spain*
The overriding connection between climate interactions and nutritional outcomes of food systems is at the forefront of research, especially when it comes to assessing alternative food products. To address this issue, significant progress is being made in the field of nutritional life cycle assessment (LCA), with the development of novel methodologies and specific approaches garnering increasing attention within the LCA community. In this context, the objective of this investigation is to design a nutritional index, namely nutrient profiling (NP) model, adapted to the Spanish context for use in nutritionally-factored environmental life cycle assessments of superfoods .
The development of the NP model is based on iterative decision-making, where design characteristics such as the objective, the type of model, the criteria or the nutrients included have to be decided. The nutrient rich family of models is taken as basis for our system, and the specification is guided by the contextualization. Qualifying and disqualifying nutrients are selected based on the critical nutritional shortfalls of the Spanish population and associated health outcomes, and weighting factors are included motivated by the capacity of superfoods to meet recommendations.
The integration of the features gives rise to the Spanish Nutrient Rich (super)Food 9.2 (sNRF9.2) model, which proves its validity by aligning with the Spanish Public Health Strategy and other NP models. The application of the model as functional unit in LCA studies of super and conventional foods shows its usefulness in conveying integrated information efficiently. Trends reveal a conflicting situation for a wide range of products, including fruits, fish, cereals, and vegetables, where greenhouse gas emissions are low, but so is the nutritional quality of the food. In contrast, nuts, seeds and legumes represent the best alternative for its good nutritional-environmental balance. Among all products tested, two superfoods , namely, oat and carob seeds, are located at the top ten of the ranking, evidencing the potential of alternative nutrient sources. However, despite the model's applicability and versatility, it is important to acknowledge the need for periodic updates to accurately reflect the environmental and nutritional landscape in Spain.

5.11.A.T-04 Safety of Circular Food Systems: Understanding the Fate of Chemicals
***Stefan PJ van Leeuwen**, Kerstin Kratschmer, Ine van der Fels-Klerx and Katja CW van Dongen, Wageningen Food Safety Research (WFSR), Netherlands*
The re-use of residual streams in the food system becomes more important, especially to close agricultural production loops. Residual streams contain nutrients, which can be re-introduced in the food system. However, besides nutrients, chemical or microbial hazards may also be present in residual streams which then can be re-introduced or accumulate in the circular food system.

One potential useful residual stream to use as a nutrient source to close agri-food production loops is

sludge. Sludge of wastewater of domestic origin (STP) as well as sludge of wastewater of the agro-food industry (FTP) were collected in The Netherlands, and has been characterized for their presence of chemical, microbial, and physical hazards. The sludge can again be used as a nutrient source in multiple circular food systems. In this study, the application of the sludge samples as a nutrient source for edible insect rearing (black soldier fly larvae; Hermetia illucens) was evaluated. The fate of multiple chemical hazards was evaluated. These included heavy metals and trace elements, of which especially cadmium accumulated in the black solder fly larvae, with bioaccumulation factors all exceeding 1. Also, the presence and fate of short chained and some longer chained per- and polyfluoroalkyl substances (PFASs) was evaluated. Highest concentrations in the sludge samples were determined for trifluoroacetic acid (TFA), which were detected in only some of the corresponding insect larvae samples, in which no bioaccumulation was reported (bioaccumulation factor <1). Longer chained PFASs, such as PFOA, PFOS, PFHxS and PFNA, were evaluated to bioaccumulate in the black soldier fly larvae in most of the exposure conditions. Bioaccumulation factors were generally highest for PFOS. This corresponded to findings of another study in which black soldier fly larvae were exposed to these four PFASs single and in mixture, due to spiking of the start substrate (van Dongen et al., in preparation). This also resulted in bioaccumulation of all these four PFASs, with highest bioaccumulation factors for PFOS.
Altogether, this study provides better insights into the fate of contaminants in a circular food production system, based on insect rearing for the production of alternative proteins.

The European Union is gratefully acknowledged for supporting the insect studies (SUSINCHAIN project; H2020 grant agreement No 861976). Several colleagues of WUR are gratefully acknowledged for sampling, chemical analysis and data evaluation.

5.11.P-Th348 Assessing Impacts on Biodiversity on an Aquaculture Portfolio

*Aurore Wermeille[1], **Anne Asselin**[1], Robert Parker[2], Jill Swasey[3] and Maxime Engler[4], (1)Sayari, France, (2)Aquaculture Stewardship Council, Canada, (3)Aquaculture Stewardship Council, United States, (4)Aquaculture Stewardship Council, France*

The increasing global demand for sustainable practices is pushing companies to better assess and disclose their environmental impacts, particularly on biodiversity. In Europe, the Corporate Sustainability Reporting Directive (CSRD) reinforces this need by requiring businesses to report on their biodiversity impacts. In the seafood sector, aquaculture plays a central role by surpassing production from capture fisheries and contributing nearly 60% of seafood produced globally. However, reliable biodiversity data remain limited, and existing third-party sustainability certifications, such as those from the Aquaculture Stewardship Council, cover less than 4% of global aquaculture production.
To support companies falling under the scope of this directive, we developed a qualitative, risk-based method to assess biodiversity impacts across aquaculture portfolios. The approach considers IPBES's (Intergovernmental Platform for Biodiversity and Ecosystem Services) five drivers of biodiversity loss and focuses on two key stages of the value chain: feed production and farming practices. In total, eight indicators are qualitatively evaluated to assess risks from "cradle to farm gate."
We tested this methodology on two key aquaculture species: Atlantic salmon (Salmo salar) and Whiteleg shrimp (Litopenaeus vannamei), spanning diverse practices including ASC certified operations and more traditional (non-certified)) and countries of origin. Results revealed notable differences in biodiversity impacts between sustainable and conventional production methods. Certified products consistently demonstrated lower risk levels, providing evidence of best practices due to the strict requirements, burden for evidence and supply chain assurance that are part of the ASC certification program. The model emphasizes key impact areas (e.g. deforestation, pollution, fishing pressure) and enables companies to pinpoint risks, prioritize mitigation measures, and guide strategic decision-making. Our risk-based approach fills a critical gap in biodiversity data and provides a scalable framework for aquaculture portfolio assessment. It supports businesses in gradually improving their biodiversity knowledge and aligning with CSRD requirements.
Further pilot studies are underway to refine the methodology, including the consideration of indicator weighting and cumulative scoring mechanisms. These advancements aim to drive meaningful improvements toward more sustainable aquaculture practices.

5.11.P-Th353 A Sustainable Transportation System Will Require Sustainable Dietary Patterns and Food Systems: Focus On Cycling Life-Cycle Impacts Including Additional Calories Intakes and Regional Diet Evolutions

Anne de Bortoli[1]*, Susie Ruqun Wu*[2]*, Viviane Blanc*[2]*, Cecile Sophie Marie Bulle*[2] *and Catherine Houssard*[2]*, (1)Polytechnique Montreal, Canada, (2)UQAM, Canada*
Increasing active mobility cycling, walking seems a promising lever to mitigate impacts to climate change, but switching to active modes requires to produce more food to supply additional calorie intakes (ACI). Accounting for more than 1/3 of the global land distance traveled by passengers, cycling also requires substantial extra calories, making its environmental impacts intrinsically linked to food system s sustainability. This study aims to explore (a) the life cycle impacts of different cycling practices by region and type of bike including ACIs, and (b) the share of cycling environmental impacts in prospective mobility scenarios under different archetypical regional diet evolutions.
The method is based on : (1) modeling scenarios of global future transportation demands for land passenger travel, (2) conducting the LCA of transportation modes, (3) assessing the environmental impacts of the scenarios. (1) is an extrapolation of the International Transportation Forum scenarios, where technologies by mobility mode are completed using other sources. In (2), we develop regional archetypes of conventional modes to conduct prospective LCAs using premise. We gather existing and develop new life cycle inventories of bikes (electric/mechanical (e-/m-), standard/sportive/cargo, aluminium/bamboo/carbon), model calories consumed depending on regional cycling practices (speed/intensity) using the Metabolic Equivalent model, as well as different dietary patterns (vegetarian, keto, 6 average regional diets), to calculate the life cycle impacts of different cycling practices and transportation scenarios using IMPACT World+ (3).

Cycling environmental impacts change highly when considering ACI. The carbon footprint of cycling in Africa goes from 11 to 26 gCO2e/km, while at the other extreme, it jumps to 95 gCO2e/km in Europe. Under a keto diet, cycling with a m-bike emits 135 gCO2e/km, what is like using an e-car with a green electricity. Under highly emitting diets, e-bikes perform better, but e-biking or m-biking emits similarly under a vegetarian diet (35 g). Under stable diets and food systems but high decarbonization ambitions in the transportation sector, cycling would reach by mid-century 1/6 of the contributions of the global land transportation to CC and water scarcity, and 1/3 to its land occupation and marine eutrophication, mostly due to ACIs. Becoming all vegetarians mitigates some impacts but may make the contribution to water scarcity explode.

5.11.P-Th363 Chemicals of Concern in Food Packaging: A Matter of Sustainability
Birgit Geueke, Justin Michael Boucher, Etienne Cabane, Lindsey V. Parkinson, Helene Wiesinger and ***Jane Muncke****, Food Packaging Forum, Switzerland*
In a globalized system, food is increasingly processed and transported over long distances. This is enabled by highly functional food packaging. However, food packaging is also a driver of long-term damage to the environment and human health. From the sourcing of raw materials over production to end-of-life, food packaging has multiple impacts on the use of resources, environmental pollution, and exposure to chemicals. Therefore, decision makers in the food sector need transparent and science-based information to choose safe and sustainable food packaging for each type of food.

The UP Scorecard was developed for this purpose and is built on a scoring system, including the six impact areas climate change, water use, plastic pollution, sustainable sourcing, recoverability, and chemicals of concern. While other packaging assessment tools are available, they often focus on a single impact area, such as climate change, but usually omit the chemical safety of a material.

To assess chemicals of concern within the UP Scorecard, we applied a hazard scoring system to over 14,000 known food contact chemicals (FCCs), based on the methodology described in the PlastChem report (DOI: 10.5281/zenodo.10701706). We focused on the human health hazards only, as there is direct oral human exposure from the many chemicals that migrate from packaging into foodstuffs. In total, we found 4680 FCCs with hazard scores indicating different levels of concern for human health. 419, 121, and 406 out of these FCCs have the highest hazard score for carcinogenicity, mutagenicity and reproductive toxicity, respectively, whereas 45 FCCs are confirmed endocrine disrupting chemicals, and 1330 FCCs have specific organ toxicity.

To facilitate access to this information for decision-makers, such as procurement professionals, we grouped the chemicals of concern based on their structural properties but also integrated filtering options regarding the use and presence of FCCs in food contact materials. This will help to identify, screen and avoid the most hazardous chemicals for each food packaging material and support development of safe and sustainable food packaging solutions.

5.11.B Food for Thought: How Do We Move Towards a Safe and Sustainable Global Food System?

5.11.B.T-01 Contribution of House Gardening Towards Sustainable Food Systems in the EU

Jan Matuštík, *Aurore Guillaume and Vladim r Koc, Department of Sustainability and Product Ecology, University of Chemical and Technology in Prague, Czech Republic*

The food system stands at the intersection of many environmental crises, and it needs to transform both to mitigate environmental impacts, as well as to adapt to the changes in Earth System functioning. House gardening can be an important piece of the puzzle of a sustainable food system, yet there are currently lacking larger scale quantitative assessments of environmental consequences of a widespread adoption of gardening. In this study we aim to fill this gap and evaluate what role house gardening can play in the EU. We map the area potentially usable for house gardening in the EU27 states based on OpenStreetMap data. We evaluate the life cycle environmental impacts of vegetable cultivation in gardens and quantify the potential benefits of substituting conventional vegetable production. We compare two scenarios evaluating both direct one-to-one substitution and indirect substitution through market shifts evaluated using the agro-economic model CAPRI. The variability of underlying parameters and gardening practices is captured with a Monte Carlo simulation. The model-mean garden production, assuming 50% utilization of the potential area, is over 200 Mtons of vegetables, a value larger than the EU production and import in 2020 according to FAOSTAT. Based on the results, house gardening could lead to significant benefits across all impact categories. Direct substitution of conventional production could lead to avoidance of 25 Mtons CO2 eq, with the potential benefits of house gardening for climate reduced to 5 Mtons CO2 eq when market consequences are modeled. This study provides the first quantitative estimate of the potential of house gardening for sustainable food system transition in the EU. With the large variability of potential crops and gardening practices, and with the data and knowledge limitations, these values have the character of only rough estimates. Still, we show that the potential role of house gardening in a sustainable food system could be significant, especially considering other, less tangible benefits of gardening.

5.11.B.T-02 Rising Global Species Loss Embodied in Oil Crop Supply Chains

Shuntian Wang *and Stephan Pfister, ETH Zurich, Switzerland*

Oil crop cultivation has emerged as a major driver of global biodiversity loss through demand-driven land use expansion. We quantified the global species loss embodied in oil crop supply chains from 1995 to 2020 by combining spatially explicit biodiversity impact assessments with a hybrid multiregional input-output model, enhanced supply chain mapping, and structural decomposition analysis. Our findings reveal that in 2020, the biodiversity impact from oil crop cultivation land use reached 0.016 global PDF (Potentially Disappeared Fraction), indicating that approximately 1.6% of species would potentially face complete extinction if current land use patterns for oil crop cultivation persisted. Tropical regions accounted for 77% of biodiversity impact from oil crop cultivation, predominantly due to the production of oil palm, coconut, and soybean. We observed significant outsourcing of biodiversity impacts, with increased imports to China, the European Union, and North America driving species loss in producer countries such as Indonesia and Brazil. Global biodiversity impact from oil crop cultivation increased by approximately 83% from 1995 to 2020. Over 90% of biodiversity impact growth from food end-uses stemmed from increased vegetable oil and animal product demand in the Global South, while the European Union dominated both total impact and impact growth in non-food end-uses. Structural decomposition analysis identified rising per capita consumption as the primary driver of increasing biodiversity impacts due to oil crop cultivation. To reduce biodiversity loss, non-food and feed uses of oil crops should be minimized and production in biodiversity hotspots avoided. Our findings underscore the urgent need for policies targeting sustainable production and consumption across global oil crop supply chains and provide a basis informing such actions.

5.11.B.T-03 Pathways to a More Sustainable Swiss Food System: Holistic Assessment Reveals Synergies and Trade-Offs

Thomas Nemecek, *Utkur Djanibekov, Albert Von Ow, Alba Reguant Closa, Vasco Diogo, Melanie Douziech and Gabriele Mack, Agroscope, Switzerland*

The Swiss Sustainable Food Systems (SWISSfoodSys) model allows the evaluation of various future scenarios for the development of the Swiss food system. The model has been completely revised and substantially extended by including economic indicators such as added value, costs and agricultural income, labour requirements, as well as nutritional value and health impacts of different diets. In this contribution, we used the model to assess future dietary patterns and food system optimisation strategies from a holistic perspective.

The SWISSfoodSys model uses a linear programming approach to simulate the development from 2019 to 2050. It includes 43 crop activities, 41 livestock categories, and processed 122 products, imports and

exports. The model integrates the Nutrient Rich Food Index and the Health Nutritional Index to assess the health impact of various diets. For Swiss production we generated Life Cycle Inventories (LCIs) with the Swiss Agricultural Life Cycle Assessment (SALCA) method. For imported goods, we calculated mixes of different countries of origin from available LCI databases, including the transports to Switzerland. SALCA LCIA has been used for the impact assessment.
We simulated a range of dietary scenarios (flexitarian, vegetarian, mix of different dietary patterns) and food systems optimisation scenarios (with different targets). All scenarios account for population growth over time. All dietary scenarios led to significant reduction in livestock production and an increase of domestic food production, thereby improving self-sufficiency. While following dietary recommendations resulted in a reduction of greenhouse gas (GHG) emissions, this was insufficient to meet climate targets. Reduction of food waste led to substantially lower environmental burdens in all scenarios. Additional system optimisation and dietary changes are needed to achieve the climate targets. First results indicate synergies and trade-offs between the different indicators, such as trade-offs between GHG emissions and agricultural income. Achieving a significant reduction in GHG emissions would require reduced livestock production and lower consumption of meat and milk, which would also decrease agricultural income. The SWISSfoodSys model allows to evaluate pathways to a more sustainable food system. By balancing different societal needs, good compromises between the different dimensions can be identified, which increases the chances of their implementation.

5.11.B.T-04 Biodiversity Impacts of Recent Land-Use Change Driven by Increases in Agri-Food Imports

Veronika Schlosser[1]*, Stephan Pfister*[2]*, Stefanie Hellweg*[2] *and Livia Cabernard*[1]*, (1)Technical University Munich, Germany, (2)ETH Zurich, Switzerland*

Land-use change such as the conversion of natural habitat to agricultural land has been a major driver of global biodiversity loss, prompting efforts at biodiversity restoration. However, restoration measures in certain areas can shift the detrimental biodiversity impacts elsewhere through the outsourcing of agri-food supply chains to biodiverse regions. This study examines the link between biodiversity impacts from land-use change and shifts in global supply chains from 1995 to 2022. We combine spatially-resolved land-use change data from 1995 to 2022 with ecoregion-specific global species loss factors from UNEP-SETAC to assess both increases and decreases in biodiversity impacts from land-use change. We integrate this regionalized impact assessment into Resolved EXIOBASE34,5 (REX3), a highly-resolved MRIO database (189 countries x 163 sectors), and introduce a marginal allocation to study the link between shifts in global supply chains and recent biodiversity impacts from land-use change. Our study reveals that over 90% of global biodiversity impacts from land-use change are tied to international trade of agri-food products. Nearly 80% of recent global land-use change impacts were linked to agri-food exports from Latin America, Africa, and Southeast Asia-Pacific (excluding China). Conversely, increased imports to China, the United States, Europe, and the Middle East accounted for nearly 60% of global land-use change impacts, despite these regions experiencing decreased domestic impacts through restoration. This suggests that declining biodiversity impacts in temperate and arid regions are partly achieved by outsourcing agri-food supply chains to tropical biodiversity hotspots. As a result, global species extinction rates have accelerated, with a 1.4% potential species loss since 1995 exceeding the planetary boundary by about fifty times. This highlights the urgent need for policies incentivizing habitat protection and sustainable sourcing in agri-food supply chains.

5.11.P Food for Thought: How Do We Move Towards a Safe and Sustainable Global Food System?

5.11.P-Th346 Rapid Evidence Assessments to Increase Transparency of the Environmental Profile of Agricultural Practices to Inform Sustainability Improvements and Environmental Protection Goals

Christian Bogen*, Bayer AG, Germany*

Background: Agricultural systems are complex, with many interrelated components. Changing one practice to manage an environmental risk or hazard can inadvertently impact other risks and even result in more harmful environmental outcomes. A holistic approach that considers the overall environmental impact of the various management tools and practices will be required to steer agriculture towards more sustainable outcomes.
Challenge: Consequently, environmental risk assessments and their specific protection goals must realistically account for the impacts and adverse effects of diverse practices and seek to minimize trade-offs. The presented comprehensive approach building on rapid evidence assessments (REA) aims at supporting decision-making by revealing both advantages and limitations, and facilitating the exploration of synergies and trade-offs in agricultural practices.

Methods: A bottom-up approach was employed to rapidly review scientific publications on the environmental implications of common cropping tools and practices, such as inversion tillage, across twelve impact categories related to soil, water, climate, and biodiversity. The second phase builds on the REA results and focused on agricultural systems, analyzing the costs and benefits of various management options while considering soil health, climate change, water quality, biodiversity, and land use efficiency. Results: The rapid evidence assessment highlighted key environmental implications of various agronomic tools, making it easier to identify opportunities and trade-offs. When considering an overarching agricultural practice like conservation agriculture numerous environmental benefits but also limitations in temperate climates regarding productivity and land use efficiency were found.
Conclusions: The presented methodology was able to provide a more holistic view of the environmental impacts of various agronomic tools, including inversion tillage, crop rotation, and cover crops. By enhancing the understanding of the consequences of changing agronomic practices, this approach can support the development of outcome-based business models and regulatory approaches that incorporate biodiversity and ecosystem services, guiding decision-making and minimizing potential trade-offs in agricultural production.

Disclaimer/Disclosure: The research was conducted by ADAS, an independent consultancy, with funding from Bayer AG.

5.11.P-Th347 Circular Nutrient Management and Triple Planetary Crisis

***Raghuram Nandula**, Centre for Sustainable Nitrogen and Nutrient Management, Guru Gobind Singh Indraprastha University and Sustainable India Trust, New Delhi, India*

Nutrient chemicals are at the heart of the triple planetary crisis due to their role in pollution, biodiversity and climate change. Nutrients from chemical/industrial/mineral fertilizers and anthropogenic wastes are altering the biogeochemical cycles of N/P/K/S beyond planetary boundaries. As the ongoing international nitrogen and phosphorus assessments quantify the impacts of nutrient pollution, agriculture and waste management are in the spotlight. Intensive agriculture broke the natural circularity of nutrient linkages between crops and livestock, which derived nutrients from each other s wastes. Modern cropping practices in most countries rely excessively on fertilizers for nutrients, while wasting the same nutrients produced naturally by humans and livestock, causing nutrient/waste pollution from crops, livestock and humans. Globally, low fertilizer use efficiency or crops and poor management of livestock manure/urine and municipal wastes together account for most of the anthropogenic ammonia and nitrous oxide emissions to air pollution and nitrates/phosphates/sulfates to water pollution. Nutrient recycling from livestock manure/urine as well as domestic solid and liquid wastes into crop production can minimize fertilizer demand and save nutrient/waste pollution, human health, climate change, biodiversity and ecosystem services. While technologies and best practices are increasingly becoming available, policy frameworks are not yet conducive to fully recycling wasted nutrients and to use fertilizers only as top-up inputs when needed. Recently, UNEP global partnerships on nutrient management (GPNM) and wastewater (GWWI) and the UNEP resolutions on sustainable nitrogen management (UNEA 4/14 and 5/2) generated some intergovernmental attention. Academic, industrial and civil society attention is critical to amplify these initiatives and build up the momentum for sustainable nutrient management. This must begin with the restoration of legume-based multi-cropping and intercropping with other crops, as well as integration of livestock into every possible cropping system. Biological nitrogen fixation by legumes alone can reduce N-fertilizer demand by upto a third, while the rest can be met by recycling nutrients from manure/urine/compost/wastewater with similar crop yields. Further, crop nutrient demands can be reduced by ongoing crop improvement efforts for nutrient use efficiency through selection/breeding. Global/regional/sectoral examples will be shared.

Disclaimer/Disclosure: President, Sustainable India Trust (SIT), New Delhi. This work was supported by GEF-UNEP-INI Project on International Nitrogen Management System and UNEP SSFAs on nutrient recovery from wastewater to SIT, UKRI-GCRF project on South Asian Nitrogen Hub, DBT and GGSIPU-FRGS projects on nitrogen use efficiency

5.11.P-Th348 Assessing Impacts on Biodiversity on an Aquaculture Portfolio

*Aurore Wermeille[1], **Anne Asselin**[1], Robert Parker[2], Jill Swasey[3] and Maxime Engler[4], (1)Sayari, France, (2)Aquaculture Stewardship Council, Canada, (3)Aquaculture Stewardship Council, United States, (4)Aquaculture Stewardship Council, France*

The increasing global demand for sustainable practices is pushing companies to better assess and disclose their environmental impacts, particularly on biodiversity. In Europe, the Corporate Sustainability

Reporting Directive (CSRD) reinforces this need by requiring businesses to report on their biodiversity impacts. In the seafood sector, aquaculture plays a central role by surpassing production from capture fisheries and contributing nearly 60% of seafood produced globally. However, reliable biodiversity data remain limited, and existing third-party sustainability certifications, such as those from the Aquaculture Stewardship Council, cover less than 4% of global aquaculture production.
To support companies falling under the scope of this directive, we developed a qualitative, risk-based method to assess biodiversity impacts across aquaculture portfolios. The approach considers IPBES's (Intergovernmental Platform for Biodiversity and Ecosystem Services) five drivers of biodiversity loss and focuses on two key stages of the value chain: feed production and farming practices. In total, eight indicators are qualitatively evaluated to assess risks from "cradle to farm gate."
We tested this methodology on two key aquaculture species: Atlantic salmon (Salmo salar) and Whiteleg shrimp (Litopenaeus vannamei), spanning diverse practices including ASC certified operations and more traditional (non-certified)) and countries of origin. Results revealed notable differences in biodiversity impacts between sustainable and conventional production methods. Certified products consistently demonstrated lower risk levels, providing evidence of best practices due to the strict requirements, burden for evidence and supply chain assurance that are part of the ASC certification program. The model emphasizes key impact areas (e.g. deforestation, pollution, fishing pressure) and enables companies to pinpoint risks, prioritize mitigation measures, and guide strategic decision-making. Our risk-based approach fills a critical gap in biodiversity data and provides a scalable framework for aquaculture portfolio assessment. It supports businesses in gradually improving their biodiversity knowledge and aligning with CSRD requirements.
Further pilot studies are underway to refine the methodology, including the consideration of indicator weighting and cumulative scoring mechanisms. These advancements aim to drive meaningful improvements toward more sustainable aquaculture practices.

5.11.P-Th349 Integrated Approaches to Addressing Sustainability, Quality, and Safety in Seafood Supply Chains

Sandra Ceballos-Santos*, Alba Bala and Pere Fullana, Escola Superior de Comerc International (ESCI), Universitat Pompeu Fabra (UPF), Spain*
Food supply chains (FSCs) face critical challenges in quality, safety, and environmental impacts, often treated as isolated issues. This siloed approach has led to policy inconsistencies and inefficiencies. Emerging management models, such as the European Food Policy, are shifting toward integrated frameworks that link production and consumption patterns with environmental and quality outcomes, but their implementation is often constrained by data gaps and stakeholder misalignment. Additionally, fraud particularly in the seafood sector adds another layer of complexity, with an estimated 30% of seafood sold globally being misrepresented or mislabeled due to limited transparency.
This lack of reliability directly impacts decision-making in the HORECA (Hotel/Restaurant/Café) sector and retail channels, where prioritizing sustainable, non-overfished species is vital for driving a wide change. However, despite the proliferation of certifications and ecolabels aimed at guiding sustainable choices, consumer trust is undermined by ethical uncertainties and doubts about the credibility of these schemes. The incorporation of a life cycle thinking approach and the use of scientifically recognized methodologies such as Life Cycle Assessment (LCA) provide a more transparent and reliable framework, ensuring that sustainability claims are grounded in verifiable, science-based data and offering consumers greater confidence in their choices.
To address these challenges, the SMART-FOODPRINT project aims to develop a robust framework to evaluate sustainability, traceability, and safety across the seafood supply chain from sea to plate using a life cycle perspective. This research will involve stakeholders among FSC to incorporate real data from fish producers and restaurant purchasing patterns to calculate indicators and combine them into a nexus index representing the overall performance of the system in terms of environmental, social, and economic performance.
The findings will illustrate a pathway to overcome the challenges of FSCs and serve as a foundation for developing traceability and certification schemes applicable to other food systems. This integrated methodology holds the potential to advance regulatory management and foster trust in ecolabeling practices, contributing to a more sustainable and transparent food sector.

Disclaimer/Disclosure: This contribution is part of grant PID2022-137023OB-C32, funded by MCIN/AEI/10.13039/501100011033 and FSE+ .

5.11.P-Th350 Integrating Two New Biodiversity Impact Pathways Into Life Cycle Impact Assessment of Food Products

Yohan Lanier[1], *Aurore Wermeille*[2], *Anne Asselin*[2] *and Myriam Saade*[3], *(1)Sayari; Ecole Nationale des Ponts & Chaussees, France, (2)Sayari, France, (3)Centre national de la recherche scientifique (CNRS), France*

1. Background & purpose

Biodiversity's general state is alarming, and IPBES indicates that current species extinction global rate is at least 10 to 100 times higher than the average rate over the last 10 million years. Intensive agricultural practices, on which the global food system is based, are a direct factor in biodiversity collapse. Faced with this observation, several food transition scenarios have been developed, recommending that consumers be informed on food products' impacts, both on climate and biodiversity. Yet life cycle assessment, one of the chosen methods for this goal, does not capture most of biodiversity-related aspects. Extensive research has been published to bridge this gap, but few are actively implemented. This study aims to implement two new impact assessment pathways and apply them to a sample of food datasets to assess the relevance of the associated biodiversity loss drivers for food products impact assessment.

2. Methods

Chaudhary and Brooks (2018) method is implemented to better capture the variety of land use practices' intensity levels. Hélias et al. (2023) method is implemented to quantify impacts linked to natural biotic resource depletion. Those two new impact categories are integrated into the area of protection 'Ecosystem Quality' from LC-Impact which is evaluated on ten food products from Agribalyse database. Product samples represent a variety of protein rich products & include 3 meats, 3 fishing products, 1 aquaculture product, 1 egg and 2 legumes. Results are presented per kg of protein at consumer.

3. Results

Land use and natural biotic resource depletion explain 66% to 98% of impacts for nine of the ten food products. For wild fishes, impact is highly dependent on fish stocks and techniques while for meat, the usual hierarchy between red & white meat is observed. Regarding ranking between products, Thunnus thynnus from the Mediterranean Sea has the highest impact followed by ground beef. Legumine have the lowest impact alongside Thunnus albacares. Aquaculture shrimps show similar impacts to chicken and pork. Several limitations are identified and should be addressed in future work.

4. Conclusion

This study provides an insight on the contribution of land use and biotic resource depletion to food products' impacts on 'Ecosystem Quality'. Results suggest that these pathways can hardly be neglected and argue for a better integration of these aspects.

5.11.P-Th351 Environmental Footprint Method Aligned Product Category Rules for Food Products

Sanna Hietala, *Anniina Lehtila, Juha-Matti Katajajuuri, Kirsi Usva, Hanna Tuomisto and Frans SIlvenius, Natural Resources Institute Finland (Luke), Finland*

The European Commission s Environmental Footprint (EF) initiative and the Finnish LCAFoodPrint project aim to enhance reliability in communicating environmental footprints. To improve the coherence and comparability between assessment of all main food product categories, the project develops Food-LCA guidance based on the EF method, yet with some exceptions. The guidance specifies the EF method further for the agricultural sector related to global warming potential, water scarcity and eutrophication.

For land use and land use change (LULUC) emissions, the emissions from mineral and organic soils were more clearly distinguished compared with the EF method due to the significant role of organic soil emissions in Finland. Furthermore, the possibilities to utilize open-access country-specific LULUC data from national GHG inventories were improved. We do not support simultaneous calculation of LULUC emissions and Carbon Opportunity Cost due to potential double counting. For animal and crop modelling, the use of country-specific methods from the national GHG inventories was prioritized, providing that the calculation method and all needed parameters are open-access.

The use of good-quality primary activity data, as well as good-quality secondary data, was seen an important for reliable and harmonized LCA. The data quality requirements of the EF method were seen strict, but highly needed. Thus, the requirements of the EF method were adapted, but not relaxed, to be applicable for the large and heterogeneous product group of the Food-LCA guidance.

The use of the Circular Footprint Formula (CFF), as presented in the current EF version, was seen complex and even hindering the aim of harmonizing LCAs. The credits for incineration and substitution of virgin materials are seen as elements of consequential modelling that are not suitable for attributional LCA aiming to harmonized consumer communication. The credits on incineration also make the LCAs significantly more complex, and most likely will lead to double counting. Therefore, a more simplified assessment of wastes based on allocation is proposed in the guidance.

In the project, also a guidance on communication was developed.

The developed specifications of the Food-LCA guidance could be considered in the future revisions of the EF method. To allow improved comparability between larger product categories, it is seen important that the PCRs of at least similar product categories align in the future.

5.11.P-Th352 Comparing results for Life Cycle Assessment and Ecosystem Services - Exemplified by Dairy Production

Martin Seiringer[1], *Stefan Hortenhuber*[1], *Erich Tasser*[2] *and Werner Zollitsch*[1], *(1)BOKU University, Austria, (2)Eurac Research, Italy*

The sustainability of agriculture is becoming an increasing concern for the general public. In this context, Life Cycle Assessments (LCA) are gaining importance. At the same time, it is recognized that agricultural land provides multiple important functions and services. The relationship between LCA and Ecosystem Services is increasingly discussed in recent LCA literature. Therefore, we investigate the relationship between indicators of Life Cycle Impact Assessment (LCIA) and Ecosystem Services in the context of dairy production.
To this end, we performed an LCA for 89 dairy farms with a functional unit of 1 ha managed farmland. The indicators assessed are Global Warming Potential (GWP), Marine Eutrophication Potential (MEP), Terrestrial Acidification Potential (TAP), Fossil Resource Demand (FRD) and Land Use (LU). Simultaneously, we assessed ecosystem services provided by agricultural land managed by these farms. The ecosystem services selected for assessment include food production, drinking water potential, erosion prevention, plant biodiversity and recreation potential. Data were collected by an online survey, from the Integrated Administration and Control System (IACS), freely available GIS data, remote sensing, and literature.
Preliminary results indicate that LCIA indicators correlate strongly when assessed for the functional unit of 1 ha. Strong negative correlations are observed between drinking water potential and all LCIA indicators, as well as between TAP and FRD and plant biodiversity and recreation potential. Erosion control, on the other hand, correlates poorly with the selected indicators. Overall, these negative correlations paint a similar picture for both LCIA and ecosystem service indicators: High production intensity per ha in dairy production is associated with higher impacts and lower ecosystem services. To improve comparability, it is necessary to harmonise the system boundaries and functions of the production system under consideration. Harmonisation of these aspects between LCA and ecosystem services remains a challenge and needs further discussion.

Disclaimer/Disclosure: The authors would like to thank SalzburgMilch GmbH for the cooperation and funding of the research.

5.11.P-Th353 A Sustainable Transportation System Will Require Sustainable Dietary Patterns and Food Systems: Focus On Cycling Life-Cycle Impacts Including Additional Calories Intakes and Regional Diet Evolutions

Anne de Bortoli[1], *Susie Ruqun Wu*[2], *Viviane Blanc*[2], *Cecile Sophie Marie Bulle*[2] *and Catherine Houssard*[2], *(1)Polytechnique Montreal, Canada, (2)UQAM, Canada*

Increasing active mobility cycling, walking seems a promising lever to mitigate impacts to climate change, but switching to active modes requires to produce more food to supply additional calorie intakes (ACI). Accounting for more than 1/3 of the global land distance traveled by passengers, cycling also requires substantial extra calories, making its environmental impacts intrinsically linked to fo od system s sustainability. This study aims to explore (a) the life cycle impacts of different cycling practices by region and type of bike including ACIs, and (b) the share of cycling environmental impacts in prospective mobility scenarios under different archetypical regional diet evolutions.
The method is based on : (1) modeling scenarios of global future transportation demands for land passenger travel, (2) conducting the LCA of transportation modes, (3) assessing the environmental impacts of the scenarios. (1) is an extrapolation of the International Transportation Forum scenarios, where technologies by mobility mode are completed using other sources. In (2), we develop regional archetypes of conventional modes to conduct prospective LCAs using premise. We gather existing and develop new life cycle inventories of bikes (electric/mechanical (e-/m-), standard/sportive/cargo, aluminium/bamboo/carbon), model calories consumed depending on regional cycling practices

(speed/intensity) using the Metabolic Equivalent model, as well as different dietary patterns (vegetarian, keto, 6 average regional diets), to calculate the life cycle impacts of different cycling practices and transportation scenarios using IMPACT World+ (3).

Cycling environmental impacts change highly when considering ACI. The carbon footprint of cycling in Africa goes from 11 to 26 gCO2e/km, while at the other extreme, it jumps to 95 gCO2e/km in Europe. Under a keto diet, cycling with a m-bike emits 135 gCO2e/km, what is like using an e-car with a green electricity. Under highly emitting diets, e-bikes perform better, but e-biking or m-biking emits similarly under a vegetarian diet (35 g). Under stable diets and food systems but high decarbonization ambitions in the transportation sector, cycling would reach by mid-century 1/6 of the contributions of the global land transportation to CC and water scarcity, and 1/3 to its land occupation and marine eutrophication, mostly due to ACIs. Becoming all vegetarians mitigates some impacts but may make the contribution to water scarcity explode.

5.11.P-Th354 Replacing Meat and Dairy with Plant-Based Options in Spain Could Reduce Environmental Human Health Damage by a Third While Promoting More Nutritionally Adequate Diets

*Ujue Fresan[1], **Montserrat Nunez**[2], Ines Valls[3] and Ralph Rosenbaum[2], (1)ISGlobal, Spain, (2)IRTA, Spain, (3)ISEM, University de Montpellier, CNRS, IRD, Spain*

The shift from traditional plant-based Mediterranean diets to Western dietary patterns in Spain has exacerbated chronic diseases and increased environmental degradation. This study quantifies the human health burden linked to the environmental impacts of Spain's food demand, assessing the potential benefits of reducing meat and dairy consumption and food waste. Using the IMPACT World+ v2.0.1 Life Cycle Assessment (LCA) method, the environmental health impacts of food consumption and waste in Spain during 2022 were evaluated. Scenarios involving the reduction or replacement of meat and dairy with plant-based options and the mitigation of food waste were analyzed for environmental human health and nutritional outcomes. The ReCiPe 2016 v1.1 method was used for sensitivity analysis. Meat, fish, and dairy contributed 56% of dietary environmental human health damage, with total food demand resulting in 228,156 DALYs. Replacing 100% of meat and dairy with plant-based alternatives could reduce this burden by 32.4%, while eliminating food waste could lower it by 4.6%. Combined interventions may prevent 37% of DALYs. Nutritional analyses demonstrated that these dietary changes would result in diets more closely aligned with WHO guidelines, promoting improved adherence to recommended nutrient intakes. Transitioning towards plant-based diets and reducing food waste can significantly decrease environmental human health damages while fostering healthier, sustainable dietary practices in Spain. Policymakers should integrate these strategies into public health initiatives to mitigate climate and health crises.

5.11.P-Th355 Life Cycle Assessment of an Innovative Agrivoltaic Apple System and Comparison with Conventional Apple Production

***Theresa Krexner**[1], Alexander Bauer[2] and Iris Kral[3], (1)BOKU University, Austria, (2)BOKU University, Italy, (3)EY Denkstatt, Austria*

The cultivation of apples represents a highly relevant agricultural sub-sector in Austria. Nonetheless, a number of challenges currently exist, including rising temperatures and extreme weather events resulting from climate change, which can lead to lower yields and poor quality. Additionally, new pests and diseases have emerged due to altered production conditions alongside economic considerations, including fluctuating market prices and intensifying market competition. One potential solution to protect apples against extreme weather conditions, potentially decrease pesticide use and also to provide additional income in form of sold electricity, is the combination with electricity production by stilted PV modules: agrivoltaics. In this study, an apple agrivoltaic system in Lower Austria is assessed using the Life Cycle Assessment method to evaluate potential environmental impacts and compare them with the current status quo of conventional apple production. A cradle-to-gate Life Cycle Assessment is conducted based on primary plant data for both the innovative and the conventional apple production. As the agrivoltaic system under study is a multi-output system, it is necessary to consider how the multi-outputs should be dealt with. In order to comply with the allocation hierarchy, set out in ISO 14044 and to facilitate the communication of the results to a broad audience, inputs and outputs are divided between the two outputs apples and electricity. In the case of inputs such as the mounting structure of PV modules, the division is based on the wood pillars for hail nets in conventional production. The functional unit is set to 1 kg of apples and 1 kWh of electricity. The most important impact categories, including climate change, eutrophication, acidification and toxicity, will be assessed using ReCiPe Midpoint 2016 impact assessment method. The software openLCA v2.1.1 with Ecoinvent database 3.10 will be used. The overall aim of this work is to evaluate the advantages of this innovative apple production system compared to a conventional production.

Disclaimer/Disclosure: This project is funded by the Federal Ministry of Agriculture, Forestry, Regions and Water Management via dafne.at. The BML supports applied, problem-oriented research in its area of expertise.

5.11.P-Th356 Environmental Sustainability of Diets for Fish and Poultry Production and Links With Animal Health

*Sara Silva[1], Joana Oliveira[2], Ricardo Assuncao[2] and **Paula Quinteiro**[1], (1) University of Aveiro, Portugal, (2) Egas Moniz School of Health & Science, Portugal*

The growing global population has increased the demand for fish and poultry products, species valued for short production cycles, and high feed efficiency. The Life Cycle Assessment (LCA) methodology has been applied to quantify the environmental impact of fish and poultry production systems, identifying feed production as the primary contributor to global warming impacts. This approach supports adopting sustainable animal feeding practices to mitigate these environmental effects. This includes improving the feed efficiency of the animals and incorporating alternative and locally produced feed ingredients (e.g., insect-based products, algae, etc) into diets. Ensuring the environmental sustainability of fish and poultry production through animal diets requires meeting the animals' nutritional needs and reducing their environmental processing impact while supporting their health and welfare. This review aims to assess the environmental performance of diets in fish and poultry production based on LCA while also examining their connection to animals' health impacts. For this purpose, articles published in peer-reviewed journals focusing on LCA of diets for fish and poultry were considered. The final sample encompasses 56 case studies and 4 reviews. Different involved scenarios were identified within case studies as 103 occurrences, corresponding to 78 LCA and 25 nutritional adequacies for the animals. This work shows that LCA methodological choices varied among the case studies, namely in selecting the functional unit, system boundaries, and multifunctionality. Global warming (measured in kg CO2 eq.) is the most frequently assessed impact assessment category. Notably, crop production (e.g. soybean) and fishery by-products were identified as major contributors to the overall environmental impact of feed production. Regarding animal health impacts, the diet formulations analysed were generally comparable to reference diets and aligned with established dietary requirements. Further investigation is needed to advance toward a holistic approach, recognizing the interconnectedness of animal and human health, while ensuring sustainability. This holistic perspective should prioritize food security, promote sustainable resource use, and support a circular economy.

5.11.P-Th357 Framework to Conduct a Life Cycle Sustainability Assessment for Insect-Derived Products

*Sara Silva[1], Ana Rita Marques Fonseca[1], Fernando Ramos[1], Marta Ferreira Dias[1], Mario Martin-Gamboa[2], Rui A. dos Reis[3], Daniel Alexandre Bruno[1], Emanuel Lourenco[3], **Ana Cláudia Dias**[1] and Paula Quinteiro[1], (1)University of Aveiro, Portugal, (2) Rey Juan Carlos University, Spain, (3)INEGI Institute of Science and Innovation in Mechanical and Industrial Engineering, Portugal*

The increasing demand for sustainable food and feed products has driven the agri-food and livestock industries to seek innovative alternatives, with insect-derived products emerging as promising nutritional sources that support circularity. To comprehensively assess the sustainability of these products, a Life Cycle Sustainability Assessment (LCSA) framework was developed, defining methodological choices for environmental, social, and economic assessments. This latter component replaces the traditional life cycle costing analysis that focus on costs. Integrating an economic assessment, both costs and economic impacts through the supply chain are encompassed in LCSA. The Life Cycle Assessment (LCA) is grounded on the Environmental Footprint (EF) guidance, while the Social Life Cycle Assessment (S-LCA) follows UNEP/SETAC guidelines. The proposed framework promotes the harmonization of shared elements

across the four interrelated phases of the life cycle structure for the three methodologies, supporting stakeholders in the agri-food industry in informed decision-making. No specific recommendations for insect production or insect-derived products exist. Therefore, for the LCA, it was recommended to assess the sixteen impact indicators and select the more relevant ones following the EF guidelines. In the S-LCA and economic assessments, the amount of existing impact indicators combined with limitations in data availability creates challenges in assessing all of them. In this sense, a procedure for selecting impact indicators has been developed, to ensure that the perspectives of relevant stakeholders -workers, local community, society, consumers, and value chain actors- are considered. Moreover, the impact assessment methods selected are the Reference Scale approach for S-LCA and the monetary valuation for economic assessment. This framework also describes how to identify environmental, social, and economic hotspots. Future research should focus on the validation of these methodological approaches, to enhance the framework s applicability as the insect industry continues to grow.

5.11.P-Th358 Insect Frass as a Sustainable Alternative to Conventional Fertilizers: Enhancing Soil Health and Agricultural Productivity

*Ines Bento Cruz, Jose Nereu Pinto, Ana Rita R. Silva, Amid Mostafaie, Catarina Correia de Lemos Malheiro, Diogo Filipe Nunes Cardoso, Susana Loureiro, **Ana Eduardo Rodrigues**, Pedro Monteiro and Gloria Pinho, University of Aveiro, Portugal*

The increasing need for sustainable food production has driven research into novel organic fertilizers, such as insect frass, an entomofertilizer resultant of insect farming. This study explores the use of frass from Hermetia illucens (black soldier fly) larvae as an alternative to conventional synthetic mineral fertilizers, NPK (nitrogen, phosphorus, potassium), associated with nutrient hotspots and eutrophication events. Two different frasses were used: 1) frass obtained from insect digestion of cereal waste and 2) olive-pomace frass, an entomofertilizer resulting from the bioconversion of olive pomace, a residue of the olive oil industry. The aim of this study was to assess the potential of both entomofertilizers to replace or complement mineral fertilizers in agriculture at a laboratory scale. In addition to the control group, which consisted of natural LUFA 2.2. soil with no added fertilizer, the treatment groups included both mineral fertilizer and each type of frass at relevant rates, and different rations between NPK and frass application. Plant performance endpoints were assessed (germination, biomass, photosynthetic activity and productivity) in two full life cycle plant pot tests with Brassica rapa, following the ISO 22030 guideline. In the first cycle, all fertilization regimes were applied to the soil. For the second full life cycle plant test, the soil that remained after harvesting was used without further amendment. Soil function was assessed by measuring soil enzyme activities (urease, ?-glucosidase, aryl sulfatase, dehydrogenase, and phosphatases) at the end of each cycle. Additionally, to evaluate the safety of all used fertilization regimes, ecotoxicological assays were performed using two soil model invertebrates, Enchytraeus crypticus and Folsomia candida, following the OECD-220 and OECD-232 guidelines, respectively. Results showed that all fertilization regimes increased significantly plant performance endpoints. Frass induced soil enzymatic activity, especially at the end of the second plant cycle. This reveals a long-term positive influence on soil biochemical processes and nutrient cycling. Survival and reproduction of F. candida were not affected, while reproduction of E. crypticus increased significantly with organic fertilization. This study highlights the efficacy and safety of insect frass as a promising solution for sustainable agricultural practices.

5.11.P-Th359 Life Cycle Assessment of Insect-Derived Frass: Perspectives from a Literature Review

***Ana Rita Marques Fonseca**, Paula Quinteiro and Ana Cláudia Dias, University of Aveiro, Portugal*

One conceivable approach towards sustainable development and circular business models within the agri-food industry is using insects to convert biomass into alternative protein sources. Besides protein, insect production also generates frass, composed of insect excrement, exuviae, and leftover feedstock, viewed as a valuable product that holds potential in the fertiliser sector, due to its nutrient content. Life cycle assessment (LCA) can be applied to identify the environmental benefits and drawbacks of insect-derived

products, including frass. However, this can be challenging from several perspectives (e.g. multifunctionality) and, so far, no harmonised method is available.
This study aimed to conduct a literature review using Scopus and Web of Science to assess LCA studies that include frass production and/or application. The search was performed using combinations of keywords and their abbreviations, including: life cycle assessment OR carbon footprint combined with frass OR insect AND fertiliser OR compost . A total of 17 studies were analysed, focusing on aspects such as the goal, system boundaries, and multifunctionality.
The goal of the studies spanned from assessing insect-derived products (primarily focused on protein) or comparing waste management technologies. While system boundaries exclude the use stage in most studies, some include frass application, with varying assumptions on emissions. Most studies consider that frass substitutes fertilisers based on the respective nutrient content (considering one or more nutrients), assuming equal nutrient bioavailability regardless of the fertiliser considered. However, some studies are unclear on the assumptions for fertilizer substitution. For example, the avoided fertilizer type is not identified.
In conclusion, increasing the transparency of the studies is recommended, as well as harmonising the methodological choices to guarantee study comparability. Future research should consider findings from interdisciplinary research (e.g. soil science) to improve the quality of the assumptions and overall impact assessment.

5.11.P-Th360 Toxicokinetics of Polycyclic Aromatic Hydrocarbons (PAHs) Accumulation in Hermetia illucens

*Amid Mostafaie[1], Patrícia Veríssimo Silva[1], Marija Prodana[1], Ana Rita R. Silva[1], Jose Nereu Pinto[1], Regina M. B. O. Duarte[1], Iva Guidini Lopes[2], Bryan W. Brooks[3], Susana Loureiro[1] and **Diogo Filipe Nunes Cardoso**[1], (1)University of Aveiro, Portugal, (2) Swedish University of Agricultural Sciences, Sweden, (3) Baylor University, United States*

Entomoculture industries widely use Hermetia illucens larvae due to their exceptional ability to consume a wide variety of organic matter. Also, the European Commission approved the consumption of H. illucens for animal feed in 2017. Therefore, the role of H. illucens in waste management and protein production raises concerns about introducing contaminants from waste sources into the food supply chain. The presence of polycyclic aromatic hydrocarbons (PAHs), known as oncogenic substances, in animal feed remains unregulated despite their restriction to human consumption. Considering the need to understand how and up to what extent PAHs accumulate in edible insects, this study aims to fill this gap in scientific knowledge. For that, a two-phase bioaccumulation assay with toxicokinetic modelling was conducted using four different PAHs (benzo(a)pyrene, Benz (a)anthracene, benzo(b)fluoranthene, and chrysene) given to insects in the substrate (Gainesville (GV) diet, consisting of 50% wheat bran, 30% alfalfa, and 20% corn meal). The experiment was divided into two phases: 5 days of exposure to the contaminated substrate in the concentration of 12.5 µg kg-1 for each PAH, according to the EU limitations for undesirable substances in food - ?4PAH 50 µg kg-1. The subsequent phase was transferring the organisms into the non-contaminated substrate for 5 days. During the experiment, five replicates of organisms were sampled each day, and the concentration of PAHs in insect bodies was measured. The Akaike Information criteria (AIC and AICc) identified the one-compartment first-order model with an inert fraction (FI model) as the optimal model for fitting our bioaccumulation data. The modelling identified the constant uptake rate, constant elimination rate, half-life of the contaminant, and the inert fraction. Accumulation occured in chrysene, benz(a)anthracene, and benzo(b)fluoranthene, but the only PAH that we were able to apply toxicokinetc modelling was benz(a)anthracene. However, the concentration of PAHs in insects was higher than the EU limitation on the last day of exposure to the contaminated substrate. On the other hand, the half-life of the contaminant was less than one day, expressing the ability of organisms to eliminate the contaminant. These findings underscore the importance of a depuration phase in entomoculture industries, particularly when they utilize agricultural, agro-industrial, and other organic waste streams for insect production.

5.11.P-Th361 Crickets and Metals: Uptake and Elimination of Four Metals in the House Cricket Acheta domesticus

***Jose Nereu Pinto**, Ana Rita R. Silva, Rui G. Morgado, Ana Eduardo Rodrigues, Patrícia Veríssimo Silva, Susana Loureiro and Diogo Filipe Nunes Cardoso, University of Aveiro, Portugal*

Among the four legal insect species for human consumption in the EU, the house cricket Acheta domesticus is the second most studied, primarily under ecological perspectives rather than food safety. A. domesticus, like other insects, can be reared on various unused organic matter, promoting a circular, sustainable economic model. Regardless, ensuring food safety is critical, and there is still a wide knowledge gap in the transfer and accumulation of contaminants from substrates to A. domesticus. With that in mind, this study aimed to evaluate the uptake and elimination of four metals considered of concern: arsenic (As), cadmium (Cd), lead (Pb), and mercury (Hg) by A. domesticus nymphs, using a toxicokinetic approach.

The study included a ten-day uptake phase, where 10-day old nymphs were fed metal-spiked chicken feed, followed by a ten-day elimination phase with clean feed. Metals were introduced as HgCl?, CdCl?, NaAsO?, and Pb(NO?)? at regulatory benchmark concentrations for feed (0.1 mg/kg Hg, 2 mg/kg Cd and As, 10 mg/kg Pb, dry weight). Control groups were fed with clean food only in both phases of the test. Conditions included a 16h/8h light/dark cycle at 28±1°C. Samples were collected every other day, lyophilized, and analyzed for metal content by inductively coupled plasma mass spectrometry.

Our results demonstrated that the accumulation of metals in A. domesticus is dependent on the specific metal. Importantly, none of the four tested metals exceeded the regulatory threshold limits for feed in the EU, with Cd having the highest bioaccumulation factor (BAF = 0.864) and Hg the lowest (BAF = 0.003). Furthermore, organisms eliminated most accumulated metals within the first twenty-four hours after exchanging contaminated for clean food, underscoring the safety of using these organisms as food and feed sources. Results indicate that A. domesticus accumulates metals as expected, however, to a much lesser extent than other previously tested insect species (e.g., Tenebrio molitor and Hermetia illucens). This study supports Acheta domesticus as a sustainable bio converter, specifically for biomass containing trace metals. Notwithstanding, it is crucial to continue expanding the scope of studies with these organisms since, as far as we know, bioaccumulation and toxicokinetic studies with other contaminants are either limited or nonexistent.

5.11.P-Th362 Understanding Contaminant Safety Across Edible Insect Species: A Step Toward Sustainable Food Systems

***Diogo Filipe Nunes Cardoso**[1], Ana Rita R. Silva[1], Amid Mostafaie[1], Iva Guidini Lopes[2], Jose Nereu Pinto[1], Marija Prodana[1], Patrícia Veríssimo Silva[1], Paula Alvito[3], Rui G. Morgado[1], Bryan W. Brooks[4] and Susana Loureiro[1], (1) University of Aveiro, Portugal, (2)Swedish University of Agricultural Sciences, Sweden, (3)National Health Institute Dr. Ricardo Jorge (INSA), Portugal, (4) Baylor University, United States*

Edible insects are a promising solution to meet global protein demands sustainably. However, concerns about contaminants like metals, PAHs, and mycotoxins in insect biomass raise critical questions for food safety. Ensuring the safety of insect-based foods is essential to gaining consumer trust and shaping clear regulatory frameworks. This study investigated how contaminants behave across Tenebrio molitor (mealworms), Hermetia illucens (black soldier fly), and Acheta domesticus (house crickets). Insects were reared on substrates with controlled contaminant levels (aligned with EU maximums for feed), assessing bioaccumulation and its implications for human and animal consumption. Two-phase bioaccumulation assays and toxicokinetic modelling were performed to estimate uptake and elimination rates, bioaccumulation factors, and contaminant residence times. This approach provided valuable insights into how contaminants are retained and eliminated in insect tissues, addressing a significant knowledge gap. Results showed species-specific differences in metal accumulation (As, Cd, Pb, Hg). Crickets exhibited the lowest accumulation, Black soldier flies the highest, and mealworms the intermediate. PAHs accumulated less than metals, but notable trends appeared in mealworms and black soldier flies. Elimination rates were rapid for most contaminants, with near-complete elimination within one day. A critical exception was cadmium in black soldier flies, which showed prolonged retention, raising safety concerns and attention to a need for a prolonged elimination period. Exposure to the maximum allowed feed contaminant levels revealed that, in some cases, insects require short depuration periods to ensure their safe use as feed. PAHs, which are not currently regulated in feed, showed potential for accumulation, emphasizing the need for further research given their importance in food safety legislation. This work highlights the need for species-specific safety assessments and tailored farming practices to minimize risks. Within this work, we provide data for developing robust safety guidelines by addressing these challenges. Our findings contribute to integrating edible insects into sustainable food systems while ensuring their safety and nutritional value for consumers worldwide.

D. Cardoso is hired under the Scientific Employment Stimulus - Individual Call (CEECIND/01190/2018).

5.11.P-Th363 Chemicals of Concern in Food Packaging: A Matter of Sustainability

*Birgit Geueke, Justin Michael Boucher, Etienne Cabane, Lindsey V. Parkinson, Helene Wiesinger and **Jane Muncke**, Food Packaging Forum, Switzerland*

In a globalized system, food is increasingly processed and transported over long distances. This is enabled by highly functional food packaging. However, food packaging is also a driver of long-term damage to the environment and human health. From the sourcing of raw materials over production to end-of-life, food packaging has multiple impacts on the use of resources, environmental pollution, and exposure to chemicals. Therefore, decision makers in the food sector need transparent and science-based information to choose safe and sustainable food packaging for each type of food.

The UP Scorecard was developed for this purpose and is built on a scoring system, including the six impact areas climate change, water use, plastic pollution, sustainable sourcing, recoverability, and chemicals of concern. While other packaging assessment tools are available, they often focus on a single impact area, such as climate change, but usually omit the chemical safety of a material.

To assess chemicals of concern within the UP Scorecard, we applied a hazard scoring system to over 14,000 known food contact chemicals (FCCs), based on the methodology described in the PlastChem report (DOI: 10.5281/zenodo.10701706). We focused on the human health hazards only, as there is direct oral human exposure from the many chemicals that migrate from packaging into foodstuffs. In total, we found 4680 FCCs with hazard scores indicating different levels of concern for human health. 419, 121, and 406 out of these FCCs have the highest hazard score for carcinogenicity, mutagenicity and reproductive toxicity, respectively, whereas 45 FCCs are confirmed endocrine disrupting chemicals, and 1330 FCCs have specific organ toxicity.

To facilitate access to this information for decision-makers, such as procurement professionals, we grouped the chemicals of concern based on their structural properties but also integrated filtering options regarding the use and presence of FCCs in food contact materials. This will help to identify, screen and avoid the most hazardous chemicals for each food packaging material and support development of safe and sustainable food packaging solutions.

5.11.P-Th364 Exposure to Micro- and Nanoplastics: Is Food Packaging a Source?

*Lisa Zimmermann[1], Birgit Geueke[1], Lindsey V. Parkinson[1], Christoph Schuer[2], Martin Wagner[3] and **Jane Muncke**[1], (1)Food Packaging Forum, Switzerland, (2)Eawag, Swiss Federal Institute of Aquatic Science and Technology, Switzerland, (3) Norwegian University of Science and Technology (NTNU), Norway*

Micro- and nanoplastics (MNP) have been detected in a variety of foods and beverages, and concerns for MNP impacts on human health exist. Environmental contamination has been identified as one exposure source of MNPs to foodstuffs. However, the role of plastic food packaging or other plastic food contact articles (FCA) has received less attention despite plastics being ubiquitously used in the food system.

Therefore, we systematically mapped the scientific evidence of MNPs present in foodstuffs and originating from FCAs during normal and intended use. We searched several public databases for relevant studies, and, from the eligible ones, we extracted a wide range of data pertaining to experimental design, FCA type, MNPs properties, and the food type or food simulant. In addition, we critically appraised the included studies regarding general data quality, material identification methods, polymer type reporting, and study design, using a newly developed method. The extracted data can be accessed through a publicly available dashboard

We identified 104 studies matching our eligibility criteria. From these sources, we extracted data and generated 601 database entries. The most studied FCAs are bottles (31% of all entries), containers (19%), tea bags (12%), cups (10%) and bags (10%). A total of 212, 121, and 257 entries refer to the analysis of MNPs in liquid and solid foodstuffs as well as food simulants, respectively. While the included data suggest widespread contamination of MNPs in food over 90% of entries reported an MNP presence most studies are of low quality. Using our critical appraisal, we found only seven studies to be highly reliable. These studies demonstrate that under intended or foreseeable conditions of use, plastic FCAs can release MNPs into foodstuffs. Importantly, our reliability assessment also emphasizes that a harmonized approach to testing and reporting MNP migration from FCAs into food is needed to improve data quality and reporting, and to ultimately introduce mitigation measures for reducing human exposure to MNPs.

Given the current knowledge gaps, further research to characterize material- and use-dependent MNP migration. Furthermore, we propose the inclusion of MNP migration testing in regulatory frameworks for FCAs as one measure to reduce MNP exposure via food ingestion. This is especially relevant since foods are increasingly (ultra-)processed, and due to processing, the foods contact with plastics is also increasing.

5.11.P-Th365 Circularity in the Food System: Exploring the Sustainability of Alternative Uses of Whey Side Streams

John Daniel Hader, *Nadia Ilaria Malinverno and Claudia Som, EMPA - Swiss Federal Laboratories for Materials Science and Technology, Switzerland*

Roughly one third of food produced is wasted, either at the production, processing, or consumer level. One important subset of food waste is protein-rich side streams from industrial food processing, such as whey from cheese production. Whey contains proteins (e.g., beta-lactoglobulin) which have unique properties that are currently explored for valorization into advanced materials such as bioplastics and CO2 capture material. The aim of this study is to assess the potential benefits and environmental impact of diverting whey from traditional uses (i.e., as animal feed) to select emerging alternative uses currently at or near the lab-scale level, namely in bioplastics for food packaging, CO2 capture material, and wastewater treatment material. We conduct a first-order assessment assuming all whey in Switzerland (1.3E+6 tons wet weight) is diverted to one of each of these three alternative uses, estimate the total mass of whey protein-based materials that could be produced based on literature-derived conversion factors, and assess the possible uses of these materials. The potential amount of bioplastic film derived from whey would be 7 times the total Swiss demand for food film packaging, the potential mass of CO2 capture material could capture 21% of annual Swiss CO2 emissions, and the potential amount of wastewater treatment membrane could absorb roughly 7500 times the amount of ibuprofen present in Swiss wastewater (note this assumes extrapolating lab-scale efficiencies of the materials to real-world operation). We select the CO2 capture material for additional investigation in a refined Swiss whey usage scenario, due to the importance of advancing carbon-capture technology in the near future. We construct two alternative whey usage scenarios: 1.) The Swiss whey currently utilized for low-grade animal feed (5.87E+5 tons) is diverted to produce CO2 capture material, with this low-grade feed whey being replaced by a plant-based feed, and 2.) All Swiss whey used for animal feed (low- and high-grade, 9.84E+5 tons) is diverted for use in CO2 capture material, while a nutritionally-equivalent mass of plant-based protein replaces the animal meat for human consumption that resulted from the whey feed. Ecoinvent will be used to assess environmental effects resulting from the baseline and alternative whey usage scenarios. This study provides a preliminary framework for informing large-scale decision making around the more circular use of food waste side streams.

5.11.P-Th366 Upcycling Agricultural and Industrial Side-Flows for Food Development: A Risk Assessment Approach

Emma Momberg[1], Elvira Molin[1], Johan Hulten[1], Anneli Julander[1], Veronica Ohrvik[2], Ingrid Strid[3] and ***Georgios Giovanoulis[1]***, *(1)Swedish Environmental Research Institute (IVL), Sweden, (2)Axfoundation, Sweden, (3)SLU - Swedish University of Agricultural Sciences, Sweden*

Food waste and losses along the supply chain represent critical challenges to sustainability on global and national scales. Up to one-third of all food produced globally is wasted, leading to reduced producer profitability, diminished food security, and significant environmental degradation. In Sweden, primary production and food industries face substantial losses of raw materials, as identified by the Swedish Board of Agriculture. Approximately half of slaughterhouse by-products and a third of carrots intended for human consumption are diverted to alternative uses such as biogas production or animal feed, rather than direct food applications. Tackling these losses aligns with the goals of the Swedish Food Strategy, which prioritizes resource efficiency, profitability, self-sufficiency, and environmental sustainability. Utilizing by-products for novel food development, however, is hindered by concerns regarding potential contamination. Environmental contaminants such as dioxins, furans, PCBs, PAHs, PFAS, plasticizers, pesticides, pharmaceuticals, and trace elements can enter the food chain posing risks to human health and complicate regulatory compliance, emphasizing the need for robust chemical analysis and risk assessment. This study explores upcycling opportunities for agricultural and industrial side-streams in Sweden, focusing on both plant-based and animal by-products. Through literature reviews and stakeholder workshops, we identified promising candidates for chemical analysis and food development, including pig and beef blood, beef kidneys, carrots, and apple press residues. Chemical analyses were conducted to assess the above-mentioned contaminants, following rigorous protocols with microwave extraction, ICPMS, LC or GC-MS/MS, suspect and target analyses. Nutritional profiling revealed that these by-products are nutrient rich, with high protein, vitamin, and mineral content making them viable for food innovation. Our findings highlight the dual potential of these side-streams to reduce food waste and develop sustainable, high-value food products. The study underscores the importance of integrating risk assessment into food innovation to ensure safety, enhance market acceptance, and support circular economy objectives, while also contributing to addressing critical sustainability issues by converting underutilized resources into nutritious and safe food alternatives, fostering resilience within food systems while mitigating environmental impacts.

Disclaimer/Disclosure: The authors thank the Swedish Research Council FORMAS for funding this project within the national research program for food, grant number 2022-01946.

5.11.P-Th367 RNAi: A Targeted Pesticide Technology for a More Sustainable Agricultural System

Laurent Mezin, *GreenLight Biosciences, United States*

The global use of pesticides in agriculture and other use sites is not sustainable. Conventional pesticides affect not only the target pests but also non-target organisms, potentially decreasing biodiversity on- and off-field. The pesticides and their residues can have a detrimental effect on human health and the environment, sometimes for years after application. New technologies are needed to ensure a safer and more sustainable global food system. RNA interference (RNAi) is one such technology. This technology uses double stranded RNA as an active substance (AS) to interfere with the production of a protein in the target pest and can be designed to be very specific to a single target pest, with little to no effect on humans or non-target organisms. New pesticide AS can be rapidly designed using bioinformatics to ensure the mode of action is specific to the target pest and to avoid any likelihood of toxicity to humans or any non-target organisms. These AS are effective at low application rates, minimizing the quantity of chemicals (including other formulants) applied to a field and reducing the use of old chemistries. They are also compatible with current agricultural practices. Multiple studies have shown they have no toxicity in humans, low to no toxicity to non-target organisms, and preserve biodiversity even on the treated field. The AS degrades rapidly in the environment to naturally ubiquitous nucleotides. New AS that use RNAi are registered or pending registration in the US, Europe and other countries. From the inputs into the manufacturing process to the low application rates in the field, RNAi pesticides can reduce greenhouse gas emissions substantially, compared to conventional petrochemical-derived pesticides. RNAi pesticides have the potential to increase worker safety, support biodiversity, replace older chemistries, and reduce greenhouse gas emissions related to agriculture without placing any additional burden on the grower or farmer. Thus RNAi technology as a crop protection tool can support sustainable agriculture.

Track 6. Environmental Policy, Risk Management, and Science Communication

6.01.P Exploring Earth System Boundaries and Staying within Those Boundaries for Chemical Pollutants

6.01.P-Mo449 Moving Forward with Safe and Just Earth System Boundaries for Chemical Pollutants

Miriam L. Diamond[1], *Zhanyun Wang*[2] *and Anna Shalin*[1], *(1)University of Toronto, Canada, (2)EMPA - Swiss Federal Laboratories for Materials Science and Technology, Switzerland*

The planetary boundaries concept, first introduced by Rockström et al. in 2009, has effectively communicated the dire impacts of society s actions on the biophysical systems of the Earth. The key point of the boundaries concept is that these exceedances are pushing the Earth s biophysical systems outside of safe Holocene-like conditions upon which human society is predicated. In 2009, evidence showed an exceedance of 3 of 9 boundaries; the most recent assessment indicates that several more boundaries are exceeded. The need for a boundary for chemical pollution, or more recently known as novel entities , has been recognized but has remained challenging to quantify because of the complexity of the domain the number of chemicals and the number of impacts, among other challenges.
In 2021, Rockström, Gupta et al. extended the planetary boundaries concept to define safe Earth system boundaries according to the safe operating space for the Earth s biophysical conditions. To this they added just Earth system boundaries that explicitly address the inequitable impacts experienced by populations, notably humanity, today and for future generations. These boundaries consider global and regional

impacts to acknowledge the wide geographic variability in the severity of effects. Thus, a global boundary can be (and is) exceeded as a result of overshooting multiple regional boundaries. Importantly, this effort, under the Earth Commission 2.0, strives to build transformative pathways that will move society from current, unsustainable trajectory to new, more safe and just conditions.
Applying the Earth system boundary concept to chemical pollution continues to be a challenge. Here we present our approach for exploring safe and just Earth system boundaries for chemical pollution and charting alternative sustainable futures through transformative pathways. The approach includes three pillars. First, data mining will be conducted to scan the horizon for existing and emerging issues to avoid looking under the lamppost and to identify future trends of chemical pollution. Second, we will investigate data-rich case studies to probe exceedances of safe and just boundaries. Finally, we will develop future transformative pathway scenarios, taking into account social, economic, technological and political dynamics and interactions, that could be implemented to move society towards a sustainable future.

Disclaimer/Disclosure: The authors thank The Earth Commission, which is hosted by Future Earth, for productive discussions and funding.

6.01.P-Mo450 Outside the Safe Operating Space of a New Planetary Boundary for PFAS: An Update

***Ian Cousins*[1]** *and Martin Scheringer[2], (1)Stockholm University, Sweden, (2)ETH Zurich, Switzerland*
It was recently proposed that, as with planetary boundaries, safe Earth system boundaries (ESBs) should define limits for maintaining a stable and resilient Earth system, whereas just ESBs should define limits to minimize harm to humans, including harm to human health and meeting minimum access to needs for today s and future generations. In a previous paper, we hypothesized that environmental contamination by per- and polyfluoroalkyl substances (PFAS) defines a separate planetary boundary and that this boundary has been exceeded. With the separation of planetary boundaries into just and safe ESBs, we would now conclude that a just ESB for PFAS has been exceeded. In this presentation, we will revisit the previous conclusions of our paper in light of new information on safe exposure limits for PFAS. We will also consider if this methodology can be applied to other contaminants. Recently, the United States Environmental Protection Agency (US EPA) set the Maximum Contaminant Level Goal (MCLG) for perfluorooctanoic acid (PFOA) and perfluorooctane sulfonate (PFOS) to zero due to the evidence that these substances cause cancer. The finding that these two PFAS have no safe level strengthens our previous conclusion that a just ESB for PFAS has been exceeded. We argue that the combination of high persistence and a no threshold toxicity has led to a number of substances already breaching a just ESB in addition to PFAS. For example, there several substances which have an MCLG set to zero by the US EPA and are known to be globally spread. In addition to PFOS and PFOA, those substances are: chlordane, 2,3,7,8-tetrachlorodibenozo-p-dioxin, heptachlor, heptachlor epoxide, hexachlorobenzene, polychlorinated biphenyls (individual PCBs and Arochlor mixtures) and toxaphene. These substances are generally captured under chemical legislation such as REACH or the Stockholm Convention. However, substances with high persistence and high long-range transport potential, but relatively low toxicity and/or low bioaccumulation potential have historically been considered of relatively low concern and are not captured by chemical regulations. For example, novel entities which are globally spread and have a poor reversibility (both due to high persistence) such as plastics and trifluoroacetic acid (TFA) have also been suggested as threats to ESBs. We conclude that a more precautionary regulatory approach based on high persistence alone is warranted to prevent future problems.

Disclaimer/Disclosure: Ian T. Cousins acknowledges funding from the European Union s Horizon 2020 research and innovation program project ZeroPM, under grant agreement No 101036756.

6.01.P-Mo451 The Global Threat from the Irreversible Accumulation of Trifluoroacetic Acid (TFA)

Andrea Gredelj[1], ***Hans Peter H. Arp*[2]***, Juliane Gluge[3], Martin Scheringer[4] and Ian Cousins[5], (1)Norwegian Geotechnical Institute (NGI), Norway, (2)Norwegian Geotechnical Institute (NGI); Norwegian University of Science and Technology (NTNU), Norway, (3) ETH Zurich, Switzerland, (4) ETH Zurich; Masaryk University, Switzerland, (5) Stockholm University, Sweden*
Trifluoroacetic acid (TFA) belongs to the subclass of per- and polyfluoroalkyl substances (PFAS) known as ultra-short chain perfluoroalkyl acids (PFAAs). Due to its extreme persistence and high mobility, TFA is widely detected in various environmental matrices, from precipitation, surface, ground and drinking water to plants and plant-based foods and beverages, soils and human blood serum. Currently, TFA concentrations are often much higher than those of other PFAS. TFA s omnipresence in the environment is due to various uses and emissions pathways from its use in chemical production to being a terminal

degradation product of chemicals containing the C?CF3 moiety and lack of a natural elimination process. Although TFA concentrations will inevitably increase in the future, what remains less clear is the planetary thresholds for which this accumulation may cause irreversible, ecological harm. Eco(toxicity) data is scarce and most no risk conclusions were based on aquatic studies that are nearly two decades old, without accounting for high environmental increases in TFA concentrations, unusual environmental behaviour and new scientific evidence. In this work, we analysed the scientific literature on TFA to assess if there is evidence of its exceedance of the planetary boundary thresholds as defined with three conditions set by Persson et al. Our analysis of peer-reviewed monitoring literature revealed over an order of magnitude increase in TFA concentrations across various environmental compartments post-2010, with studies expanding from a focus on atmospheric media to include new exposure media such as plant-based beverages, crops, dust, human serum, locusts, tree species, and drinking water. This growing presence of TFA raises concerns about potential disruptive effects on human health and Earth system processes that remain poorly understood, highlighting the need to address these gaps to assess whether TFA represents a planetary boundary threat. To investigate this, we examined both known environmental and health thresholds from regulatory sources and the potential effects reported in the literature that fall outside established toxicity assessment frameworks. The case of TFA being a planetary boundary threat will be presented, based on TFA s 1) increasing planetary exposure, which is 2) irreversible and accumulating due to emissions from many sources and could cause 3) long-lasting disruptive effects on human health and vital earth system processes.

Disclaimer/Disclosure: Acknowledgement - Funding is acknowledged under the European Union s Horizon 2020 research and innovation program project ZeroPM, under grant agreement No. 101036756, and the Horizon Europe project ARAGORN under grant agreement No. 101112723.

6.01.P-Mo452 A Multidisciplinary Perspective on the Role of Plastic Pollution in the Triple Planetary Crisis

Christian Schmidt, Dana Kuhnel, Dusan Materic, Jessica Stubenrauch, Kristin Schubert, Anran Luo, Katrin Wendt-Potthoff and ***Annika Jahnke****, Helmholtz Center for Environmental Research (UFZ), Germany*

The ubiquitous presence of plastics and associated chemicals threatens ecosystems and human health. However, in many cases plastics are considered a waste problem whereas other impacts are poorly understood. To quantify our state of knowledge on the links of plastics to the triple planetary crisis of environmental pollution, climate change and biodiversity loss, we conducted a literature analysis to discuss the negative impacts of plastics and associated chemicals from a multidisciplinary perspective. We analyzed that in addition to being part of the pollution crisis, plastics impact climate change and accelerate biodiversity loss, hence aggravating the triple planetary crisis. The literature survey revealed knowledge gaps regarding the life cycle, release, fate, exposure, hazard and governance of plastics and associated chemicals, as well as links to climate change and biodiversity loss. Core pollution-related knowledge gaps include exposure to chemicals from plastics in-use, uptake from the air and fate in specific compartments, such as the cryosphere. When assessing the impacts on climate change, major impact pathways include life cycle-related emissions of greenhouse gases, alterations of the global carbon cycle and changes of the albedo. Regarding biodiversity loss, the impacts of plastics and associated chemicals on toxicity are comprehensively studied on low levels of biological organization, but rarely at ecosystem level. Further impact pathways include, amongst others, rafting of invasive species and pathogens as well as altered habitats. We also explore links to political and legal sciences, which need to be strengthened. Our major conclusions include: (i) The contributions of plastic pollution to the triple planetary crisis need to be better understood to deduce the right strategies / measures for reduction. (ii) In-use plastics may be the most relevant human exposure source to plastics and associated chemicals. (iii) Regulation, in particular of plastic additives as well as in-use plastics, is largely missing. (iv) Our analysis revealed knowledge gaps that only comprehensive multidisciplinary efforts can address. (v) Effective plastics governance should be aligned with climate and biodiversity goals. We urge bridging disciplinary expertise from natural and social sciences to achieve effective plastic governance and risk management of plastics and associated chemicals that protect the Earth, its ecosystems and human health.

6.01.P-Mo453 Combining Methods to Characterize the Planetary Boundary for Chemical Pollution

***Leo Posthuma**[1], Stefan C. Dekker[2], Mark Huijbregts[3] and Detlef van Vuuren[4], (1)RIVM/DMG and Radboud University, Netherlands, (2)Copernicus Institute, Utrecht University, Netherlands, (3)Radboud University, Netherlands, (4)PBL and Copernicus Institute, Utrecht University, Netherlands*

Charting transitional pathways to move society towards sustainable and just practices is challenging especially for chemical pollution: the diversity of chemicals is vast, as is the variability of exposure to and

effects of unintended ambient mixtures and of ecosystems. In this presentation, we describe a vision on combining science-based methods to characterize the planetary boundary for chemical pollution, some very recent. The combined methods recognize that chemical pollution causes diverse effects via the transgression of local and regional boundaries, over longer terms. The challenges that this poses are addressed by a systematic approach that allows to derive conclusions on safe and just approaches in chemical management. In this approach, we consider the issue of chemical pollution vis a vis impacts on biodiversity, together representing two of the three planetary crises of this time.
We propose the following building blocks to be combined. First, we propose to employ scenario approaches. Via Shared Socio-Economic Pathway, as used in many planetary assessment contexts, the scenarios deliver chemical emission outlooks. Second, via multi-media fate modeling, the scenario-specific emissions are translated into regional steady-state concentrations. Third, via species sensitivity distribution and mixture modeling, the latter are translated into mixture toxic pressure levels. Fourth, via ecological modeling and supported by validation studies that link toxic pressure to biodiversity impacts, those are translated into damage levels, expressed in terms of biodiversity impacts. As additional step, fifth, novel methods (especially pairwise learning methodologies) for bridging data gaps are employed, given that for example hazard data lack for many chemicals*species pairs. Recently, such methods have shown that hazard data can be obtained for a very large number of chemicals.
Eventually, the stepwise methodology can characterize the distance to target of specific chemicals, chemical groups, economic activities and alternative socio-economic scenarios to the impact boundaries of chemical pollution at various spatial scales. It would also allow inverse modeling to identify which human activities and associated emissions contribute most to moving to (or beyond) the boundaries, even if the latter remain uncertain. Netto, the stepwise approach aims to provide insights to navigate a safe and just corridor for chemical pollution.

6.01.P-Mo454 Where is the Greta Thunberg for Chemicals? A Discussion on Effective Advocacy and the Importance of Youth Perspectives in Earth System Boundaries
Anna Shalin[1] *and Jonathan Blumenthal*[2]*, (1)University of Toronto, Canada, (2)ETH Zurich, Switzerland*
Climate change, biodiversity loss, and chemical pollution threaten us all; dealing with these issues should be a goal for everyone. But, as the triple planetary crisis deepens, it is the youth of today, and the generations to come, that have the most to lose. Exposure to hazardous chemicals has been linked to an unprecedented rise in cancer rates among young people, alarming decreases in fertility, and an array of endocrine disorders. At the same time, hazardous chemicals are poisoning the supplies of water and food on which future generations will have to rely.
While youth have taken up the causes of climate change and biodiversity loss, and through advocacy succeeded in generating movement on these issues, there has not been comparable activism on the issue of safer chemical management. We contend that this lack of activism stems from an absence of decision-making bodies and political fora in which youth can participate, and, more importantly, the lack of a clear vision for a future where chemicals are used and managed responsibly.
Only recently has chemical pollution begun to receive political attention on a level similar to that of climate change or biodiversity loss. As a result, work is still ongoing to promote the International Panel on Chemical Pollution, and to define the planetary boundary for novel entities. Neither effort will be easy chemical pollution is inherently complex given the wide variety of chemicals in use but both should seek to engage youth to identify what generational fairness and equity in chemicals management will look like. Young activists should be provided with dedicated advocacy platforms, like the UN Youth Climate Summit, to allow for dialogue with researchers and policymakers.
The participation of youth in policymaking will help to address the other major barrier to youth participation: the lack of a clear vision for responsible chemical management. For all its flaws, the 2 degree goal for climate change recommended by the IPCC has become a rallying point for activists, providing a clear and actionable goal for them to advocate. Establishing safe and just Earth system boundaries, even if more challenging and subjective for chemicals, should be urgently prioritized. Activist groups, and youth groups in particular, have proven to be capable of driving the discussion and securing commitments on the issues of climate change and biodiversity loss. It is time to empower them to do the same for chemical pollution.

6.02 Tackling the Triple Planetary Crisis: Implementing Lessons Learned from the Past 30 Years of Research and Regulations to Solve Present Challenges

6.02.T-01 Effective Risk Management of Chemicals in a Changing Environment
Elin Leander*, Marlene Ågerstrand and Christina Ruden, Stockholm University, Sweden*
The triple planetary crises of climate change, biodiversity loss, and pollution are closely linked, but the

impact of pollution from waste and chemicals on biodiversity is less studied than the effects of climate change. Climate change will further stress Baltic Sea marine life, already exposed to hazardous chemicals, due to rising temperatures, lower oxygen levels, and increased toxins from cyanobacteria. With the environment already under pressure and chemical production rising, urgent action is needed to prevent further harm to both human health and the ecosystem.
Indication that regulatory action can be effective in reducing the risk is seen in the case of regulation on pesticides and substances subject to REACH authorization, which has effectively decreased the volume of the most harmful substances put on the market. However, both regulators and researchers underline the importance of improving the EU chemicals legislation. There is a need for more knowledge on what is an effective measure or not, to better assess whether the objectives of EUs chemical policy, to protect human health and the environment, are being met.
In our project we are investigating the effectiveness of chemical management measures with the purpose of understanding if and how current management measures can be improved. For this, a series of case studies is performed evaluating management measures using data on the production and import of chemical products, time-series of biomonitoring and effect monitoring. This is mapped against the performed management measures, in order to find correlations between an intervention and an effect. The starting point is regulatory measures, such as REACH restrictions and CLP classifications and international agreements tackling pollution.
This research contributes to expanding the knowledge base on environmental management and the role of effective risk reduction of chemicals for healthy ecosystems in the Baltic Sea. This is policy-relevant knowledge that can contribute to using societal resources more effectively for protecting human health and the environment. It is important for future risk management of chemicals to be more effective in reducing the risk of contaminants ending up in the Baltic Sea and threaten the already stressed costal ecosystems which are of great importance for climate mitigation.

6.02.T-02 Lessons Learned for Greening the Pharmacy: A Lock-in Analysis Towards Solving the Triple Planetary Crisis
Anna Shalin[1]*, Miriam L. Diamond*[1] *and Zhanyun Wang*[2]*, (1)University of Toronto, Canada, (2)EMPA - Swiss Federal Laboratories for Materials Science and Technology, Switzerland*
Despite efforts towards sound chemicals management, widespread use of hazardous chemicals persists globally. Blumenthal et al. (2022) proposed that the concept of lock-in allows analysis of reasons for and ways to overcome barriers to the continued use of hazardous chemicals. Here, lock-in refers to complex interactions between economic, social, technological, and political factors that reinforce the status-quo. Our study aimed to extend the understanding of lock-in by conducting a case study on the pharmaceutical industry. While the use of drugs has led to major health improvements, their widespread production and consumption also has led them to become globally pervasive in environmental media, leading to harmful impacts to non-target organisms.
Creative solutions are needed to allow for the beneficial uses of pharmaceuticals while minimizing negative impacts to the environment this is highlighted by the recent concept of greening the pharmacy by Orive et al. (2022). While some technical solutions are seemingly promising, it is unclear if the industry is undergoing systematic change towards safer alternatives. For example, approvals of fluorine-containing drugs are increasing despite concerns over PFAS persistence and potential harmful breakdown products like TFA. Thus, our study aims to understand the barriers preventing large-scale transformation of the pharmaceutical industry towards safer chemistries.
The hypothesis is that a combination of economic, social, political, and technological factors creates a "lock-in" that keeps things as they are. This system of drug design prevents the industry from making large-scale changes toward environmentally friendly practices, meaning current technical solutions will be less effective unless lock-ins are addressed.
We identified two major lock-ins. Lock-in 1 shows how misaligned environmental safety testing timelines hinder the development of safer future drugs. Lock-in 2 highlights how the industry s profitability-driven model favors new drug development over revising existing ones, creating a barrier to improving drugs already on the market.
The lesson learned is that addressing both lock-ins is essential for any technical solutions to greening the pharmacy to be truly effective. In response to this, we propose a strategic approach to identifying leverage points within complex systems which can be used as a tool for meaningful policy interventions both within the pharmaceutical industry and beyond.

6.02.T-03 A Decision Support Tool for Choosing Pesticides with Lower Risks to Aquatic Environments
Hannah Mitchell[1]*, Michael St. J. Warne*[1]*, Peta A. Neale*[2]*, Rob Sluggett*[3]*, Reinier Mann*[4]*, Cath*

Neelamraju[1] and Ryan David Ralph Turner[1], (1)University of Queensland, Australia, (2) Griffith University, Australia, (3)Farmacist Pty Ltd, Mackay, Australia, (4)Water Quality and Investigations, Queensland Department of Environment, Tourism, Science and Innovation, Australia
Pesticide contamination from agricultural runoff is a major contributor to poor water quality in waterways discharging to the Great Barrier Reef (GBR) lagoon in Queensland, Australia. Water samples frequently contain pesticide at concentrations that exceed the Australian and New Zealand guidelines for ecosystem protection, and a recent study identified multiple waterways draining sugarcane dominated catchments as aquatic ecotoxicity hotspots. Previous efforts to reduce pesticide inputs into aquatic environments have focused on regulating problematic pesticide active ingredients (PAIs), improving farm management practices and improving application techniques. This project aimed to provide an alternative complementary approach that informed decisions about pesticide usage. The Pesticide Decision Support Tool (PDST) was co-designed with stakeholders including government, farmers, resellers, extension officers and agronomists. Initially developed for the sugarcane industry, it includes 104 PAIs registered for application on sugarcane and rotation crops in Queensland and has recently been expanded to include 34 PAIs registered for bananas. The PDST offers generic guidance on which PAIs pose lower potential aquatic risks, through a plot of environmentally relevant parameters: the measure of toxicological effect (MoE) and the measure of mobility and persistence (MoMP). The MoE indicates the potential of a PAI to exert harmful effects on aquatic organisms, based on aquatic toxicity and maximum application rate. The MoMP indicates the potential of a PAI to move from land via runoff and to persist in aquatic environments, based on environmentally relevant physicochemical properties. The PDST presents the aquatic risk as a continuum of values, allowing users to easily identify and select less environmentally harmful PAIs to control pests. Over a two-year period, the PDST was implemented into pesticide management plans, along with improvements to spraying equipment, through the Farmacist Pty Ltd led Project Bluewater . This resulted in a 29% reduction in herbicide application to 10,500 ha of sugarcane in the Mackay Whitsunday region in Queensland, and a 53% decrease in total relative risk units. This highlights the potential for voluntary farm education programs in reducing the impact of PAIs on aquatic environments.

6.02.T-04 Stakeholder Perceptions on the Socio-Technical Factors Affecting the Use of Evidence in Europe(an Chemical Assessment and Management)
***Lowenna Bethany Jones**[1], Kathryn Arnold[2] and Charlotte Burns[1], (1)University of Sheffield, United Kingdom, (2)University of York, United Kingdom*
The need for a modern, science and/or evidence-based approach to chemical safety assessment is an increasingly urgent topic of conversation and research. Academic research is one of the many sources of evidence that inform chemical assessment and management, however in practice, academic toxicity studies face challenges to their use. In recent years there has been a significant increase in attention on who is undertaking regulatory assessments, and what data are considered in decision making processes, however, little attention has been given to how evidence (including academic research) is taken up and used for regulatory decision making. Our project explores the factors as perceived by stakeholders, that challenge the uptake and use of academic research in European chemical assessment and management. A survey consisting of Likert-scale, multiple choice and free text response questions was designed to collect and understand stakeholder perspectives on the uptake and use of evidence in European chemical assessment and management. 58 individuals responded to the survey including those in Academia (N=8), Consultancy (N=10), Government (N=22) and Industry (N=14). We find that there is a general lack of consensus on the current uptake and use of evidence, whilst actors across the regulatory toxicology system hold a range of views on the utility and role of academic research for regulatory decision making. We find general consensus on what factors are considered to challenge the uptake and use of academic research. These include a broad range of social factors (i.e. social, cultural, political, and economic considerations; N=9) and technical factors (i.e. technical, scientific, and regulatory considerations; N=3). These include highly ranked factors such as, regulatory needs and requirements (57%); expertise and resources (47%); goals and demands (40%); and legislative processes (40%). We find that technical factors are often interconnected or dependent on social factors, whilst some factors exhibit both social and technical dimensions. We conclude that the development of solutions demands a coordinated, systems level approach whilst offering some immediate recommendations for actors across the regulatory toxicology system to increase the uptake and use of academic research. Though the focus of this research is on European assessment and management, we consider the factors identified to be applicable to other jurisdictions and global settings.

Disclaimer/Disclosure: This project was funded by the UK Natural Environmental Research Council, Grant Number: NE/VO13041/1.

6.02.T-05 The Societal Risks of Risk Assessment

Ad Ragas, *Radboud University Nijmegen, Netherlands*

Chemical risk assessment evolved from the 50s of the last century in an attempt to control the human and ecological risks associated with the widespread production and use of chemicals. But did we succeed? Are our risk assessments beneficial to society?

In this critical contribution, I will argue, based on more than 30 years of experience in the risk assessment field, that we should redefine the role of chemical risk assessment in society. Bottom line: chemical risk assessments should become simpler, more conservative and less important.

My analysis starts by looking at the past: did our chemical risk assessments provide the protection we aimed for? There are many examples and indicators showing that chemical risk assessment currently fails to sufficiently protect human health and ecosystems. I attribute this to the chemical diversification and the inherent uncertainties in chemical risk assessment which are insufficiently acknowledged in current regulations. The uncertainties are a consequence of reductionist approaches, e.g., assessing individual compounds instead of mixtures and testing a limited set of species instead of an ecosystem. The default response to these uncertainties, i.e., more science, results in complex analyses and reports which are difficult to understand and verify by key stakeholders such as policy makers and concerned citizens. The occasional erroneous assessment (e.g., of neonicotinoids), the influential role of industry and the lack of resources and expertise for concerned citizens result in a poisonous cocktail, feeding concerns and distrust.

One of my hypotheses is that we as a risk assessment community, and as a society, put too much faith in the science underlying chemical risk assessment. This can be partly explained by (technological) optimism, resulting in unrealistic expectations of the sciences studying complex systems, such as ecology and toxicology. We should acknowledge that we do not fully understand the complexity of life. This means simpler and more conservative assessments which have the advantage of being more understandable for policymakers and concerned citizens. A first step could be the introduction of a default mixture assessment factor when allowing new substances on the market.

6.02.P Tackling the Triple Planetary Crisis: Implementing Lessons Learned from the Past 30 Years of Research and Regulations to Solve Present Challenges

6.02.P-Mo455 Key Elements of a Sustainable and Protective Chemical Control Strategy

Marlene Ågerstrand[1], *Mathilda Andreassen*[1], *Flora Borchert*[2], *Natasja Borjeson*[1], *Romain Figuière*[1], *Elin Leander*[1], *Axel Mie*[1], *Persa Xyderou*[1] *and Christina Ruden*[1], *(1)Stockholm University, Sweden, (2)ACES, Stockholm University, Stockholm, Sweden*

"This study presents findings from research on the key elements of a sustainable and protective chemical control strategy. By adhering to these elements, we can build a resilient regulatory system capable of addressing current and future challenges in chemical safety. The key elements are:

1) Comprehensive and Pro-active: A sustainable approach prioritizes long-term solutions, such as the design of non-toxic substances and products from the outset and the integration of pest management strategies. Critical to this pillar is access to robust and sufficient data that enables comprehensive hazard assessments of chemical substances.

2) Innovative and Relevant: Chemical control strategies must adapt to evolving scientific knowledge and technological advancements. This includes incorporating new data on hazards and exposures, leveraging innovative testing methods, and embracing advancements in materials science. The aim is to foster a society that incentivizes the refinement, reduction, and replacement of hazardous chemicals.

3) Efficient and Effective: The strategy relies on both enabling the market entry of safer chemicals and swiftly restricting or banning hazardous substances. Streamlining the approval process for new chemicals can drive innovation towards safer alternatives. It is essential, however, to balance efficiency with maintaining transparency, objectivity, and rigour in data evaluation and risk assessment.

4) Transparent and Objective: Full transparency in data and chemical assessments should be the standard practice. The recent EU transparency rules for food law set an important precedent that can be expanded to broader chemical regulation. A systematic approach to identifying and managing conflicts of interest is vital to uphold the objectivity of the regulatory process.

5) Enforced and Fair: A robust regulatory system must include effective enforcement mechanisms to deter non-compliance. This requires a reasonable likelihood of detecting violations and implementing sufficiently dissuasive penalties.

6.02.P-Mo456 Assessing EU's Legal Frameworks: Hazard Classification and Data Generation under CLP Criteria

***Mathilda Andreassen**, Marlene Ågerstrand and Christina Ruden, Stockholm University, Sweden*

In the context of the triple planetary crisis of climate change, pollution, and biodiversity loss, addressing chemical pollution remains a critical challenge for protecting ecosystems and human health. One important aspect in adressing chemical pollution is identifying and regulating hazardous chemicals. With the Chemical Strategy for Sustainability (CSS), the EU Commisson described the goal of a stronger EU chemicals legislation to faciliate the transition toward a toxic-free environment. The CSS outlines two important steps towards this goal. The first is to ensure that the CLP regulation, which implements the Globally Harmonized System of Classification and Labelling of Chemicals (GHS) in the EU, becomes the central piece for hazard classification. The second is to make the generic approach to risk management the default for managing the most harmful chemicals, i.e., chemicals that are carcinogenic, mutagenic, reprotoxic, endocrine disruptors, or persistent and bioaccumulative. Over time, the scope also aims to include chemicals that affect the immune, neurological, or respiratory systems, as well as those toxic to specific organs. To enhance the protection of human health and the environment and to effectively extend the generic approach to risk management, the goals of the CSS emphasize the need for sufficient and reliable information generated across legislation to ensure consistent hazard identification and classification. A hazard classification enables substances to be regulated systematically based on their hazards, which allows for improved regulatory efficiency, consistent hazard assessment, and the reuse of information across borders. The later also support efforts toward a harmonized global framework for chemical management. In regards to this, we conducted an analysis of the current state of hazard assessments for the most harmful endpoints identified according to the CSS to evaluate whether the existing legal frameworks in the EU adequately supports data generation for classification according to CLP criteria. This involved a combination of document analysis of the legal frameworks and case studies of classified substances, providing an in-depth examination of the data utilized for classification and assessing whether such data could have been produced in compliance with the data requirements outlined in EU legal frameworks.

6.02.P-Mo457 Assessing Risks to Biodiversity from Exposure to Chemicals: ECETOC Task Force Findings and Next Steps

*Marta Baccaro[1], David A. Bohan[2], Sian Ellis[3], Franziska Enzmann[4], Nika Galic[5], Emily Rogevich Garman[6], Anja Gladbach[7], Jutta Hellstern[8], Sarah A. Hughes[9], Philippe Lemaire[10], Jan-Dieter Ludwigs[11], **Lorraine Maltby**[12], Christoph Mayer[13], Anna-Maija Nyman[14], Claudia Rivetti[15], Hans Sanderson[16], Simran Sandhu[15], Aaron Stoler[17], Marco Thines[18] and Johannes Tolls Dir[4], (1)Joint Research Centre (JRC), Italy, (2)INRAE, France, (3)Corteva Agriscience, United Kingdom, (4)Henkel AG & Co, Germany, (5)Syngenta Crop Protection AG, Switzerland, (6)NiPERA Inc, United States, (7)Bayer AG, Germany, (8)F-Hoffman-La Roche, Switzerland, (9)Shell, United States, (10)Total Energies, France, (11)Rifcon, Germany, (12)University of Sheffield, United Kingdom, (13)BASF, Germany, (14)European Chemicals Agency (ECHA), Finland, (15)Unilever, United Kingdom, (16)Aarhus University, Denmark, (17)ExxonMobil, United States, (18)Senckenberg Biodiversity and Climate Research Centre, Germany*

The Kunming-Montreal Global Biodiversity Framework was adopted in December 2022 and sets out an ambitious pathway to reach the global vision of a world living in harmony with nature by 2050. Three targets of this framework (7, 14, and 15) link to assessment of risks to biodiversity from chemical exposure.

There is an increased focus in the EU on potential impact on biodiversity from chemical exposure, as evidenced by several initiatives of the European Green Deal, such as the Farm to Fork Strategy, the Zero Pollution Action Plan and the Biodiversity Strategy for 2030.

Assessing impacts of chemical on biodiversity is challenging due to the multifaceted way biodiversity is described and measured and the lack of a unified approach to quantify the effects of chemical pollution on biodiversity, especially considering the impact from other pressures such as climate change and habitat destruction.

ECETOC launched a Task Force in 2023 to review the state of the science for assessing the impact of chemical exposure on biodiversity. The Task Force: reviewed relevant regulatory and policy documents relating to chemicals to identify to what extent impact on biodiversity is already considered; gained an overview of the EU research projects on biodiversity and chemicals; and investigated biodiversity definitions and metrics used in the scientific and regulatory domains.

It was identified that biodiversity is a poorly defined term and this is reflected in EU regulatory and policy documents, whilst mention of the term biodiversity has increased in these document in the past few decades. It was further highlighted that there has been a significant and increasing number of research projects relating to chemicals and biodiversity in recent years though such research has so far not

translated into actionable recommendations. In terms of biodiversity metrics and measures, these were found to vary according to ecosystem. Among the Essential Biodiversity Variables (EBV) definitions, trait diversity and ecosystem function are the most widely applied.
The key findings from the ECETOC Task Force will be presented, along with an overview of an ECETOC workshop planned for Q4 2025 which will aim to develop an approach to assessing impacts of chemicals on biodiversity across the chemical sectors based on the current state-of-the-art knowledge and tools in biodiversity research.

6.02.P-Mo458 RE-MIX: Options to Assess and REgulate Chemical MIXtures - A New PARC Cooperation Towards Regulatory Solutions

*Enken Hassold[1], **Marion Junghans**[2], Veronika Plichta[3], Daniel Frein[1], Urban Boije af Gennas[4] and Lina Wendt-Rasch[4], (1)UBA, Germany, (2)Swiss Ecotoxcentre, Switzerland, (3)Austrian Agency for Health and Food Safety (AGES), Austria, (4)KEMI, Sweden*

EU regulations are still largely focused on the assessment and management of single substances. This holds true for substance-oriented legislations such as REACH chemicals or pesticides, but also media-oriented frameworks such as the water framework directive. The need to address the co-exposure of multiple chemicals to humans and the environment has been highlighted by the European Commission s Chemical Strategy for Sustainability and is one of the identified needs of the European Partnership for the Assessment of Risks from Chemicals (PARC).
Re-Mix is starting in May 2025 as a cooperation between regulatory and academic scientists in PARC. It aims at bringing together expertise from various areas (human health and the environment). The overall aim is to support regulation by providing evidence for magnitude of mixture risks in various media, agree on assessment methodologies and tools and propose feasible options to introduce requirements for mixture risk assessment and mixture risk management in different regulations.
It will build upon previous work and include a landscaping exercise. ?As starting points, the generic option to introduce a mixture allocation factor (MAF) in REACH as well as its applicability for other legislations will be analysed together with case-by-case mixture risk assessments are evaluated as way forward. Further, a number of concrete case studies of the partners will substantiate regulatory solutions with evidence for mixture risks in different media, and concrete comparisons of methods and options. The project will foster collaboration between regulation and academia and EU agencies via a regular Forum for Exchange for presentation of key results which is aimed at being open for participants of other PARC activities as well as EU agencies.

6.02.P-Mo459 Co-Occurrence of Chemicals in the Environment and Their Mixture Risks – (First Results From) a Literature Review

***Marius Schubert**, Gabriele Treu and Enken Hassold, UBA, Germany*

The widespread discharge of chemicals into the environment has raised considerable concerns about their impacts on ecosystem integrity. Despite this, continuous industrial development has led to an increasing complexity of pollution released into the environment. It is evident that multiple chemicals co-occur in variable compositions across environmental compartments, sites, and time, all of which have the potential to pose combined risks. Until recent years, ecotoxicological research, monitoring and regulatory assessments have mainly focused on single substances or substance classes. Recent advancements in the fields of analytical chemistry and risk assessment have enabled investigating the risks of chemical mixtures pollution. Monitoring studies on measured concentrations of substances in the environment are increasingly focusing on multiple co-occurring substances and calculating their potential mixture risks and effects in the environment.
In this poster, we systematically gathered available literature evaluating measured environmental concentrations of multiple substances and estimating mixture risks, with the goal of examining the current state of monitoring studies dealing with unintentional environmental mixtures in European countries. We quantify the number of studies addressing different environmental compartments, substance classes, and geographic focal points to identify gaps for future research. We also delve deeper into the subject of mixture risk assessments, evaluating the applied methodologies for environmental monitoring and estimations of mixture risk, to provide an overview of the current tools for mixture risk assessment and the magnitude of the issue. As an outlook, we summarize the current state of research evaluating observed environmental damage linked to mixture pollution. This article aims to provide a comprehensive review of monitoring-based mixture pollution research as bases for revising future risk assessment practices. Fully understanding the exposures, effects, and risks of unintentional environmental mixtures is essential for developing effective regulations to improve environmental protection, especially as current European regulations fail to meet the challenges posed by mixtures.

Disclaimer/Disclosure: This project received funding from the German Federal Environment Agency and Partnership for the Assessment of Risks from Chemicals (PARC).

6.02.P-Mo460 Screening Concept for the Hazard Assessment of Green Platform Chemicals
***Simone Muhlegger**, Regulatory (eco)toxicologist, Austria*
Biobased platform chemicals have a potential to become a green alternative to current petro-based chemicals. It can be anticipated that the volume of biobased platform chemicals on the European market will increase significantly in the near future leading to enhanced emissions and new risk situations. Therefore, a need to comprehensively assess the (eco)toxicity of these potentially green substances is identified. The Environment Agency Austria has developed a screening concept for the hazard assessment based on (partially limited) data availability and hazardous properties of such chemicals.
For categorization and prioritization, inter alia, the REACH Regulation criteria for substances of very high concern (SVHC) and the criteria for substances of concern (SOC) from ESP-Regulation were used. Also, relevant harmful environmental properties including terrestrial and sediment toxicity were considered. The data availability was examined based on information requirements according to the REACH regulation, which were supplemented with envisaged information requirements for endocrine disruption and mobility. To reflect the new toxicity (T) criterion in the CLP Regulation for persistent, bioaccumulative and toxic (PBT) as well as persistent, mobile and toxic (PMT) substances, a screening approach was developed.
The outcome of this pilot project shows that the proposed screening concept is a suitable tool not only for assessing the need for specific additional information to fill data gaps for potential green plattform chemicals, but also to categorise these chemicals into four hazard categories, depicted with traffic light symbols. These indicate the individual hazard potential and thus provide a first screening approach with respect to their relative hazards. This assessment of available data requires significant expert judgement in different fields of hazard assessment.
This work wishes to provide additional support and guidance for industry, eventually motivating for and assisting in the transition to the use of more sustainable chemicals.

6.02.P-Mo461 Survey of Green Platform Chemicals
***Josef Kerschbaum**[1], Martin Wimmer[2], Eva Stocker[3], Ilse Mauritz[3], Michael Schnurch[1] and Marko Mihovilovic[1], (1)TU Wien, Austria, (2)Federal Ministry Republic of Austria Climate Action, Environment, Energy, Mobility, Innovation and Technology, Austria, (3)Environment Agency Austria, Austria*
Despite the huge progress that chemical policy has achieved in the last years to control the risk of chemicals, fossil resource use as well as pollution by chemicals are still considered as two of the main concerns in the triple planetary crisis. Thus, the chemical strategy for sustainability considers the transition of chemical industry towards safe and more sustainable chemicals as a major challenge for future chemical policy, management and industry. For this reason, the development of safe and sustainable by design (SSBD) alternatives in the current chemical management are highly searched for. The concept of green chemistry has become an important innovation in this context aiming at the transformation of the current chemical production which is fossil based and involves substances bearing high hazardous potential. In literature the term green platform chemicals have become a key concept describing the chemical bases for such an alternative approach.
While the colour green symbolizes entities which are derived from nature in our societies and therefore genuinely considered as benign for humans, examples like phyto- and mycotoxins are in strong contrast to that picture. This cliche may also apply to green platform chemicals. Therefore, this work was aiming to investigate green platform chemicals with respect to their potential hazard based on existing and publicly available data. For this purpose, literature has been searched for the substances proposed as green platform chemicals. The identified list of substances has been further screened with respect to their hazardous properties and the regulatory activities using the European chemicals agency s website as information bases. As a promising result, 63% of the 131 surveyed substances are relatively data rich substances (being registered as manufactured/imported in volumes higher than 10 tons per year in the EU) and are of comparatively low potential hazard based on this investigation. Therefore, these bio-based substances could potentially serve as substitutes for their more hazardous and less sustainable fossil equivalents. It is recommended that the assumption of these chemicals being of low hazard should be investigated and confirmed. Furthermore, these substances should be subject to an in-depth analysis e.g. Life-cycle assessment to identify them as SSBD chemicals for industry.

6.03 Scientific Input to the New Global Science-Policy Panel

6.03.T-01 Thought-Starter on Broadening the Impact of the Science-Policy Panel through a Scientific Knowledge Holder Network

Sherika Whitelocke-Ballingsingh[1], Mohamed Abdelraouf[2], Sofia Schlezak[3] and ***Anna Isabel Becker[4]****, (1)University of Technology, Jamaica, (2)Gulf Research Center Foundation, Switzerland, (3)United Nations Institute for Training and Research (UNITAR), Switzerland, (4)International Sustainable Chemistry Collaborative Centre (ISC3), Germany*

UNEA-5 agreed on developing a new global Science-Policy Panel (SPP) for the sound management of chemicals and waste and to prevent pollution. In 2022 an ad hoc open-ended working group (OEWG) process has been initiated to prepare proposals for the panel and the delegates will meet for a resumed session (OEWG 3.2) in early 2025, back to back with an intergovernmental meeting to consider the establishment of the SPP.
The broad participation of the scientific knowledge holders in the new SPP will be key to ensuring that this panel meets its objectives and adheres to its integrative character. This broad participation should go beyond the foreseen Interdisciplinary Expert Committee (IEC) as the pressing topics of chemicals, waste and pollution prevention need support from as many relevant knowledge holders as possible and across disciplines, including natural sciences, social sciences, and humanities.

The information shared in this paper, provide the base to open up the discussion for a more holistic and systematic approach for the involvement of scientific knowledge holders in the context of the panel. The informations is based on observations and experiences at OEWG 3, Geneva, Switzerland in 2024. Building on the insights a more systematic approach of including underrepresented groups of scientific experts, disciplines as well as experts that are not yet familiar with international science-policy work could be envisaged in the future.

The observations highlight that in both, the current negotiation process under the OEWG and the future SPP, open questions persist among the SPP s target group scientific knowledge holders. These include the avenues for scientists involvement, the complexity of the political process particularly for newcomers and concerns about the understanding of scientific institutions and principles, current lack of broader expertise, imbalance of regional representation among scientists involved in the SPP. The findings provide evidence that a network flanking the panel s activities could be beneficial to the objectives of the panel. It could include the expertise of scientists who do not only come from the chemicals, sustainability, and waste sectors, but also range from social sciences, humanities to economy studies. Scientist that are new to the policy process can benefit from a network that they could approach and learn from peers.

Disclaimer/Disclosure: NB: An initiave for a network has started and operates under the name SPP Science Alliance .

6.03.T-02 The role of university research in safeguarding the planet from chemical pollution

Alex Ford[1], Miriam L. Diamond[2], Marlene Ågerstrand[3], Michael Grant Bertram[4], Steffen Foss Hansen[5], Annika Jahnke[6], Rainer Lohmann[7], Andreas Schaffer[8], Anna G Soehl[9], Gabriel Sigmund[10], Maria Clara Starling[11], Noriyuki Suzuki[12], Marta Venier[13], Penny Vlahos[14] and ***Martin Scheringer[15]****, (1)University of Portsmouth, United Kingdom, (2)University of Toronto, Canada, (3)Stockholm University, Sweden, (4)Swedish University of Agricultural Sciences (SLU), Sweden, (5)Technical University of Denmark, Denmark, (6)UFZ, Germany, (7)University of Rhode Island, United States, (8)RWTH Aachen University, Germany, (9)IPCP, Germany, (10)Wageningen University, Netherlands, (11)Universidade Federal de Minas Gerais, Brazil, (12)National Institute for Environmental Studies (NIES), Japan, (13)University of Indiana, United States, (14)University of Connecticut, United States, (15)ETH Zurich, Switzerland*

Universities worldwide have greatly benefited societies spanning centuries, by contributing to education and generating new knowledge. Here we highlight the pivotal role independent science conducted at universities has and continues to play in environmental sciences, focussing on environmental toxicology and chemical pollution research in terms of safeguarding the planet from chemical pollution. Independent university research produces the feedstock of innovative research and knowledge which has promoted and enabled local to global policy and regulation. For example, every global convention and policy instrument aimed at environmental protection can trace its origins back to seminal research originating from independent university research, e.g, the Stockholm Convention, or the Montreal Protocol. These contributions have come through the support of dedicated students and academics to conduct curiosity- and issue-driven inquiry to discover and understand the breadth of problems our planet faces and to pursue creative solutions. Key to this inquiry has been academic freedom and independence, as well as the provision of sufficient financial resources. Society is facing a triple planetary crisis of climate change, biodiversity loss and pollution which are closely interlinked. We argue that the role universities play in

developing solutions for healthy humans in a healthy environment this regard is acknowledged, supported and, importantly, protected

6.03.T-03 Indigenous People's Earth Observations, Knowledge and Practices in Chemical Governance. Enhancing Management and Monitoring

Yolanda López-Maldonado, *Indigenous Science, Mexico*

The regulation and governance of chemicals presents a complex challenge intersecting environmental protection, public health, and sustainable development. This paper explores the multifaceted nature of chemical regulation and governance, encompassing national laws, international initiatives, and the roles of various regulatory bodies. While existing frameworks provide some oversight, there is growing recognition that effective governance of chemicals requires an holistic and inclusive approach. The challenge lies in developing comprehensive and sustainable solutions to chemical management that integrate diverse knowledge systems, particularly those of Indigenous Peoples (IP) and local communities. These groups are often the most vulnerable to chemical contamination yet possess deep understanding of local ecosystems and sustainable practices. This study examines the importance of including Indigenous knowledge systems in the regulation, monitoring, and governance of chemicals affecting environmental and human health, including for example obtaining consent from Indigenous Peoples for any activities undertaken on their lands through the application of the Free Prior and Informed Consent form. I argue that this inclusion is not only a matter of social justice but also a strategic necessity for developing effective and equitable governance frameworks. Our approach involves analyzing existing chemical regulation frameworks, identifying gaps in current governance models, and exploring case studies where IP knowledge has been successfully integrated into environmental management practices, where such knowledge has been overlooked. Indigenous Earth Observations and knowledge can enhance our understanding of the long-term effects of chemicals on ecosystems and human communities, inform more sustainable approaches to chemical use and disposal, improve early warning systems for environmental degradation, and foster more local responses to chemical-related challenges. Findings suggest that involving communities in chemical governance can lead to more comprehensive risk assessments, culturally appropriate mitigation strategies, and improved environmental monitoring systems. Significant barriers to integration remain, including institutional resistance and lack of recognition of Indigenous rights. Results can be applied to policy development, regulatory reform, and community engagement strategies in chemical governance worldwide.

Disclaimer/Disclosure: I, Yolanda López-Maldonado, an indigenous scientist of Mayan heritage, hereby declare that I have not received any external funding, grants, or financial support for my research and scientific work. All studies and findings presented are the result of independent efforts and personal resources.

6.03.T-04 Mismanaged Plastic Waste and Interlinked Endocrine-Disrupting Chemicals in Indian Cities: Need for Effective Policy Interventions

Paromita Chakraborty, *Centre for Research in Environment, Sustainability Advocacy and Climate Change (REACH), Directorate of Research, SRM Institute of Science and Technology, India*

Plastics ending up in waste streams pose a significant challenge globally, particularly in low and middle-income countries. Among the myriad of concerns associated with plastic waste, one of the less explored yet highly consequential issues is the fate of endocrine-disrupting chemicals (EDCs) released during the burning or combustion of plastics. This study aims to investigate the fate of interlinked EDCs produced during waste plastic burning/combustion activities in India and their subsequent accumulation in local bovine milk. EDCs in plastics such as additives (phthalic acid esters, PAEs), brominated flame retardants (polybrominated diphenyl ethers, PBDEs, and polychlorinated biphenyls (PCBs) are evidenced as the primary conduits from the hotspot regions. Hotspots majorly indicate specific activities such as open burning of municipal solid waste, and informal recycling of plastic waste encompassing electronic and electrical waste. Furthermore, during the COVID-19 pandemic, the surge in plastic-based personal protective equipment (PPE) and dumped e-waste in the open dumps are the possible reasons for the increase in atmospheric PAEs, tetra and penta homologs of PCBs and heavier PBDE homologs compared to the pre-pandemic period. Prolonged environmental release of the EDCs was found to bio-accumulate in locally grazing cows, leading to increased concentrations of EDCs in bovine milk after three years of pandemic compared to pre-pandemic levels. Emerging policy frameworks including the Chemical Management and Safety Rules must account for the multi-pathway exposure to EDCs, an emerging public health concern. Risk evaluations in the Indian context are required to pave the way for elaborate monitoring and reporting avenues for efficient management and protection of the marginalized communities in India, who might be disproportionately affected by EDC exposure.

6.03.T-05 Problematisation of Plastic Pollution in the United Nations Plastic Treaty Negotiations – A Critical Interrogation of Pollution as an Issue of Environment, Waste, Economy and Health

Ellen Palm[1] *and Patrica Villarrrubia-Gomez*[2]*, (1)Roskilde University, Denmark, (2)SRC, Sweden*

The severity of the plastic crisis has spurred the need for global action. In the ongoing United Nations (UN) Plastic Treaty negotiations, member states are working toward a legally binding international instrument to address plastic pollution across its entire lifecycle. However, there is no consensus on how plastic pollution should be framed as a policy problem. As with all political processes, the framing of a societal or ecological issue shapes the potential policy outcomes. This paper conducts a critical social-ecological analysis of the Plastics Treaty negotiations, employing Bacchi s feminist approach of what is the problem represented to be? . Analysing the representations of plastic pollution, rather than the problem itself, offers a deeper understanding of the issue from a systems perspective, helping to contextualise systemic challenges within policy frameworks and promote a more inclusive approach. Drawing on participant observations and ethnographic analysis from the negotiation process, we identify four key problematisations of plastic pollution: environmental degradation, inadequate waste management, economic inefficiency, and negative human health impacts. However, the dominant problematisation of plastic pollution conceptualises it as an end-of-life materials problem. Failing to include other aspects of the plastics crisis in the UN Plastics Treaty could result in a narrow and more unjust implementation, potentially exacerbating the impact of plastic pollution. More broadly, this study highlights the marginalised societal impacts of plastic pollution and contributes to the growing body of research on the power relations among actors in and around the Plastics Treaty, the plastic industry, and oil-producing member states.

6.03.P Scientific Input to the New Global Science-Policy Panel

6.03.P-Mo462 A Systems Analysis of the European Green Deal: Policy Framework and Science-Policy Interface for Global Environmental Governance

Ayazhan Nurpeiis*, Tsinghua University, School of Environment, China (Mainland)*

Chemical pollution, biodiversity loss, and climate change represent interconnected global environmental crises requiring coordinated policy responses. The European Green Deal (EGD) stands as one of the most comprehensive policy frameworks addressing these challenges, offering valuable insights for the new Global Science-Policy Panel on chemical management and pollution prevention.

This study addresses the challenge of translating scientific evidence into effective environmental governance by analyzing how the EGD integrates scientific inputs into policy decisions. I examine how this framework could inform the development of similar initiatives globally, particularly in the context of the new UN Science-Policy Panel.

The research employs a systems analysis approach, combining policy document analysis, stakeholder interviews, and comparative policy assessment. I evaluate the EGD's mechanisms for incorporating scientific evidence into policy-making, focusing on chemical pollution control, circular economy initiatives, and cross-border policy coordination.

Preliminary findings indicate that the EGD's success in bridging science and policy relies on three key elements: (1) structured pathways for scientific input in policy formulation, (2) adaptive management mechanisms responding to emerging scientific evidence, and (3) integrated assessment frameworks that consider multiple environmental stressors simultaneously. The analysis reveals both strengths and limitations in the EGD's approach to science-based policy-making.

This research concludes that the EGD's framework offers valuable lessons for the Global Science-Policy Panel, particularly in establishing effective science-policy interfaces. The findings provide practical insights for developing robust mechanisms to translate scientific knowledge into actionable policy measures at the global level. This work contributes to the ongoing development of the UN Science-Policy Panel by identifying successful approaches to integrating scientific evidence into environmental governance frameworks.

6.03.P-Mo463 Defining Intrinsic Chemical Properties in the context of Global Chemical Regulations

Hans Peter H. Arp*, NGI/NTNU, Norway*

In the United Nations Globally Harmonized System of Classification and Labelling of Chemicals (GHS), only intrinsic hazards or properties are labeled. Non-intrinsic properties are out of scope. Carcinogenicity, flammability, and molecular weight are intrinsic properties. When new hazard classes like Endocrine

Disruptors or Persistence and Bioaccumulation are introduced, their intrinsic nature must be clarified, which can be confusing due to environmental influences. This poster clarifies Intrinsic Chemical Property from philosophical and science-policy perspectives for new hazard classes, which is relevant for the Global management of chemicals.

Philosophically, an intrinsic property is one an object has regardless of context. For example, a square's shape is intrinsic, while its size or weight is extrinsic. However, debates exist about whether shapes are truly intrinsic, as their manifestation can depend on space-time context.

In chemistry, intrinsic properties are independent of the chemical's amount, such as molecular mass, bonds, melting point, and boiling point. These properties are intrinsic despite being influenced by external factors like gravity and pressure. For toxic hazards, risk is an extrinsic property. According to Paracelsus, the dose makes the poison, meaning dose is an extrinsic property of the intrinsic hazard.

Environmental classes like persistence and mobility are also intrinsic. The UN-GHS states that persistence is based on intrinsic properties, though degradation depends on environmental conditions of the receiving environment. To quote the UN-GHS: [Persistence] is "primarily based on [ ] intrinsic properties. However, the degree of degradation depends not only on the intrinsic recalcitrance of the molecule, but also the actual conditions in the receiving environmental compartment . Mobility, the potential of a substance to move through the environment, is like persistence, based on intrinsic properties independent of amount (size, surface charges, dipolarity), but its degree depends on environmental conditions of the receiving environment (redox potential, pH, adsorptive phases, substance concentrations).

Based on these definitions of an "intrinsic chemical properties", new hazard classes like PBT/vPvB and PMT/vPvM should be added the UN-GHS, to facilitate global management.

Disclaimer/Disclosure: This project has received funding from the European Union s Horizon 2020 research and innovation programme under grant agreement No 101036756 (ZeroPM)

6.03.P-Mo464 Considerations on Chemicals Sound Management

Anahit Aleksandryan[1] *and Artak Khachatryan*[2]*, (1)Ministry of Environment of the Republic of Armenia, Armenia, (2)Hydrometeorology and Monitoring Center SNCO, Republic of Armenia, Armenia*

The sound management of chemicals and waste is essential for protecting human health and the environment. Chemicals play an important role in our everyday lives in materials, articles and products globally. However, when not managed properly they can potentially result in adverse impacts on human health, animals, plants, ecosystems and the environment. The outcome is biodiversity loss, ecosystems degradation, climate change and the emergence and spread of infectious diseases.
For proper management of environment it is necessary to adopt, implement and enforce legal frameworks and established appropriate institutional capacities to prevent or where not feasible, minimize adverse effects from chemicals and waste throughout their life cycle.
For appropriate control it is necessary that comprehensive scientific data and information on the properties of chemicals are generated, made available and accessible for the general public.
It is necessary to give priority to sustainable solutions and safer alternatives to harmful substances in products and mixtures, including in consumer products, in their research and innovation programmes.
In the area of chemicals use it is extremely important to inform end-users, consumers about the properties of chemicals, their health effects towards workers involved in chemicals use and other affected persons. It is necessary to establish requirements by law for labelling of chemicals on the properties and effects to ensure effective awareness about the properties and effects, to reduce the risks.
The objective of environmentally sound management of chemicals is to strengthen existing national structures and mechanisms for coordination for sustainable management of chemicals in an integrated manner that involves all relevant stakeholders in the implementation of the chemicals and waste conventions.
The following priorities should be addressed for making progress: the need for a higher quality of life; a lifecycle approach; a non-toxic environment; a thought set of prevention; no harm to public health; a need to act; safe alternatives and legislation.

6.03.P-Mo465 Translating Lessons Learnt from Communicating Microplastic-Related Research to Chemicals: Making the Invisible Visible

Annika Jahnke *and Dana Kuhnel, Helmholtz Center for Environmental Research (UFZ), Germany*

Every scientist should engage in outreach, to make scientific outcomes more relevant and meaningful, to educate the public, to inform policy-makers and regulators, and to make the use of tax money for research transparent. However, not all scientific topics are easy to communicate to multiple audiences. An example are chemicals and related impacts, which are in many cases invisible to the human eye, complex and intimidating, making related outreach challenging. To the contrary, research and related knowledge regarding plastics have increased tremendously during the last two decades, and so has the related outreach alongside. As a result, any person will with certain likelihood have heard about the related issues and threats. Correspondingly, researchers addressing plastics do not face difficulties in raising interest or setting the scene, whereas their challenges are directed towards conveying the right aspects and dimensions of the problem to correctly inform multiple audiences and give laypersons knowledge and tools required to contribute to achievable solutions and citizen science activities like beach clenups. We have explored multiple ways to convey plastics-related science to fellow scientists, stakeholders, including policy-makers, regulators and non-governmental organizations, and the general public. Those approaches included cover art graphics for scientific journals, interdisciplinary stakeholder workshops from which we conveyed the major outcomes in a science comic designed for primary school children, collaboration with a multidisciplinary artist, support of the design and implementation of workshops for high school students visiting the UFZ Student Lab, contribution of exhibits to the touring exhibition OceanPlasticsLab, a blog, diverse podcasts and multiple interviews for students, newspapers, radio and TV. Here we reflect on how these multiple tools might be modified to effectively convey similar knowledge on chemicals, which are, other than plastic, largely invisible yet surrounding us in a similar way. The related exposure to and hazard of chemicals are well-established, and, last but not least, chemicals and plastics are closely interconnected, which might be a useful link for communication strategies. We particularly reflect on actions directed towards the new global science-policy panel, give an overview and personal assessment in terms of the outreach potential of different means of communication in the context of chemical pollution.

6.03.P-Mo467 Evidence and Insights From Cross-disciplinarians on the New Multi-disciplinary Science Skills and Expertise Needed for the UN Science-Policy Panel on Chemicals, Waste and Pollution Prevention

*Camilla Alexander-White[1], **Frank Adiga**[2], Angeliki Balayannis[3], Chris Barber[4], Natalie Burden[5], Rhys Charles[6], Matthew Davidson[7], Matthew Davies[6], Anthony Gachanja[8], Joshua Kelly[9], Alastair Lewis[10], Yolanda López-Maldonado[11], Catherine Ngila[12], Ovnair Sepai[13], Richard C. Thompson[14], Michael Walker[15], Mengjiao Wang[16], Paul Whaley[17], Christian Zerfass[18] and Tom Welton[19], (1)The Royal Society of Chemistry, United Kingdom, (2)UCL/Amentum, United Kingdom, (3)Wageningen University, Netherlands, (4)Lhasa Limited, United Kingdom, (5)NC3Rs, London, United Kingdom, (6)Swansea University, United Kingdom, (7)Bath Institute of Sustainability and Climate Change, United Kingdom, (8)Jomo Kenyatta University, Kenya, (9)Lamor Corporation (UK) Ltd, United Kingdom, (10)University of York, United Kingdom, (11)Indigenous Science, Mexico, (12)University of Johannesburg, South Africa, (13)Health Security Agency, United Kingdom, (14)University of Plymouth, United Kingdom, (15)The Queen's University of Belfast, United Kingdom, (16)University of Exeter, United Kingdom, (17)Lancaster University, United Kingdom, (18)Friedrich Schiller University, Germany, (19)Imperial College London, United Kingdom*

Modern science is an international and collaborative endeavour. Scientists often work in defined and focused fields of expertise that are very important in providing evidence to inform policy development. Science evidence on the management of chemicals, waste and pollution prevention (CWP) often involves a broad team of multi-disciplinarians. Critical to success is how the new UN science policy panel (SPP) on CWP is assembled following the open-ended working group (OEWG) process, and how the panel accesses multi-disciplinary expertise through cross-disciplinary members of an Interdisciplinary Expert Committee (IEC). Through engagement activities, ongoing focus groups and stakeholder interviews, we share learnings and insights in this presentation, on the breadth of skills and expertise that will be needed by the SPP CWP.

In addition to natural science disciplines of chemistry, biology, physics, earth sciences, engineering, epidemiology, classical toxicology, health sciences, ecology, social, economic and behavioural sciences, risk assessment, also citizen science and indigenous knowledge etc., a plethora of new science disciplines are emerging and developing. For example, advanced materials, artificial intelligence, new approach methods (NAMs, in vitro, organ-on-a-chip and computational methods in toxicological sciences), improved exposure assessment using probabilistic analysis, human/ecological biomonitoring, remediation (bio)technologies, systems biology, new environmental monitoring, life cycle assessment, next generation risk assessment (NGRA) and more. Some scientists are even advocating that in a Chemicals 2.0 vision (in Europe), it is time to bypass the old gold standard methods in regulatory toxicology through a paradigm shift where animal tests are not relied upon. With foresight on the UNEP New Horizons report, we expect the Foundational Document for the SPP CWP to be agreed in OEWG 3.2 in 2025, and that assembling the new panel with the right people round the right tables at the right times will begin in earnest. We advocate developing terms of reference for panel participation that are both inclusive and rigorous in identifying and managing all potential conflicts of interest. In the public interest, all prospective expert participants in the panel must declare transparently all their financial and non-financial interests, for a dedicated committee to review and determine conflicts of interest. Good practice on this will be shared.

Disclaimer/Disclosure: This work is funded by the Royal Society of Chemistry.

6.03.P-Mo468 Bridging the Knowledge Gap on Plastic Pellet Releases: A Case Study in the Port of Antwerp, Belgium

*Ronny Blust[1], Raewyn M. Town[1] and **Hanne Diels**[2], (1)University of Antwerp, Belgium*

Plastic pollution is increasingly threatening ecosystems health. The release of plastics to the environment is linked to various consequences for the living environment and is a major concern for policy makers. The European Commission aims to reduce microplastic releases into the environment by 30% by 2030. A regulation on preventing plastic pellet releases was proposed on October 16th 2023. However, a harmonised methodology for measuring these releases is lacking: although efforts have been made to estimate pellet release, the available data is scarce and not always based on field measurements or observations by independent parties. Bridging this knowledge gap is essential to evaluate the extent of plastic pellet releases worldwide.

We present a case study in the port of Antwerp, a large polymer hub for production, handling and distribution of plastic pellets, located in the Scheldt estuary, northern Belgium. Plastic pellets are being unintentionally released into the environment, finding their way to the Scheldt river. Measures are taken to prevent pellet releases, but the problem is not yet solved.

To identify the current extent of plastic pellet release, 57 locations on the port roads were selected in collaboration with the companies and the port authority, and seasonally monitored using manual sampling with a 50 x 50 cm quadrat. From March 2022 to February 2025, each season 5 samples were taken at each point over 2 weeks. Constructive communication with the companies and the port authority was the key to the establishment of this campaign and provided the opportunity to interact with managers and employees to implement best practices towards zero pellet loss.

Plastic pellet release is ongoing in the entire port area at an average rate of 2.7 to 4.7 plastic pellets per day per m^2. The results show a heterogeneous spatial distribution in the port area, variable over time. A loss of 10.6 tonnes of plastic pellets was calculated in the first year, which increased to 13.9 tonnes in the second year. Preliminary results shows a decrease in pellet release.

This attempt in estimating plastic pellet release by using long-term field measurements is a first step in bridging the knowledge gap on worldwide plastic pellet releases. The easy and feasible methodology provides opportunities to scale up or standardize as insights into the extent of pellet loss are important to provide an estimate of the current and future dynamics of pellets in the harbour and estuary.

6.03.P-Mo469 Can Unintentional Emissions in China Explain the Rapid Rise of Global Atmospheric Contamination with Hexachlorobutadiene?

***Chengkang Chen**[1], Faqiang Zhan[1], Amie Wei[1], Nikolaos Evangeliou[2], Jenny Oh[1], Sabine Eckhardt[2], Minde An[3] and Frank Wania[1], (1)University of Toronto Scarborough, Canada, (2)NILU Norwegian Institute for Air Research, Norway, (3)MIT Massachusetts Institute of Technology, United States*

Hexachlorobuta-1,3-diene (HCBD) was listed in Annex D and E of the Stockholm Convention on Persistent Organic Pollutants (POPs) in 2015 and 2017, respectively, mandating the global reduction of both deliberate and unintentional production. Yet, air-monitoring reveals a continuous and rapid rise in HCBD concentrations from 2008 to 2021, making HCBD one of the most prevalent POPs in the global atmosphere. The observed large scale gradients in atmospheric concentration (China >> Japan > Northern hemisphere > Southern hemisphere), in combination with large emissions of unintentionally produced HCBD reported for the Chinese tri- and perchloroethylene manufacturing sector, led us to hypothesize that Chinese emissions largely explain the observed spatial and temporal atmospheric patterns. We tested this hypothesis with a three-pronged approach, that comprises (i) a compilation of measured data on HCBD in the environment, in particular the derivation of spatial and temporal trends of HCBD in the atmosphere from data generated by a Japanese monitoring program, (ii) use of the Lagrangian atmospheric particle dispersion model FLEXPART to link concentrations measured in Japan to the history of the sampled air masses, specifically with respect to their passing expected HCBD release locations in China, and (iii) use of the Eulerian global, multimedia, time-variant Nested Exposure Model (NEM) to reproduce the observed large scale atmospheric concentration gradients and to inversely constrain time-variant Chinese HCBD emissions. FLEXPARTs identifies Chinese regions with chlorinated solvent manufacturing as making large contributions to the HCBD measured over Japan, whereas NEM succeeds in reproducing the spatial air concentration gradients both between Northern and Southern Japan and between Japan and the rest of the world. NEM simulations further succeed in constraining both the size of the Chinese HCBD emissions over time and the reaction rate constant of HCBD with hydroxyl radicals. Our findings underscore shortcomings in the provisions of Article 5 of the Stockholm Convention in reducing, let alone eliminating, the environmental releases of unintentionally produced POPs, which is particular concerning given that the unintentional production of HCBD during TCE and PCE manufacturing has been known for decades. We discuss the implications for global regulatory frameworks and highlight the urgent need for improved strategies to mitigate unintentional POP emissions.

6.03.P-Mo470 Matrixing of Use Categories and Analysis on Comprehensive Risk Indicator for Each Category

Yoshitaka Imaizumi[1]*, Yosuke Koyama*[1]*, Tomoya Inoue*[2]*, Kohei Iwabuchi*[2] *and Yuki Tamagaki*[2]*, (1)National Institute for Environmental Studies (NIES), Japan, (2)Mizuho Research & Technologies, Ltd., Japan*

The limitations of environmental risk assessment of single chemicals have been pointed out, and discussions for the assessment of multiple chemicals are becoming more active. This is due to a general recognition that a target environment is exposed to various chemicals at the same time. It is also due to the fact that many new chemicals are being developed and manufactured day by day. For exposure assessment in the environmental risk assessment, production volumes (including imports) and emission factors are key information. In order to set emission factors for target chemical substances, information on the way of use is necessary. However, for many chemicals, especially those produced in small volumes, information on the amounts and way of use is not available. The number of the chemicals without information will continue to grow as many regulated and banned chemicals are replaced by more and more substitutions. This study focused on the categorization of use and the comprehensive risk indicators for each category in order to gain an overall picture of the environmental risks posed by chemical substances. This study consists of four steps: 1) reorganization into matrix classification (product use category and functional use category) from the detailed use category (281 category) under the Chemical Substances Control Law (CSCL) of Japan, 2) categorization of chemical substances published under CSCL for the matrixed category, 3) calculation of total production and emission amount of the chemicals under each category, and 4) analysis on comprehensive risk indicators for each category. As a comprehensive risk indicator, we used the ratio of total emissions to the average hazard concentration (HC50) for each category. As a result, several matrixed categories were picked up as higher risk.

Disclaimer/Disclosure: This research was performed by the Environment Research and Technology Development Fund (JPMEERF20225005) of the Environmental Restoration and Conservation Agency provided by Ministry of the Environment of Japan.

6.03.P-Mo471 Hidden in Plain Sight - Solvents Masking Persistent Solutes

Carl Clarke*, Centre for Environment, Fisheries and Aquaculture Science (Cefas), United Kingdom*

Persistence is a one of the key drivers for restricting chemical discharge to the environment. However, examples of substances in solvent (SiS) that are treated as a single chemical have emerged where a readily degradable organic solvent masks the persistency of the solute. Common exemplar chemicals include polymers, plasticisers and resin dispersions and reaction products with dyes suggesting that this topic will resonate across many industries.

Over the last three years, Cefas have managed the phased introduction of the SiS programme under OSPAR agreements on behalf of the UK and Netherlands to address this issue in a regulatory context and contribute to the protection of the North-East Atlantic marine environment.

Cefas observed that studies on SiS frequently demonstrated higher levels of biodegradation than when the solutes were evaluated in isolation, indicating that regulatory data submitted for SiS underestimated the persistence of many chemicals. This has regulatory and environmental implications where the persistence of a chemical is masked by its constituent components, given that persistence is an important criterion for determining whether chemical discharge to the environment should be restricted. Therefore, additional measures are required for substances in solvents to unmask their potential persistency.

This issue was raised at OSPAR s Offshore Industry Committee in 2018, and measures put in place to allow additional biodegradation data for both the solute and the solvent to be gathered from chemical suppliers. Cefas has since undertaken a 3-phase implementation programme, initially targeting high organic solvent content mixtures (?50%) and culminating with substances containing 10-30% solvent in

April 2024. A total of 37 SiS were reviewed with 60% receiving a substitution warning under the UK and Netherlands regimes because of information gathered during the SiS programme. Chemicals in each phase represent approximately one third of the total observed with most suppliers electing to assume zero biodegradation rather than undertake the testing required to obtain better characterisation.

This presentation details the processes undertaken, the impact on regulated chemicals, stakeholder response and practicalities of implementation of the programme. We also highlight the difficulties in this approach and suggest areas for further research and refinement.

6.03.P-Mo472 Overview of Current Key Projects and Research Networks Linking Chemical Pollution and Biodiversity Change in Europe

Francisco Sylvester[1], Sarah Johann[1], Marta Baccaro[2], Steven Brooks[3], Milo Leon de Baat, PhD[4], Valeria Dulio[5], Florian Leese[6], Kari K. Lehtonen[7], Igor Liska[8], Magnus Lofstedt[9], Aourell Mauffret[10], Jannicke Moe[3], Alberto Orgiazzi[11], Luisa Orsini[12], Jaroslav Slobodnik[13], Klement Tockner[14], Lina Wendt-Rasch[15], Jan Koschorreck[16] and ***Henner Hollert**[1]*, *(1)Goethe University Frankfurt, Germany, (2)European Commission, Joint Research Centre (JRC), Italy, (3)Norwegian Institute for Water Research (NIVA), Norway, (4)University of Amsterdam, Netherlands, (5)Ineris, France, (6)University of Duisburg Essen, Germany, (7)Marine and Freshwater Solutions Unit, Finnish Environment Institute (SYKE), Finland, (8)International Commission for the Protection of the Danube River VIC, Austria, (9)European Environment Agency, Denmark, (10)IFREMER, Chemical Contamination of Marine Ecosystems (CCEM), France, (11)European Dynamics c/o European Commission, Joint Research Centre (JRC), Italy, (12)University of Birmingham; Goethe University, United Kingdom, (13)Environmental Institute, Slovakia, (14)Senckenberg Society for Nature Research; Goethe University Frankfurt, Germany, (15)Utveckling\Strategier och uppdrag, Kemikalieinspektionen, Sweden, (16)Umweltbundesamt (UBA), Germany*

Biodiversity loss and chemical pollution are pressing interconnected environmental challenges, yet they are often studied in isolation within distinct subdisciplines. Recent advancements in methods to assess both issues highlight the need for inter- and transdisciplinary collaboration to address their complex interactions.

In December 2023, Goethe University Frankfurt hosted an international workshop, organized by NORMAN, the RobustNature network and the German Environmental Protection Agency to bridge the international NORMAN network with the European biodiversity community. Over 12 keynote speakers and 50 participants from academia and regulatory bodies, including the European Commission s Joint Research Centre, European Environment Agency, European Topic Centre Biodiversity and Ecosystems, and the International Commission for the Protection of the River Danube, informed synthesis discussions on innovative approaches to study the interlinkage between chemical pollution and biodiversity changes.

A survey was conducted among the keynote speakers to examine trends in 13 large European projects and research networks linking chemical pollution and biodiversity changes across terrestrial, marine (50% of projects), and freshwater ecosystems (75%). This selection represents a variety of projects spanning 24 84 months and consortia involving 10 to hundreds of researchers (PIs 33%, PhD 25%, and master s candidates 21%). The projects were predominantly funded by German (36%) and EU (45%) public funding, collectively representing investments exceeding 50 million. Preliminary results indicate that most projects were inter- (64%) or transdisciplinary (18%), focusing on biology, genetics, ecology, biodiversity, ecosystem health, and chemistry (55%), as well as biological and chemical monitoring (45%). Policy and management, ecotoxicology, modeling, and data science were addressed by 18 36% of projects, while other social science disciplines, geography, public outreach, and economics were less frequently included (<10%).

These initiatives integrate innovative chemical and biological approaches to generate interdisciplinary datasets for causation modeling and societal transformation. Detailed analysis of their objectives, methods, and unique contributions will provide a comprehensive overview of state-of-the-art European research networks, regulatory perspectives, and a better understanding of the interlinkage between chemicals and biodiversity in the future.

6.03.P-Mo473 Reevaluating New and Existing Challenges That Early Career Researchers Face Across Regulatory Ecotoxicology

Lowenna Bethany Jones, ***Harry Bond-Taylor****, Susanna Molkanen, Dylan Asbury, Rana Al-jaibachi, Thomas Malpas, Niamh O'Connor, Hana B Mayall and Grzegorz Sylwester Sowa, University of Sheffield,*

United Kingdom
A SETAC Pellston Workshop® on Improving the Usability of Ecotoxicology in Regulatory Decision-Making was held in August 2015. One outcome of the workshop was a publication, which highlighted the challenges ecotoxicologists of the future face in applying academic research to regulatory decision making. The authors propose that training students on issues of relevance and reliability will lead to improvements in the applicability of academic research for regulatory decision making. Whilst also set out the importance of cross-sector partnerships across industry, academia and government. As nearly a decade has passed since the initial workshop, we believe it is important to reevaluate previously identified challenges faced in applying academic research to regulatory decision-making (OBJ1), highlight challenges not previously identified (OBJ2), and assess the uptake of proposed training and skills (OBJ3). To obtain the necessary data a survey was developed and deployed online to gain understanding on the challenges early career researchers (ECRs) face in applying academic research to regulatory decision making, and the training and skills received throughout their career. In total, 52 ECRs responded to the survey. Just over a quarter of respondents (27%) consider themself to be part of a training network, however approximately half of all respondents state that they have received training to understand the regulatory context of their research (52%); ecotoxicology methodologies or guidelines (44%); and principles of quality assurance and good laboratory practice (54%). We explore why ECRs may or may not receive training and assess the extent to which they agree that it has improved the applicability of their research for regulatory decision making. We conclude that whilst some areas of training for ECRs have developed, some areas remain a challenge. These include aspects of interdisciplinary research, cross-sector partnerships, and government or industry participation.

6.04 Methods and Tools Enabling Safe and Sustainable by Design (SSbD) Strategies

6.04.T-01 Hazard Assessment of Safe, Sustainable and Recyclable by Design Polymeric SURPASS Alternatives for Food, Building, and Transport Applications

Ruben Martínez[1]*, Patricia Solorzano*[1]*, Ana Candalija*[1]*, Socorro Vazquez-Campos*[1]*, Thierry Douki*[2]*, Marion Berenguer*[2]*, Jean Breton*[2]*, Josephine Steck*[2]*, Sebastien Artous*[2]*, Manon Bouwmeester*[3]*, Emiel Rorije*[3]*, Ellen Hessel*[3]*, Bas Zoutendijk*[3] *and Yvonne Staal*[3]*, (1)Leitat Technological Center, Spain, (2)Universite Grenoble Alpes, France, (3)Dutch National Institute for Public Health and the Environment (RIVM), Netherlands*
Plastics have become indispensable across many sectors due to their durability and versatility. However, their persistence in the environment poses severe health and ecological risks, as they degrade over centuries, fragmenting into micro- and nano-plastics (MNPs), and leaching toxic additives that pollute ecosystems and potentially disrupt human health. Currently, 70% of plastic waste in Europe is landfilled or incinerated, underscoring the need for safer and more recyclable alternatives.
The SURPASS project addresses this challenge by developing Safe, Sustainable, and Recyclable by Design (SSRbD) polymeric materials. Following the European SSbD framework, the new developed materials focus in three high-demand sectors: a) building (replacing PVC in windows frames by bio-sourced polyurethane resins); b) transport (using lightweight epoxy-vitrimers to replace train metal components); and c) packaging (replacing non-recyclable films by recyclable multinano layered films). These alternatives are intended to reduce environmental impact while meeting industry performance standards.
To ensure the safety of these new developed SSRbD materials, the hazard assessment herein performed included seven endpoints as their cytotoxicity and acute aquatic toxicity, and their potential to exert inflammation, oxidative stress, epigenetic modifications, genotoxicity, and endocrine disruption. All those endpoints measurements were integrated to identify the safest materials among the high priority substances identified according to the different production routes, reference route and SSbD routes: 3 hardeners, 5 different combinations of resins + flame retardant, and leachates extracted from 4 different final composites were assessed in the transport sector. In the case of building sector, 5 different bio-based polyols and 3 catalysts were studied, along with other 5 non-replaceable components. In the case of packaging sector, toxicity of the leachates of 4 multilayered films were studied.
The eco/toxicity of the materials shall be weighed and counterbalanced, allowing the selection of the materials that offer more comprehensive human safety and environmental benefits.
This study is crucial in driving safer and greener innovations in the plastics industry. By rigorously evaluating and advancing less hazardous polymers, the project sets a benchmark for sustainable design, fostering broader adoption of SSRbD principles and supporting a circular economy transition.

Disclaimer/Disclosure: Acknowledgement - This project has received the funding from the European Union s Horizon Europe research and innovation program under grant no. 101057901 Funded by the

European Union. Views and opinions expressed are however those of the author(s) only and do not necessarily reflect those of the European Union. Neither the European Union nor the granting authority can be held responsible for them.

6.04.T-02 Toward a better integration of Risk Assessment and Life Cycle Assessment for Safer and more Sustainable Chemicals

*Serenella Sala[1], Elisabetta Abbate[2] and **Erwan Saouter**[3], (1)EU JRC, Italy, (2)Radboud University, Netherlands, (3)Net-Zero Impact (SAS), France*

The proposed presentation is a contribution toward better integration of chemical hazard data, risk assessment and life cycle assessment under the new EU framework for safe and sustainable by design (SSbD) chemicals. This framework, announced in December 2022, aims to guide the innovation process towards greener and more sustainable chemical usage by minimizing the production and use of hazardous substances. The framework consists of two main phases: the (re-)design phase and the assessment phase, which includes five steps: hazard assessment, worker exposure during production, exposure during use phase and for the environment, life-cycle assessment, and socioeconomic assessment.

The presentation highlights the importance of being consistent in using chemical hazard information generated for CLP and REACH when they are also used in life cycle assessment. The talk will present the development of a new database by the EU JRC to calculate human and aquatic toxicity impact scores using the USEtox model. This database was built using REACH registration dossiers, EFSA data for pesticides and herbicides, and data from the Pesticide Properties Database.

We explain the methodology used to curate data from various databases and the selection criteria applied to ensure the reliability of the data. A new approach based on HC20 (hazard concentration killing 20% of the exposed population) was implemented to calculate freshwater ecotoxicity effect factors. The results showed that the new approach aligns well with official toxicity rankings of substances in EU environmental risk assessment.

In conclusion, the presentation emphasizes the development of a new set of Characterization Factors (CFs) to address the limitations of the USEtox model during the Environmental Footprint pilot phase. These CFs were calculated for all available chemicals, including non-organic substances, using multiple trusted data sources. The article also discusses the open challenges in aligning toxicity-related approaches for Environmental Footprint with risk assessment to ensure the best complementarity and decision-making support for companies.

6.04.T-03 Decision Support System for SSbD of Advanced Nanomaterials

*Susan Dekkers[1], Veronique Adam[2], Veronica Di Battista[3], Wouter Fransman[1], Blanca Suarez Merino[2], Wendel Wohlleben[3], **Hedwig Braakhuis**[4] and Eugene van Someren[1], (1)TNO, Risk Analysis for Prevention, Innovation & Development (RAPID), Netherlands, (2)TEMAS Solutions GmbH, Switzerland, (3)BASF, Germany, (4)National Institute for Public Health and the Environment (RIVM), Netherlands*

To facilitate practical implementation of the Safe and Sustainable by Design (SSbD) approach in industrial innovation processes of advanced nanomaterials, the HARMLESS project developed a Decision Support System (DSS) that considers data availability and resources along the innovation process (https://diamonds.tno.nl/projects/harmlesspublic). The DSS is aligned with the EU framework and recommends the use of tools and methods, including New Approach Methodologies (NAMs) tailored to advanced (nano)materials as well as the innovation stage of the material under development. The HARMLESS DSS includes 3 flexible innovation stages: 1) the ideation and business case phase, 2) the laboratory phase and 3) the pilot phase. Designers are guided through a workflow starting with 3 tools, i.e. AMEA, WASP and ASDI. The Advanced Material Earliest Assessment (AMEA) tool consists of only 3 questions and is used for early categorization and subsequently advice on design principles and applicability of the SSbD approach. If the approach is applicable, the designer is advised to apply the second tool, named Warning flags, design Advice, Screening Priorities (WASP). WASP is based on the AMEA advice and several other existing tools as a simplified approach that requires less information. This approach consists of 12 questions to identify early warning flags on safety and sustainability and to provide design and assessment advice. To help innovators to make a decision on the most optimal SSbD version in the lab phase, another tool, named Alternative SSbD Design Inspector (ASDI) was developed. Based on the early warning flags from WASP, ASDI provides a) guidance on which descriptors to measure and b) insight into the differences between the SSbD versions within the various dimensions (safety, sustainability and performance). More detailed assessment tools, including in vivo hazard prediction methods based on physicochemical and in vitro data are suggested and available in the DSS for the pilot phase. The DSS has been tested and improved with industrial case studies from the HARMLESS project.

Disclaimer/Disclosure: This project has received EU funding from under grant agreement No 953183.

6.04.T-04 Life Cycle Based Risk and Opportunity Mapping: A Systematic Collaborative Procedure to Integrate Environmental and Health in Early Innovation

Therese Karnman[1]*, Steffen Schellenberger*[2]*, Marie Gottfridsson*[1]*, Maja Halling*[1]*, Kristin Johansson*[1]*, Tomas Vilhelm Rydberg*[1] *and Jutta Hildenbrand*[2]*, (1)Swedish Environmental Research Institute (IVL), Sweden, (2)RISE Research Institutes of Sweden, Sweden*

Life cycle-based risk and opportunity mapping (LCBROM) is a qualitative screening approach to investigate potential risk and opportunities in early innovation. The goal is to push the innovation towards a more sustainable solution. This is done using a systematic MET matrix that summarizes aspects of Materials use, Energy consumption and Toxicity issues of each life cycle stage. If LCBROM is used in early innovation of materials or processes, it can reduce the risk of bottlenecks or showstoppers in a later stage of the innovation process.

The LCBROM method is an iterative process and is initiated with a framing of the assessment followed by a start-up meeting. The iterative steps of the method consists of literature reviews (allowing the LCBROM practitioner to collect information to compare the innovation to state-of-art technology) and discussions with relevant stakeholders, with continuous updates and completion of the MET matrix. Depending on whether different aspects are identified as opportunities, risks or areas requiring further investigation, this is colour-coded in the MET matrix to provide a better overview. The collaborative procedure is an important aspect of the LCBROM.

Four LCBROMs has been reported in the research programme Mistra TerraClean: i) Development of a technology to concentrate REEs from water from a discontinued mine; ii) Application of iron sulphide doped activated carbon to remove mercury from a side stream in an enrichment plant; iii) Chemical modification of PEX material to prevent unwanted bacterial growth in the distribution of drinking water; iv) Removal of CO2 from indoor air with filters based on cellulose nano fibrils and activated carbon.

A key learning from the application of the method in the case studies is that it is essential to have a state-of-art benchmark and/or a specific case to relate the innovation to for identifying opportunities. It is, however, not a requirement for risk identification. Another learning is that a formalised stepwise approach and defined input information facilitates the execution of the method. It has also become clear that a mutual understanding of the potential and limitations of the LCBROM method is important to establish early in the assessment.

Beyond Mistra TerraClean, the method will be used in the EU funded research programme BioSustex. It also has the potential to be used in the SSbD framework outlined by JRC.

Disclaimer/Disclosure: Acknowledgement - This project is funded by The Swedish Foundation for Strategic Environmental Research (Mistra), MISTRA TerraClean (project no. 2015/31) and BioSusTex (GRANT agreement number 101135372)

6.04.T-05 MechoA+: One Scheme to Bind Them All

Gaspard Levet[1]*, Franklin Bauer*[1]*, James Firman*[2]*, Homa Basiri*[2]*, Bruno Campos*[3]*, Jayne Roberts*[3]*, Paul Thomas*[1]*, Mark Cronin*[2] *and Geoff Hodges*[3]*, (1)KREATiS, France, (2)Liverpool John Moores University, United Kingdom, (3)Unilever, United Kingdom,*

The rise in interest for new approach methodologies (NAMs) has led to the development of a wide range of in silico approaches. Among them, KREATiS, Liverpool John Moores University (LJMU) and Unilever SEAC recently developed the MechoA+ scheme, by integrating and further refining the MechoA and Sapounidou-Firman schemes into one unique scheme. This tool is designed to help comprehend the mechanisms of toxic action related to chemical substances. It detects if the substance has a structural pattern known to be related to particular MIE(s) and for which species. Thus, it gives useful information for forecasting, controlling, and reducing the effects of chemicals on both human health and the environment as requested for SSbD assessment.
The new in silico profiler is organised by molecular initiating events (MIEs) which are the first key events in Adverse Outcome Pathways (AOPs). Each mechanism is supported by (eco)toxicological data/

knowledge from the literature. The domain of each alert of the profiler has been defined in terms of structural features responsible for the MIE and species affected. In total there are more than 150 structural alerts for various MIEs. MechoA+ alerts have been coded into iSafeRat® Desktop, providing the basic requirements for allocating a chemical to mechanistically-related QSARs. It is also being coded as a new profiler for the OECD QSAR Toolbox. In order to test the relevance of the new scheme coded in MechoA+, the SMILES strings of over 70,000 structures were screened by MechoA+ and a comparison with results from the previous MechoA and Sapounidou-Firman schemes was undertaken.
The new MechoA+ scheme shows excellent coverage, with very few compounds unassigned, and a good accuracy compared to the mechanisms inferred from literature analysis. The evaluation demonstrates the comprehensive utility of the MechoA+ scheme, while also identifying some specific areas of chemistry where mechanistic assignment is currently lacking. In particular a need was identified to create further alerts for endocrine disruption.
In most cases, the results from the new scheme complements and enhances the previous schemes with additional knowledge (e.g., species applicability, specific target hit, further key events, etc.), enhancing its usefulness for hazard assessment and understanding as well as confidence in the prediction.

6.04.P Methods and Tools Enabling Safe and Sustainable by Design (SSbD) Strategies

6.04.P-We483 Towards a Flexible, Solution-Oriented SSbD Framework in Industry: A Practical Case Study

Karoline Wowra[1]*, Athanasios Gkrillas*[2]*, Winfried Bulach*[1]*, Alexandra Gastens*[1]*, Lidia Ceriani*[3]*, Erwan Saouter*[4] *and Florian Gruener*[1]*, (1)Merck Life Science KGaA, Germany, (2)Merck Life Science BV, Belgium, (3)Merck Life Science Srl, Italy, (4)Net-Zero Impact (SAS), France*

The European Union's Chemicals Strategy for Sustainability (CSS) emphasizes a toxic-free environment. The "Safe and Sustainable by Design" (SSbD) framework plays a critical role in assessing the safety, environmental, and socio-economic sustainability of chemicals and materials. This study presents a simplified SSbD assessment applied to two detergents used in biomanufacturing. One detergent is classified as a substance of very high concern (SVHC) due to the endocrine-disrupting properties of its degradation product, while the second is a readily biodegradable alcohol ethoxylate.
We conducted a human health and environmental risk assessment coupled with a Life Cycle Assessment (LCA), i.e., Steps 1 to 4 of the SSbD, to evaluate the detergents' safety and performance across various disposal scenarios, including incineration and wastewater treatment. The functional unit was defined as 1 kg of detergent for virus inactivation, and a cradle-to-grave assessment was performed. The overall assessment utilized several (Q)SAR and exposure assessment tools, coupled with different LCA databases, and utilized AI-based models to fill data gaps. The score drivers were significantly influenced by both the classification of the first product as SVHC and environmental Risk Characterization Ratios (RCRs) during industrial manufacturing and use. On the contrary, the second product demonstrated advantages in terms of sustainability metrics, particularly in climate change and resource use (fossil).
Challenges encountered included the identification of protective toxicological endpoints for Derived No-Effect Level (DNEL) derivation and the acquisition of tonnage information from both upstream and downstream sources. Additionally, data availability from suppliers hindered comprehensive data acquisition.
Our findings advocate for a pragmatic, stepwise SSbD application, particularly for low-volume, low-hazard chemicals, enabling a more manageable integration of safety and sustainability assessments. This case study demonstrates the potential of the SSbD framework to improve chemical safety and environmental sustainability in the Life Science sector while also tackling the complexities associated with data requirements and model integration. A step forward to assist SSbD practitioners in data filling will be the acceptance of e.g., Integrated Approaches to Testing and Assessment (IATAs), and New Approach Methodologies (NAMs) for higher-tier endpoints.

6.04.P-We484 Safe and Sustainable by Design and Circularity Operationalization Via Multiple Criteria Decision Analysis

Marco Cinelli[1]*, Ana Arias Calvo*[1]*, Maria Teresa Moreira*[2] *and Stefano Cucurachi*[1]*, (1)Institute of Environmental Sciences (CML), Leiden University, Netherlands, (2)CRETUS, Department of Chemical Engineering, School of Engineering, University of Santiago de Compostela, Spain*

The Safe-and-Sustainable-by-Design (SSbD) framework of the European Commission (EC) was introduced in 2022, and its related methodological guidance as well as its application to case studies have also been recently published. The wide set of indicators that characterize the EC-SSbD framework can raise the challenge of performing trade-offs among the indicators to comprehensively evaluate the chemical or material under study. To aid this complex process, Multiple Criteria Decision Analysis

(MCDA) has been proposed as a promising methodological solution, with close to 30 studies already combining safety and sustainability. However, until now, there was no SSbD-based solution using MCDA where it is possible, at the same time, to (i) apply the framework with only one alternative, as well as with more than one, (ii) test the effect of different compensation levels on the final decision recommendation, and (iii) include circularity indicators too. To fill this gap, using an MCDA method, we propose a new composite indicator (CI) to operationalize the EC-SSbD framework. It is called CI-SSbDC and a stepwise procedure is proposed to apply our index. It includes (i) safety, life cycle sustainability and circularity assessment using five dimensions, namely hazard dimension , health dimension , environmental dimension , circular dimension , and economic dimension , and (ii) aggregation of the information to provide a score between 0.01 and 1 that characterises the overall performance of the alternatives. We tested the CI-SSbDC in three case studies, using bio-based waste streams to produce nisin. The index showed the capability of the proposed methodology to effectively deal with the underlying 26 indicators, while still providing a final comprehensive trend in the performance of the alternatives, which enables more informed decision-making. The CI-SSbDC can thus be used by process developers who are interested in comprehensively evaluating the safety, sustainability, and circularity of products at an early development stage. It suits well users that want to visualise the overall performance of products, as well as identify hotspots during their life cycle. A key novelty of this work in this area consists in the use of a MCDA method that allows to harmonize all the impact and benefit values on a common scale. In addition, it accommodates decision-makers with different preference structures, from weak to strong concepts of sustainability.

6.04.P-We485 Testing and Demonstration of the Applicability of the SSbD Framework to Develop Innovative Chemicals and Materials for replacing SVHC in High-impact Markets
Arantxa Ballesteros Riaza *and Carlos Fito, ITENE, Spain*
The growing safety and sustainability requirements for substances and materials, as well as current and future restrictions established in the European Regulation, have driven an escalating demand for alternatives in the chemical sector, especially for those applications where potentially hazardous substances classified in one of the ECHA hazard categories are used or developed, such as substances of concern (SoC) and substances of very high concern (SVHC). In this context, the Chemicals Strategy for Sustainability (CSS) is a key step towards achieving a zero-pollution and toxic-free environment, aiming to position the EU as a global leader in producing safe and sustainable products by design (SSbD). The holistic approach considered by EC-JRC within the SSbD framework is needed for the promotion of the assessment and substitution of hazardous substances.
In this context, the main goal of the AlChemiSSts project is to test and demonstrate the applicability of the SSbD framework to develop innovative chemicals or materials to replace SVHC in high-impact markets, notably for surfactants, plasticizers, and flame retardants in relevant value chains, including metal working fluids (MWFs), lubricants, insulation foams and paints, safety boots and wellies, battery cases and sports mats. For that, a suite of case studies including relevant actors in each value chain is being conducted to generate scientific and technical driven evidence Proof of Concept of the applicability of the SSbD framework to develop alternative substances and materials with proven safety and sustainability, able to replace existing substances of concern, as well is to identify and define specific recommendations and elements to be considered for the further refinement of the SSbD framework.
AlChemiSSts deals with the design and development of new substances and materials to be used as surfactants, flame retardants and plasticizers substitutes in real industrial applications. The project is working on the identification of the barriers to enable the implementation of the SSbD framework at all stages of the life cycle for targeted substances, materials and applications including: new approach methodologies (NAMs), data/knowledge barriers, exposure scenarios and risk assessment in processes, sustainability assessment (LCA and SEA), and definition and communication of proposed solutions and recommendations to foster and incentive the application of the SSbD framework.

Disclaimer/Disclosure: Acknowledgement
AlchemiSSts (Alternative Chemicals and Materials integrating Safety, Sustainability, new Production technologies and Socio-economic aspects) is a Project funded by the European Union, within the Horizon Europe Programme for Research and Innovation, under the Grant Agreement N° 101178074.

6.04.P-We486 The MAUT Approach for the Evaluation and Comparison of Functional Alternatives: A Case Study on Fluorinated Gases Used in Insulation Materials
Romain Figuière[1]*, Rahul Aggarwal*[2]*, Olivier Kirik*[3]*, Gregory Peters*[2] *and Ian Cousins*[1]*, (1)Stockholm University, Sweden, (2)Chalmers University of Technology, Sweden, (3)AgroParisTech, France*
Although the elimination of substances of concern is the most effective measure to decrease the risk they

represent, a careful evaluation of potential alternatives is needed to prevent regrettable substitution from happening. To that end, different alternatives assessment frameworks were developed in order to identify, evaluate, compare, and select safer alternatives to a chemical of concern. However, recently it has been demonstrated that more research is still needed to ensure proper implementation of those frameworks, and efforts are especially needed to advance and incorporate flexible and practical approaches for trade-off considerations in decision-making. Multicriteria decision analysis (MCDA) methods, including the multi attribute utility theory (MAUT) approach, were suggested to face these challenges. By taking the example of fluorinated gases used as foam blowing agents in insulation materials, this study aims to propose a method based on the MAUT approach to compare functional alternatives to a chemical of concern based on their environmental impacts along their life cycle, and their technical performance. The functional substitution approach was followed to define the functions delivered by fluorinated gases in insulation materials, and the ZeroPM alternatives database was used to identify functional alternatives. Data on environmental impacts along the life cycle, and the technical performance of the identified alternatives were collected based on previous literature reviews on insulation materials. The data were complemented by a semi structured literature search when necessary. The MAUT approach was used to compare the different alternatives. Different decision-making scenarios were defined in order to illustrate the flexibility of the MAUT method for the assessment of functional alternatives. Overall, 9 alternatives to polyethene foams and extruded polystyrene foams containing fluorinated gases were identified. 7 materials could be considered as more sustainable based on their environmental impacts along their life cycle compared to the insulation foams containing the fluorinated gases. When considering technical performance in addition to the environmental impacts in decision-making, one insulation material was identified as a suitable alternative, which suggests that the use of fluorinated gases in insulation materials can be phased-out.

6.04.P-We487 Addressing Data Gaps for Safe and Sustainable by Design: A Substance-Use Dataset to inform on Functional Alternatives for PMT/vPvM Chemicals

Bianca Stadelmann[1]*, Milo Leon de Baat, PhD*[1]*, Antonia Praetorius*[1]*, Agnes G. Oomen*[2] *and Annemarie van Wezel*[1]*, (1)Institute for Biodiversity and Ecosystem Dynamics, University of Amsterdam, Netherlands, (2)National Institute for Public Health and the Environment (RIVM), Netherlands*

Persistent, mobile and toxic (PMT) as well as very persistent and very mobile (vPvM) pose a threat to drinking water quality and ecosystem health. PMT/vPvM substances do not readily degrade in the environment, can travel large distances and are difficult to remove with current water treatment technologies. PMT chemicals also exhibit toxicity to humans and biota. Hence, there is an urgent need to phase out these hazardous substances. An efficient process to identify functional, safe and sustainable by design (SSbD) alternatives is critical to achieving this. However, the scattered and rather generic nature of knowledge of the specific substance-use combinations for PMT/vPvM chemicals is a major barrier to assessing the suitability of potential alternative substances.

The research presented in this poster aims to address this challenge by manually compiling a high-quality dataset of substance-use combinations for a defined group of high-volume PMT/vPvM substances registered under REACH. Use categories, key functions and properties of each chemical and fundamental to the uses are extracted from databases, such as the substances in preparations in Nordic countries (SPIN), as well as patent literature and systematically catalogued. This allows for additional evaluation of the necessity of P, M and T properties for individual uses and informs future SSbD assessments of potential functional alternatives. This approach, targeting specifically the high-volume PMT/vPvM chemicals, allows for an in-depth assessment of all relevant substance-use combinations, enabling better evaluations of alternatives at early data-poor stages of the innovation process.

This substance-use dataset provides a critical foundation for developing and applying quantitative structure-use relationships (QSURs) to support targeted design workflows. Additionally, this dataset can facilitate the development of machine learning and artificial intelligence approaches, assisting in the knowledge collection of additional substance-use combinations. Ultimately, the compiled dataset provides a basis for allowing innovators to rapidly identify high-potential functional SSbD alternatives for further evaluation, accelerating the transition away from hazardous chemicals.

6.04.P-We488 Approaches for Safety Assessment and Sustainability of rPEX and Its Additives From Early Stages: Development of Methods and Tools to Implement the SSbD Framework

Pau Camilleri*, Javier Alcodori, María Rivero García and Arantxa Ballesteros Riaza, ITENE - Instituto Tecnologico del Embalaje, Transporte y Logistica, Spain*

Polyethylene is the most widely used plastic. Cross-linked PE (PEX) exhibits significantly improved properties, notably in terms of thermal stability, chemical resistance and structural integrity. As a result of

cross-linking, PEX is used in a number of applications for which PE naturally lacks required properties, or replacing potentially toxic materials, such as poly(vinyl chloride). However, due to the existence of cross-links, PEX cannot be melted and recycled/reused and is generally downcycled as a filler in other thermoplastic blends with poor mechanical properties.
To address these challenges, REDONDO project develops and applies Safe-and Sustainable-by-Design (SSbD) principles in rPEX (Reversibly PEX) and its additives design process to reduce their environmental impact and promote the design materials with these principles in early stages, by defining and assessing criteria regarding safety and sustainability of rPEX (and its additives). The results obtained from the implementation and evaluation of SSbD are being incorporated into the development of REDONDO, a digital toolbox that will support decision making for formulators and industry, guiding the development of safe and sustainable application of rPEX.
For the SSbD assessment, a tiered approach has been followed, including safety and sustainability assessment. To ensure safety, a risk assessment is carried out, involving in vitro toxicological studies based on OECD protocols, as well as an occupational exposure assessment through monitoring campaigns. To guarantee sustainability, a life cycle assessment (LCA) is implemented to identify the key hotspots for environmental improvement from the design stage in the polymer formulation process to final products. Life cycle cost (LCC) assessment has also been performed to estimate the costs of the different demonstrators to help make a more informed decision when selecting the most sustainable and viable processes and products for the scaling up.
This tier-approach is not only been carried out to assess the effects of the new polymers on humans but also plays a key role in the modification of the rPEX following SSbD strategies to obtain safer and more sustainable polymers with a reduced impact on health and the environment. The experience gained from implementing and developing strategies in the polymer sector will advance the understanding of how to move towards a greener transition in line with the Chemicals Strategy for Sustainability (CSS).

6.04.P-We489 The SAbyNA Platform: A Guidance Tool to Support Industry in the Implementation of Safe and Sustainable by Design Concept for Nanomaterials, Processes and Nano-enabled products

Virginia Cazzagon[1], Ralph Vanhauten[2], James Hanlon[3], Hedwig Braakhuis[4], Matthew Boyles[3], Ana Candalija[1], Felice Carlo Simeone[5], Richard Seddon[6], Leire Barruetabena[7], Lion Traas[2], Davide Lotti[8] and ***Socorro Vazquez-Campos**[1]*, *(1)Leitat Technological Center, Spain, (2)ThinkWorks, Netherlands, (3)Institute of Occupational Medicine (IOM), United Kingdom, (4)National Institute for Public Health and the Environment (RIVM), Netherlands, (5)CNR-ISSMC-Institute for Science, Technology, and Sustainability of Ceramics, Italy, (6)TECNALIA Research and Innovation, Donostia-San Sebastian, Spain, (7)GAIKER Technology Centre, Spain, (8)LATI Industria Termoplastici S.p.A., Vedano Olona, Italy*

The implementation of Safe and Sustainable by Design (SSbD) strategies for materials and products is essential to achieve the Zero-Pollution Ambition stated in the EU Green Deal. Simple, cost effective and reliable methods are needed for pragmatic and flexible evaluation of safety and sustainability at early stages of innovation, especially for nanoforms and nano-enabled products, for which validated guidelines for the assessment and management of safety and sustainability are still lacking. The SAbyNA Platform has been developed by making use of existing resources that guide decisions to ensure safety and sustainability of nanoforms and nano-enabled products at the design stage of product development. Key resources from previous EU projects such as GUIDEnano (G.A. 604387) and GRACIOUS (G.A. 760840) were used. In addition, the project responded to the needs of stakeholder profiles (i.e., industry, consultants, RTOs, regulatory bodies) on how to implement SSbD through continuous stakeholder engagement. The ability of this tool to support the design of safer and/or more sustainable nano-enabled products is demonstrated through the implementation of the SAbyNA Guidance Platform in real-world case studies, such as nano-enabled 3D-printed vacuum cleaner components with antistatic properties, made with polycarbonate and single walled carbon nanotubes. The SAbyNA Platform consists of four informative modules intended to provide information to the user on the methods, models and tools suggested for exposure and hazard assessment and on Safe-by-Design interventions, and two assessments modules to conduct a screening life cycle and cost assessment, as well as a safety assessment of nanoforms and nano-enabled products. Once screening data on the additive manufacturing case study were

added, Safe-by-Design recommendations were provided, such as by reducing fiber length or rigidity or by changing the form of the NFs (e.g., using pellets/granules instead of NFs in powder form). Hazard, exposure, costs, sustainability and functionality data of the assessed case study were added in the Platform to define whether (or not) the implemented Safe-by-Design intervention was able to increase the safety of this nano-enabled product.

The authors thank the work performed by all the project partners in the development of this tool.

6.04.P-We490 Integrated SURPASS Scoring System for Safe, Sustainable and Recyclable by Design Assessment

Camilla Delpivo[1], Virginia Cazzagon[1], Josephine Steck[2], Stephanie Desrousseaux[2], Sebastien ARTOUS[2], Yvonne Staal[3], Daniel Ganszky[4], ***Socorro Vazquez-Campos[1]*** *and Simon Clavaguera[2], (1)LEITAT Technological Center, C/ de la Innovacio, Spain, (2)Univ. Grenoble Alpes, CEA, Liten, France, (3)Dutch National Institute for Public Health and the Environment (RIVM), Netherlands, (4)Geonardo Ltd, Hungary*

EU is promoting different strategies such as the Chemicals Strategy for Sustainability and the zero-pollution ambition of the European Green Deal, to facilitate the industrial transition towards a safe, zero pollution, climate-neutral and resource-efficient production and consumption, addressing adverse effects on humans, ecosystems and biodiversity from a lifecycle perspective. In this context, the European Commission recommendation was establishing an assessment framework, promoting research and innovation for safe and sustainable by design (SSbD) chemicals and materials and the EU Joint Research Centre published different documents to guide in the implementation of the SSbD framework.
One of the main challenges of the SSbD framework concerns difficulties in implementing the steps of the assessment along the innovation process. The project SURPASS aims to deliver a web-based digital infrastructure to guide SMEs towards the development of Safe-, Sustainable-, and Recyclable-by-Design (SSRbD) polymeric materials, providing tools, methods and data to support the implementation of the assessment steps described in the framework.
Moreover, SURPASS addresses a crucial aspect of the SSbD Framework implementation, which is the integrated and overall assessment of the SSRbD steps of hazard (Step1), exposure and release (Steps 2 and 3), life-cycle and life-cycle costing (Steps 4 and 5) assessments. This was done by developing individual scoring systems for each step. Each individual scoring was based on specific score pillars that were combined to provide assessment step scores, that were then integrated to provide a final unique SSRbD score. This scoring strategy complements the assessment steps and do not aim to replace their conclusions and results. Instead, it provides a visual overview of their outcomes indicating improvements and degradations of different types of material or product performance (e.g., hazard, release, sustainability, etc.).
The final and unique SSRbD score summarizes, but at the same time hides , in one unique value all the information from the previous assessment. Therefore, it should be considered together with all the previous assessment scores and pillar scores, that allow the users to understand which aspect of the SSRbD alternative can be improved or further investigated.
This work is meant to underpin the innovation process, supporting the SSRbD approach by facilitating the decision-making process.

Views and opinions expressed are however those of the authors(s) only and do not necessarily reflect those of the European Union. Neither the European Union nor the granting authority can be held responsible for them. The authors thank all WP4 and WP5 partners for contributing to the development of the integrated scoring system.

6.04.P-We491 Workflow and Overall Structure of an SSbD Digital Infrastructure for SME and Polymeric Materials

Josephine Steck[1]*, Stephanie Desrousseaux[1], Sebastien Artous[1], Lya G. Soeteman-Hernandez[2], Yvonne Staal[2], Virginia Cazzagon[3], Camilla Delpivo[3], Daniel Ganszky[4] and Bese Pal[4], (1)Univ. Grenoble Alpes, CEA, Liten, France, (2)Dutch National Institute for Public Health and the Environment (RIVM), Netherlands, (3)Leitat Technological Center (HEHS Area), Spain, (4)Geonardo Environmental*

Technologies Ltd., Hungary
Previous and current projects indicate that many resources (data, tools, methods) are available for the risk and sustainability assessment of materials. However, these resources are not suitable for safe and sustainable by design (SSbD) implementation by small and medium enterprises (SME) as they are quite complex, require a lot of data, are time-consuming and are not always material specific. SMEs need a clear guidance on how to make their materials, products or processes safer and more sustainable. In order to support the development of SSbD polymeric materials, a web-based digital infrastructure was developed which follows the Joint Research Center SSbD framework.
The main goal of this infrastructure is to support SMEs to implement SSbD in their materials design by integrating tools and data to drive better decision-making that aligns with environmental and economic sustainability while ensuring material safety. This infrastructure consists of a four-tiered workflow to give users SSbD options based on limited data.
First, the infrastructure has an SSbD e-learning module designed to provide in-depth knowledge and practical insights into sustainable, recyclable materials and technologies across various industries.
Second, guiding principles are provided to support the design of chemicals and materials. The (re) design and SSbD leverage identification is the first phase of the two-phase approach recommended in the SSbD framework. Criteria are defined and detailed to guide the users through the (re)-design phase of the SSbD innovation. The users will then be able to reproduce the same approach as the case studies presented as examples.
Third, the assessment methodology is a step-wise tiered and iterative approach addressing hazard, exposure, environmental, economic and social impacts and providing a unique scoring strategy. Assessment needs depend on the process maturity and three tiers are offered. This is the second phase of the SSbD framework.
Finally, the infrastructure provides access to all the project public results with a permanent access to the entire scientific outcome.
This work is developed within the framework of polymer substances and their additives (including end-of-life recycling). However, this approach can be extrapolated to other substance families.

Disclaimer/Disclosure: Project funded by the European Union under the Horizon Europe work programme grant agreement N 101057901. Views and opinions expressed are however those of the authors(s) only and do not necessarily reflect those of the European Union. Neither the European Union nor the granting authority can be held responsible for them. The authors thank all WP4 and WP5 partners for contributing to the development of the workflow.

6.04.P-We492 Tier 1a SSbD Methodology for a Preliminary Assessment Developed within SUNRISE Project

***Arianna Livieri**[1], Gloria Fortin[1], Lisa Pizzol[2], Sarah Devecchi[2], Alex Zabeo[2], Elena Semenzin[1] and Danail Hristozov[3], (1)Ca' Foscari University of Venice, Italy, (2)GreenDecision S.r.l., Italy, (3)Emerge, Bulgaria*
The policy objectives of the European Green Deal, as outlined in the Chemicals Strategy for Sustainability and the Zero Pollution Action Plan, emphasize the critical need for adopting a Safe and Sustainable by Design (SSbD) approach for chemicals and materials. To drive this transformation, the European Commission (EC) has recommended creating a European assessment framework for SSbD of chemicals and materials, based on a holistic approach developed by the EC's Joint Research Centre.To aid stakeholders, particularly within the industry, in practically implementing the EC-JRC framework, the Horizon Europe SUNRISE project is developing an Integrated Impact Assessment Framework (IIAF). This framework aims to assess the health, environmental, social, and economic impacts of products enabled by advanced materials (AdMa). The IIAF, aligned with the EC-JRC SSbD framework, follows a 3-tiered approach, with each tier offering an integrated methodology supported by a dedicated toolbox for assessing various impacts. These tiers target different user groups at various stages of the innovation process, with the first tier divided into two sub-tiers: Tier 1a and Tier 1b.This presentation focuses on the development of Tier 1a, a rapid screening method based on a 20-question questionnaire designed to assess safety and sustainability aspects in the early design stage.To develop Tier 1a, a thorough review of existing approaches, frameworks, and questionnaires was conducted to assess safety, sustainability, functionality, and regulatory aspects. The aim was to identify commonalities, especially the frequently repeated and important questions. Subsequently, a preliminary set of questions was created in collaboration with key stakeholders from industry, regulatory bodies, policy-making, and academia. A working group of experts in SSbD frameworks, nanomaterials risk assessment from various EU projects, and environmental and socio-economic sustainability was formed. This group meets periodically to design the questionnaire and determine the most relevant questions.

6.04.P-We493 Safe and Sustainable Bio-Design of Polymers for a Circular Economy

*Jose Jorge Esp Gallart[1], David Sanchez Domene[1], **Laura Mayor Perez**[1], Mireia Mesas[2] and Hector de Buen Lapena[2], (1)Eurecat, Centre Tecnol gic de Catalunya. Waste, Energy and Environmental Impact Unit, Spain, (2)Eurecat, Centre Tecnol gic de Catalunya. Water, Air and Soil Unit, Spain*

The transition toward biobased polymers derived from second-generation (2G) feedstocks, such as agri-food waste and biomass, presents a critical opportunity to enhance sustainability and reduce dependency on fossil-based materials without affecting timber, food and other sectors. To ensure these materials meet stringent safety and sustainability criteria, the Safe and Sustainable by Design (SSbD) framework seems to be an exceptional tool to be applied. Prioritizing safety and sustainability throughout the entire life cycle of bio-based chemicals, ingredients and materials represents a paradigm shift in improving not only their sustainability profile, but other well recognized challenges in bio-based sector: raw material availability, high production costs, lack of infrastructure, complex regulations, consumer acceptance, competition with fossil-based products and scalability issues.

The present work, developed within the framework of the POLYMERS-5B project, details how all these kind of materials, including polyesters, polyamides, polyphenols, and poly-furans, are designed following SSbD metrics to mimic the properties of fossil-based polymers, such as PET and PUs, while delivering improved biodegradability and circularity and adresses all these challenges. By leveraging biocatalysis and green chemistry, these materials achieve high functionality and performance, making them suitable for applications in textiles, automotive, and furniture.

A detailed weighting system to determine score of SSbD following all these statements as well as safety and sustainability considerations are embeded in early design process. Thanks to that, innovation can advance for the development of bio-based materials that support the circular economy, providing environmental benefits while meeting market and performance demands. System allows to integrate ecodesign principles, lifecycle thinking and the reduction of chemical toxicity and risks for human health and the environment, ensuring that these solutions enhance safety and sustainability without compromising other dimensions, such as performance or economic viability. This iterative and quantitative approach, applied from the earliest stages of innovation is crucial for addressing global challenges like resource efficiency, carbon reduction, sustainability and minimizing chemical hazards.

6.04.P-We494 An Overview of the Methodology and Implementation of the Step 1 of the EC SSbD Framework for the Development of Safe and Sustainable by Design Graphene/Mxenes Hybrids

*Julia Rodriguez Vinagre[1], Sonia Martel-Martin[1], Carlos A Rumbo[1], Rocio Barros[1], Santiago Aparicio[1], Sergio de la Huerta[1], Javier Alcodori[2], Arantxa Ballesteros Riaza[2], Carla F. Martins[3], Ana Rita S. Alberto[3], Joao Laranjeiraa[3] and **Laura Gomez-Cuadrado**[1], (1)International Research Centre in Critical Raw Materials-ICCRAM, Universidad de Burgos, Spain, (2)Processes and Products Safety Unit. Technological Institute of Packaging, Transport and Logistics (ITENE), Spain, (3)ISQ Instituto de Soldadura e Qualidade, Portugal*

The SAFARI project advances the development of MXenes, 2D materials derived from MAX phases, known for their high electrical conductivity, mechanical strength, and chemical stability. These qualities make MXenes promising for industrial applications, including conductive inks, biosensors, and electromagnetic shielding paints. However, current production methods often rely on hazardous chemicals, raising human and environmental safety concerns. The project adopts Safe and Sustainable-by-Design (SSbD) principles, utilizing REACH-compliant chemicals and conducting thorough safety and sustainability assessments for MXenes and hybrid MXenes with graphene.

The implementation of Step 1 of the SSbD framework focuses on analyzing the intrinsic hazards of materials. A hazard pre-assessment classified materials using data from the European Chemicals Agency (ECHA) database, including classifications of Substances of Very High Concern (SVHC) and REACH-restricted substances.

A decision tree was developed to guide subsequent actions based on the registration status of materials. For unregistered materials, in vitro toxicity tests will assess human and environmental hazards. For registered materials, hazard evaluations occur in three stages: Stage 1 utilizes ECHA CL inventory data; Stage 2 addresses data gaps with QSAR models like VEGA, QSAR Toolbox, and EPI Suite, as well as prediction tools and literature reviews; Stage 3 identifies hazard classes not applicable under European regulations and those lacking sufficient data.

Challenges emerged, such as limited QSAR model capabilities and low reliability in some cases. Additionally, newer toxicological categories like Endocrine Disruption (ED), Persistent Bioaccumulative and Toxic (PBT), and Persistent Mobile and Toxic (PMT) lack robust data, complicating accurate classification.

The decision support tree and strategies for addressing data gaps enable more comprehensive Step 1 implementation within the SSbD framework. After completing hazard evaluations, levels were assigned, and a final score determined material suitability. This score identifies substances requiring replacement, those necessitating safety measures, and those safe for use. Alongside subsequent SSbD steps, it informs material development, exposure assessments, and sustainable scaling of production processes, reducin g hazards, risks, and environmental impacts.

Disclaimer/Disclosure: This study has received funding from the European Union s Horizon Europe program (SAFARI, Grant Agreement no 101135965).

6.04.P-We495 Probabilistic Multi-perspective Application Selection for Safe and Sustainable-by-Design: A Case Study on Biochar

Akshat Sudheshwar, *Zhaniya Mukhamadiyeva, Nadia Ilaria Malinverno, Claudia Som, Roland Hischier and Bernd Nowack, EMPA - Swiss Federal Laboratories for Materials Science and Technology, Switzerland*

Here, we propose the Probabilistic Multi-perspective Application Selection (pMPAS) to identify Safe and Sustainable-by-Design (SSbD) applications for novel materials. Although not a novel material, biochar has been selected as the subject of this pMPAS case study because its growing prominence as Negative Emissions Technology (NET) is also fostering novel applications. Novel biochar applications aim for extended carbon storage (particularly for low-quality biochars that degrade faster) by prolonging biochar's use phase, delaying its environmental release, and consequent degradation. Nevertheless, an SSbD assessment for novel biochar applications is necessary to under-stand and balance trade-offs between NET and toxicity concerns (from heavy metals, polycyclic aromatic hydro-carbons, etc.). Therefore, this pMPAS case study stochastically scores the functionality, (human and environmental) safety, (environmental) sustainability, and economics of 15 novel biochar for an SSbD ranking wherein Animal Feed, Passive Cooling, and Concrete Aggregates rank the highest, whereas Reductants, Plastic Additives, and Car-bon Nanomaterials rank the lowest.

Keywords: Biochar, Negative Emissions Technology (NET), Safe and Sustainable-by-Design (SSbD), Probabilistic Multi-perspective Application Selection (pMPAS)

6.04.P-We496 Streamlining Safe and Sustainable by Design Practices: A Knowledge-integrated Toolbox and Workflow Approach supporting Innovative and Safer Product Design

*Indre Piragyte-Langa Oliva, Ghada Tagorti, Pascal Ankli, Andrii Milovich, Daniel Burgwinkel and **Barry Hardy**, Edelweiss Connect GmbH, Switzerland*

This presentation will emphasise the incorporation of Safe and Sustainable by Design (SSbD) principles into the development of new products. Traditional product safety assessment processes frequently rely on lengthy animal testing and may fail to accurately predict and manage impacts on human and environmental health and their interactions, highlighting the urgent need for a move toward more ethical and comprehensive assessment methods. Within our framework, New Approach Methods (NAMs), such as high-throughput screening, in silico and in vitro methods, and omics technologies, are integrated into tiered strategies such as Integrated Approaches to Testing and Assessment (IATA), Next Generation Risk Assessment (NGRA), and SSbD to incorporate safety and sustainability into product design from the start of the innovation and development process.

Our developed toolbox includes a variety of tools, guidance manuals, databases created using harmonised data templates for collected data and data generated and managed following FAIR principles, incorporated into a workflow system implementing SSbD tasks and decisions. The toolbox is designed to assist product designers, innovators and risk assessors by incorporating safety and sustainability considerations into the product and process lifecycles from early innovation stages. We will specifically detail how we are creating a workflow system that allows users to use this toolbox effectively, hence improving their ab ility to integrate the concepts and calculations into daily operations and decisions.

Through application to a variety of industrial case studies, we demonstrate how this approach simplifies the application of the toolbox in real-world scenarios, guiding early design decisions and ensuring that products are both safe and environmentally sustainable.

We will explain with detailed reference examples how our solutions are enabling innovative product development combined with safety assessment, shifting the work process from a reactive to a proactive practice that anticipates new regulatory standards and aligns with industrial and consumer expectations for safer, higher quality, and more sustainable products.

UK participants of proje cts are supported by UKRI. CH participants project receive funding from the Swiss State Secretariat for Education, Research and Innovation (SERI).

6.04.P-We497 Comprehensive Hazard Assessment of Novel Biobased Coatings Under the SSbD Framework - The TORNADO Project

Ioannis Liagkouridis, *Ziye Zheng, Asa Motiei, Gunnar Thorsen and Haakan Stripple, Swedish Environmental Research Institute (IVL), Sweden*

The human health and environmental risks of poly- and perfluorinated alkyl substances (PFAS) has led to bans and restrictions on their production and use and highlighted the need for safer and more sustainable alternatives to be used in coating applications. Aligning with the EU Green Deal and Chemicals Strategy for Sustainability strategies towards a circular economy and a toxic-free environment the TORNADO project aims to develop new organic and hybrid PFAS-free coatings that are safe and deliver environmental, societal, and/or economical value through their applications in packaging, textile, and kitchenware. To ensure that those coatings present indeed a safer and more sustainable alternative to PFAS-based ones, TORNADO is set to closely follow the criteria defined under the EU Safe and Sustainable by Design (SSbD) framework. A safety assessment of the TORNADO chemicals and materials is dictated under the SSbD framework which among others requires a comprehensive hazard assessment of the intrinsic properties of the chemical or material in order to understand their hazard potential before further assessing the safety during use. Using a combination of literature data, in silico QSAR (Quantitative Structure-Activity Relationship) and machine learning based tools and read-across methods the human health and environmental hazard profiles of TORNADO candidate coatings are generated. The hazard endpoints assessed include environmental fate properties (i.e., P, B or M criteria) as well as relevant toxicological endpoints such as mutagenicity, carcinogenicity, developmental and reproductive toxicity, endocrine disruption, skin sensitization and aquatic toxicity among others. As part of the assessment the degradation/transformation products of the main building blocks of the TORNADO coatings are predicted using in silico transformation pathway prediction tools and the hazard profiles of major abiotic and biotic degradation products are considered. An automated workflow is developed and applied in the form of a hazard screening tool that involves the following steps (1) screening over selected regulatory and other hazard information databases as well as the execution of in silico prediction models to collect both experimental and in silico hazard data, (2) generation of a chemical/material hazard profile as a straightforward heat map, and (3) identification of data gaps and/or data uncertainties.

Disclaimer/Disclosure: The TORNADO project has received funding from the European Union s Horizon Europe research and innovation programme under grant agreement No 101091944

6.04.P-We498 The PARC Safe and Sustainable by Design toolbox: An Integrative Toolbox for the Operationalization of SSbD

Dimosthenis Sarigiannis[1], ***Fotini Nikiforou[1]****, Achilleas Karakoltzidis[1], Anna Agalliadou[1], Jaco Westra[2], Bernd Nowack[3], Tomas Vilhelm Rydberg[4], Vrishali Subramanian[2], Joanke van Dijk[3], Maja Halling[4], Gianluca Selvestrel[5], Emilio Benfenati[5] and Spyros Karakitsios[1], (1)Aristotle University of Thessaloniki, Greece, (2)National Institute for Public Health and the Environment (RIVM), Netherlands, (3)Swiss Federal Laboratories for Materials Science and Technology, Switzerland, (4)Swedish Environmental Research Institute, Sweden, (5)Mario Negri Institute for Pharmacological Research, Italy*

In 2022, the European Commission (EC) introduced the Safe and Sustainable by Design (SSbD) framework, a voluntary premarket approach that promotes chemical innovation through the integration of safety and sustainability early in the design phase. The SSbD framework, as described by the EC Joint Research Centre (JRC), comprises two phases, the (re)design and assessment phases, respectively. One of the objectives of the European Partnership for the Assessment of Risks from Chemicals (PARC) is the development of the PARC SSbD toolbox for the operationalization of the EC SSbD framework. The PARC SSbD toolbox is designed to serve as a comprehensive and integrative toolbox for professionals, researchers and regulators that will provide all relevant methods, tools and data for SSbD. The alpha version of the PARC SSbD toolbox is nearing completion and is structured around an enhanced methodological framework, that integrates advanced methods for hazard, exposure, risk, and sustainability assessment. A comprehensive overview and review of available tools that can support SSbD was conducted. The tools were structured and mapped in accordance with the five stages of innovation (stage-gate model) and the five SSbD steps. The launch of version 0.1 the testing version of the SSbD toolbox introduced two new interfaces designed to enhance the assessment and decision-making process, accordingly: the SSbD wizard and the SSbD Scoring and Evaluation tool. These two elements are further refined during the development of the alpha version of the toolbox. Two tools have been successfully integrated VEGA and INTEGRA and additional tools will be incorporated into the platform. The PARC SSbD toolbox development follows a concurrent engineering and iterative approach. As it progresses towards its first official version, the development of a more informative decision support system that will facilitate the design and assessment of new and existing substances is structured.

6.05.A Implementing Holistic SSbD Approaches to Chemicals and Materials: What Do Academia, Industry, Regulators and Policymakers Propose?

6.05.A.T-01 Enhancing the Communication in the Value Chain for the Safe and Sustainable by Design Framework Implementation

Irantzu Garmendia Aguirre, *Hubert Rauscher and Kirsten Rasmussen, European Commission, Joint Research Centre (JRC), Italy*

"Key for the green industrial transition is the SSbD framework developed by the JRC to ensure the placement on the market of chemicals, materials and products that are safe and sustainable by design (SSbD).
The framework puts together safety, environmental sustainability and socio-economic dimensions for the first time. In addition, it requires consideration of the safety and sustainability throughout the entire life cycle of chemicals, materials and products, starting this assessment from the beginning of the R&D, shifting away from the current practice. Thus, the framework goes beyond current legislation and represents a paradigm shift in the way that innovation is done.
In a first step towards improving the relevance, reliability and operability of the SSbD framework in R&I activities, envisioned by the European Commission (EC) Recommendation, the JRC has published the first methodological guidance reflecting the experience gained since the publication of the Framework in relevant works like:
a) The application of the Framework to three case studies: i) Non phathalate plasticisers in Food Contact materials, ii) Enzymes in the scouring process of textiles and iii) Halogen free flame retardants in Information and communication technologies.
b) The 1st edition of the SSbD Bootcamp organized and hosted by the JRC.
c) The first feedback collection phase of the 2-year testing period proposed by the European Commission's (EC) Recommendation establishing a European assessment framework for safe and sustainable by design (SSbD) chemicals and materials [5].
Among the novelties introduced by the guidance, the scoping analysis highlights the importance of life cycle engagement in the SSbD Framework implementation that will be the focus of this presentation. The presentation enlarge on the broader meaning of the life cycle perspective and the importance of expert engagement (with a particular focus on the value chain experts) for the successful implementation of the Framework.

6.05.A.T-02 Stakeholder Engagement for Advancing Socio-economic Assessment in Safe and Sustainable by Design

Claudia Mair-Bauernfeind[1]*, Sarah Wunscher*[1]*, Martina Zimek*[1]*, Julia Voglhuber-Holler*[2]*, Carolin Tetyczka*[3] *and Clemens Wolf*[2]*, (1)Department of Environmental Systems Sciences, University of Graz, Austria, (2)BioNanoNet Forschungsgesellschaft mbH, Austria, (3)Research Center Pharmaceutical Engineering GmbH, Austria*

Over the past few years, it has become increasingly clear that concepts such as Safe and Sustainable by Design (SSbD) are an important part of the early stages of innovation and product development. However, there is still a lack of expertise on what needs to be considered in a thorough assessment as well as access to reliable databases for the implementation of SSbD. In particular, further developments of the SSbD approach within the fifth and final step of the framework, the socio-economic assessment are required. In early innovation stages, this is still challenging as final material compositions and actors in the value chain are often unknown. In addition, there is a lack of knowledge and strategies on how to fill this gap to propose a holistic and implementable SSbD approach. Hence, the focus of the present work is to investigate the possibilities to assess potential social impacts with a focus on two different value chains in the pharmaceutical industry (i.e., a COVID-19 vaccine available on the market and a nanoemulsion in early stages of development). Within this study, a multi-method approach is established to investigate 1) which methods are available to quantify social risks/impacts in the context of SSbD, 2) which stakeholders need to be considered and which topics should be included for the assessment of the pharmaceutical products and 3) which topics can be related to technology or product-related design parameters. Besides reviewing relevant literature and desktop research, the stakeholder consultation process is a three-step approach: (1) expert interviews to explore stakeholder groups and relevant social topics to be considered; (2) a standardized survey to prioritize topics among stakeholders and experts in the industry; and a focus group workshop with people developing pharmaceuticals to identify technology relevant social topics. The obtained results are a list of social topics which can be related to technology type and feature including methods and indicators for quantification that should be considered in step 5 of the SSbD when assessing product systems in the pharmaceutical industry. In conclusion, the present study underscores the need for streamlined tools for early-stage assessments and collaborative approaches to stakeholder engagement to fully integrate social considerations into SSbD practices in the pharmaceutical industry.

Disclaimer/Disclosure: The research for this work has received funding from the Federal Ministry of the Republic of Austria for Climate Action, Environment, Energy, Mobility, Innovation and Technology (BMK) through the Austrian Research Promotion Agency (FFG) (PHASE5 - NanoEHS 2023 national). The Research Center Pharmaceutical Engineering (RCPE) is funded within the framework of COMET - Competence Centers for Excellent Technologies by BMK, BMAW, Land Steiermark, and SFG. The COMET program is managed by the FFG.

6.05.A.T-03 Combining Policy and Industry Perspectives for building a Safe and Sustainable by Design Scoping Approach

Vrishali Subramanian[1], *Maja Halling*[2], *Susanne Resch*[3], *Fotini Nikiforou*[4], *Alicja Mikolajczyk*[5], *Achilleas Karakoltzidis*[4], *Anna Agalliadou*[4], *Dayna Schultz*[4], *Joanke van Dijk*[6], *Mirjam Schuijff*[1], *Therese Karnman*[2], *Eleni Iacovidou*[7], *Veruscka Leso*[8], *Emma Stromberg*[2], *Spyros Karakitsios*[4], *Araceli Sanchez Jimenez*[9], *Dimosthenis Sarigiannis*[4], *Ivo Iavicoli*[10], *Bernd Nowack*[6], *Jaco Westra*[1] *and Tomas Vilhelm Rydberg*[2], *(1)RIVM, Netherlands, (2)Swedish Environmental Research Institute (IVL), Sweden, (3)BNN, Austria, (4)AUTH, Greece, (5)QSAR Lab, Poland, (6)EMPA - Swiss Federal Laboratories for Materials Science and Technology, Switzerland, (7)Brunel University, United Kingdom, (8)University of Naples Federico II, Italy, (9)INSST, Spain, (10)UNINA, Italy*

Safe and Sustainable by Design (SSbD) has a broad vision and requires technical expertise in safety and sustainability assessment & design. Policy& industry are grappling with a practical operationalization of SSbD. EC s SSbD framework is currently being systematically refined with stakeholder feedback & case study application. Safety & sustainability considerations in chemical companies are included as part of Portfolio Sustainability Assessment, and often included in stage gates. SSbD operationalisation requires development of content and process aspects of a scoping approach. Scoping involves contextualization of SSbD in early innovation, prioritizing parameters, linking assessment to (re)design & providing a decision logic to support SSbD results interpretation. PARC 8.1 conducted two activities: a) comprehensive tool testing case study on Bisphenol A, b) group interviews of companies on how they currently conduct safety and sustainability assessment during innovation. A scoping approach is being developed by combining the top down perspective of policy and industry, with the bottom up perspective from tool application. We describe how a scoping approach is being developed in PARC 8.1: a) How does industry currently apply safety and sustainability in their innovation process?b) What are the similarities and differences between the EC and CEFIC approaches? c) What aspects of the EC and CEFIC guidance does the BPA case study currently cover? d) What are recommendations for further development of the scoping approach? The key findings of this investigation for developing a scoping approach include: a) While innovation within chemical companies is diverse, depending on the sector and starting point, we that the SSbD system is operationalized through a multidisciplinary team including SSbD topic experts along with a innovation manager. b) The early stages of innovation are particularly influenced by expert judgement and other qualitative approaches, c) The comparison of the EU and CEFIC guidance showed that the two frameworks address different levels of SSbD, and thus differ in their focus on SSbD assessment/redesign content and process. Some assessed criterial include differences include focus on innovation, SSbD assessment level, assessment unit of analysis, assessment approach, (re)design approach, and trade-off approach. Recommendations for the development of a practical scoping approach to support operationalization of SSbD will be discussed.

6.05.A.T-04 Value Creation and Tiering: Incentives of SSbD Integration Into Industrial Innovation Projects With LCA and Measured Safety Screenings

Wendel Wohlleben, *BASF SE, Germany*

The sustainability transformation is not reached by endorsement alone, but by a myriad of innovations. Qualitative considerations of SSbD principles are common in industry, but quantitative approaches to early screenings of the different SSbD dimensions including hazard, occupational safety, environmental and consumer safety, environmental sustainability, cost, performance, and environmental benefits are rare. In the present contribution, we focus on incentives, and develop scenarios in which SSbD creates an added value also in the well-established economic measures of an R&D pipeline. We employ the established measure of the Expected Commercial Value (ECV), which is a common basis for the investment decision at every gate. It depends on a business case with projected costs for the technological development, and costs for market launch. In our SSbD scenarios, we assume that the consideration of tradeoffs (not favoring simply the best performing material, but the one with the best balance of all SSbD dimensions) has an impact on the probability of technological success. We also postulate that under the big societal trend towards the sustainability transformation, the value chain will increasingly see a value in more formalized, more standardized, more quantitative SSbD approaches, thus impacting the probability of commercial success. In one scenario for a project aiming to develop a high-value innovative product, one can demonstrate that the application of full SSbD at early R&D stages removes the economic incentive to fund such a project (Figure 2). It becomes evident that it is essential which intensity of SSbD work at which time is planned, because there is a high probability that the project will never come to that stage because of the overall evaluation of all SSbD dimensions, including technical feasibility, cost and performance, at each gate. However, tiering with a selection of NAMs nearly turns the tide, and the profitability is restored if the value chain sees a value in the implementation of more formalized SSbD practices. In summary, if the SSbD efforts are adapted to the scenario, are systematically tiered, starting from scoping and simplified comparative assessment, and if the market adoption depends on a justified balance of all SSbD dimensions, then there is an economic incentive, and SSbD pays off.

6.05.P-Tu446 A Multi-actor Approach to Facilitate the SSbD Implementation in SURFs UP Bio-based Value Chains

Socorro Vazquez-Campos[1]*, Virginia Cazzagon*[1]*, Ruben Martínez*[1]*, Ana Candalija*[1]*, Camilla Delpivo*[1] *and Sofie Lodens*[2]*, (1)Leitat Technological Center, Spain, (2)Bio Base Europe Pilot Plant vzw, Belgium*
Currently only 4% of the surfactant market share consists of compounds that are 100% based on biomass (fully biobased surfactants), while there is an urgent need for non-hazardous Safe and Sustainable by Design (SSbD) biosurfactants (BSs). The biosurfactant market is expected to grow at a CAGR (Compound Annual Growth Rate) of between 5.2 and 10.5% between 2022 and 2028. However, the diversity of the currently available safe and sustainable biosurfactants is not at all sufficient to meet the market needs: diversity is key. SURFs UP proposes a (integrated) combination of biological & green chemical production routes from (waste) biomass second generation (2G) feedstocks and following SSbD criteria which will allow a dramatic transformation of the surfactant market by offering the broad diversity of safe and sustainable alternatives at a reasonable cost that the market is looking for. SURFs UP will bridge this gap by demonstrating optimized and cost-efficient processes for 9 SSbD biosurfactant products that will be formulated in prototypes in home- and personal care and agrochemical applications. These ingredients will be fully characterized and evaluated according to the EC SSbD Framework criteria. Finally, the production of SSbD BSs will be scaled up and used to demonstrate prototype formulations in home care, personal care, and biopesticide applications. SURFs UP project activities implement a multi-actor approach according to the quadruple helix innovation model, where science, policy, industry, and society are involved in the technology development and innovation process. This ensures that all the relevant actors and end-users in the bio-based value chain are appropriately involved. In SURFs UP a decision-making process will be implemented (e.g., stage to gate) along the supply chain to promote the integration of the SSbD principles in all stages of product development, use and end-of-life. We ensure an active and iterative flow of information from the start of the project, with all the actors involved in the products development, through meetings and workshops. Important information will be produced throughout the project which will be analyzed in an integrated way.

Disclaimer/Disclosure: The project is supported by the circular bio-based Europe Joint undertaking and its member. Funded by the European Union. Views and opinions expressed are however those of the author(s) only and do not necessarily reflect those of the European Union or CBE JU. Neither the European Union nor the CBE JU can be held responsible for them.

6.05.P-Tu455 How Can Innovation Management Support SSbD?

Nina Melander*, Research Institutes of Sweden, Sweden*
The Safe and Sustainable by Design (SSbD) framework is a transformative approach to innovation, embedding safety and sustainability into the design of chemicals and materials. Addressing the "triple crisis" of climate change, biodiversity loss, and pollution, it aligns innovation with societal, safety and environmental goals. However, operationalizing SSbD principles demands rethinking traditional

innovation processes to integrate safety and sustainability alongside economic and functional performance, introducing new complexities and uncertainties.

Key challenges include managing trade-offs across safety, environmental, social, and economic dimensions, evaluating long-term impacts, and addressing stakeholder concerns from the design phase onward. While managing uncertainty is inherent in innovation, SSbD introduces novel uncertainties related to sustainability metrics, regulatory requirements requiring systematic and adaptive solutions.

Structured innovation management systems (IMS), such as those outlined in the ISO 56000 can guide alignment with organizational objectives through leadership commitment, strategic direction, operational planning, and continuous improvement. By integrating SSbD principles into an IMS, organizations could potentially foster a culture of innovation that prioritizes safety and sustainability.

The ISO 56000 series outlines eight principles that could support SSbD, for example realizing value, future-focused leadership, adaptability, and managing uncertainty. However, IMS frameworks can be complex, particularly for SMEs. To address this, the study will focus on a simplified model, 4F (Capability for Renewal). 4F focuses on monitoring external trends, managing internal resources, goals with purpose, and the innovation process.
By exploring synergies between ISO 56000 and SSbD, this work offers a first view into practical strategies for embedding safety and sustainability into innovation processes.

6.05.P-Tu462 Bringing Safe-and-Sustainable-by-Design to the Public – Exploring Stakeholders' Concerns and Needs Towards Nanotechnologies

*Jan Hildebrand[1], **Stefanie Prenner**[2], Caitlin Ahern[3] and Beatriz Alfaro Serrano[3], (1)IZES gGmbH, Germany, (2)Brimatech Services GmbH, Austria, (3)BioNanoNet Forschungsgesellschaft mbH, Austria*

Nanomaterials are characterised by their great potential in research and industry, but at the same time are still relatively little known to the public. Even though many application areas of nanomaterials, including cosmetics, medicine and electronics, are advancing to provide a more Safe-and-Sustainable-by-Design (SSbD) approach, public perceptions towards nanotechnology are sceptical. Within this study, a multi-method approach was used in order to examine relevant factors on public and stakeholders perceptions. Firstly, a multi-level media analysis in Germany observed the societal discourse on nanomaterials, different actor groups and factors of public acceptance. This analysis included data from newspaper articles (N=272), semi-scientific magazine articles (N=99) and on the social media level user comments from thirteen YouTube videos on nanotechnology advancements. Following, expert interviews and a pedestrian survey in Germany (N=34) were conducted to prepare an expert workshop (N=20) to discuss the potential and challenges of public trust towards nanomaterials in sunscreens. In addition, a survey along stakeholders in nanotechnologies was conducted.

Findings from the media analysis showed that the reporting of technology development was predominantly descriptive and did not discuss the social implications for the public. There was an ambiguity concerning the health and ecological risks of nanomaterials in the articles, which portrays the scientific uncertainty of this technology. Furthermore, social media users were opinionated towards nanotechnology, ranging from sceptical views of potential misuse to hopeful and curious outlooks on the future of applications. There tends to be disappointment in not receiving the promised advancements in nanoscience, shaped by its intangible nature and existing associations of the technology. Thus, there is a need for continued efforts to enhance public engagement by increasing and diversifying the range of topics in news reports and creating outreach activities from social media channels to disseminate information. Based on the results and under the motto Bringing SSbD to the public , information and communication materials such as factsheets and a nano-quiz were developed and distributed, thereby gaining important experience in how people can be reached and addressed on this complex topic through science communication.

Disclaimer/Disclosure: The research leading to these results has received funding from the European Union s Horizon 2020 research and innovation programme under grant agreement No 953152.

6.05.B Implementing Holistic SSbD Approaches to Chemicals and Materials: What Do Academia, Industry, Regulators and Policymakers Propose?

6.05.B.T-01 Redefining Drug Innovation: How to Integrate the Safe and Sustainable by Design (SSbD) framework to the Pharmaceuticals and Nanomedicines Sector
Jacopo Sorani[1]*, Roland Hischier*[2] *and Bernd Nowack*[2]*, (1)EMPA / Eth Zurich, Switzerland, (2)EMPA - Swiss Federal Laboratories for Materials Science and Technology, Switzerland*
The pharmaceutical industry plays a vital role in global health but faces growing scrutiny over environmental risks posed by active pharmaceutical ingredients (APIs) and their metabolites. These compounds, often entering the environment through excretion or manufacturing, persist and impact ecosystems. Examples include the feminization of fish caused by 17?-ethinylestradiol. The detection of over 156 APIs in European waters, with concentrations up to 10 µg/L, highlights the need for sustainable solutions.

The Safe and Sustainable by Design (SSbD) framework, part of the Chemical Strategy for Sustainability, aims to integrate safety and sustainability into material design from the earliest stages. However, adapting SSbD to pharmaceuticals requires addressing challenges such as strict regulatory requirements, long R&D timelines, and emerging technologies like nanomedicines.

This study examines how SSbD principles can fit into the drug development process. Key phase such as Drug Discovery, Lead Optimization, Pre-clinical Studies, and Clinical Trials, were analyzed to identify integration points without disrupting functionality. Existing data on toxicology and pharmacokinetics were found to support SSbD, reducing additional testing and costs. Three scenarios were evaluated: Simplified SSbD, starting early but increasing complexity; Intermediate SSbD, introduced during Lead Optimization for balance and re-design opportunities; and Complete SSbD, applied late with limited flexibility. The Intermediate scenario was deemed the most practical, leveraging existing data while minimizing costs.

Cost analyses showed modest increases: $1.9 million (0.033% of the phase budget) for hazard assessments during Lead Optimization and $10,000 $30,000 per compound (0.22%) for Life Cycle Assessments in Pre-clinical Studies. To enhance sustainability evaluations, the EA-DALY (Environmental Assessment Disability-Adjusted Life Year) metric was proposed, balancing health benefits with environmental impacts. The handprinting approach complements this by highlighting positive lifecycle contributions, such as reduced environmental burdens.
Nanomedicines introduce unique challenges due to nanoparticle complexity, requiring tailored hazard assessments and alignment with advanced materials guidelines. By adapting SSbD, the pharmaceutical sector can address these challenges while supporting innovation and sustainability.

Disclaimer/Disclosure: This MSCA PhD is funded under the grant agreement 101073025 (MELOMANES PROJECT) and has received funding from the Swiss State Secretariat for Education, Research and Innovation (SERI). 6.05.B.T-02 Enabling Safe and Sustainable Innovation: Transparent Decision Support
Hedwig Braakhuis[1]*, Neeraj Shandilya*[2]*, Susan Dekkers*[2]*, Thomas Hennequin*[2]*, Felipe Blanco Rocha*[2]*, Wouter Tabingh Suermondt*[2]*, Mark Huijbregts*[3] *and Wouter Fransman*[2]*, (1)National Institute for Public Health and the Environment (RIVM), Netherlands, (2)TNO, Netherlands, (3)Radboud University Nijmegen, Netherlands*
Safe and Sustainable by Design (SSbD) provides an opportunity to proactively design innovative products that not only provide solutions to societal challenges, such as the energy transition, but also ensure no harm is caused to humans or the environment. Achieving this delicate balance between performance, health, safety, sustainability, and costs necessitates an integrated approach during all phases of product innovation.

We present a transparent and tiered decision support approach for companies to implement SSbD for their products or portfolio, and for regulators to transparently visualize the impact of substitution. The engagement of relevant stakeholders is key in the approach. In the first step, design criteria for performance, health, safety, sustainability and costs are selected based on stakeholder input, including company management, investors, regulators and local residents. The second step is a screening-level assessment of the potential human health, environmental and social hotspots in the life cycle of the chemicals, materials, and products under consideration. The third step is a transparent visualization of the performance, health, safety, and sustainability profile of the selected design, complete with uncertainty indicators. The decision support approach identifies specific aspects that demand additional attention or

action. The fourth step is to bring the relevant people together to discuss trade-offs between SSbD aspects and make a decision on the next step of the product/chemical design. In case information is lacking to allow decision making, the fifth step is to gather additional information by for example conducting measurements, which will feed again into the visualization to aid decision making. These steps are iteratively repeated at successive development stages of the product innovation.

To demonstrate the transparent SSbD decision support, several case studies have been conducted. The output shows that the SSbD decision support empowers industries to test scenarios and effectively balance risks and benefits along their design process, taking stakeholder needs into account. Moreover, the approach supports regulators to transparently visualize the impact of substitution of substances of concern thus avoiding regrettable substitution and contributing to the creation of a healthier and more sustainable society.

6.05.B.T-03 Benchmarking the "Safety and Sustainability by Design" (SSbD) Culture
Claire Mays[1]*, Sean Hardy*[1]*, Fanny Karatchodjoukova*[1] *and Raquel Bohn-Bertoldo*[2]*, (1)Institut Symlog de France, France, (2)Aix-Marseille University, France*
In the domain of nanotechnologies, safety and sustainability can be anticipated and actuated from the earliest stages of development of new particles and advanced materials, nano-enabled products, and Research & Innovation activities. Throughout the early 2020s, a strong and accelerating movement is observed in academia, government, and industry towards definition, operationalization, and application of such Safe and Sustainable by Design (SSbD) concepts and strategies.

This mindful movement has a sociocultural dimension, elaborating its own practices, vocabulary, relationships among stakeholders, beliefs, values, and more. Study of SSbD s emerging sociocultural profile in this seminal period of rapid development can capture areas of controversy and ideas in transition, and furnish an interesting benchmark. In 2023, the Responsible Research and Innovation (RRI) team of the Horizon 2020 SAbyNA project therefore performed a large anonymous survey (N=172) of how the nanotech and advanced materials communities conceive of SSbD. A pilot study (n=161) from 2021 enabled comparisons and trend analysis.

Empirical social psychology methods and concepts were employed to benchmark so-called "social representations" of SSbD. Expert stakeholders were invited to share their implicit definitions, agreement or disagreement on selected facets of achieving nanosafety and sustainability. Analysis shows increasing complexity of SSbD concepts within the community. Preventive safety strategies emerge as a frame for considering materials and processes, and as a driving force to achieve One Health -type outcomes. Environmental aspects of sustainability are foremost in mind, but a strong desire to develop socio-economic aspects is clear. An SSbD community culture emerges, characterized by the powerful and consensual conviction that SSbD will improve environmental health and occupational safety. Participants recognize that SSbD induces a new mentality and are highly engaged. Areas of dissensus were identified as well. While respondents agree that SSbD will not hinder innovation, views on operational challenges, including cost, are more scattered. We identify these less settled attitudes as warranting further discussion and debate.

Such survey results, and moreover repeat measures in coming years, can support interdisciplinary, cross-sector stakeholder dialogue, consolidate the community, and facilitate access to improved SSbD guidance.

Disclaimer/Disclosure: Work funded under the EU Horizon 2020 research and innovation programme grant agreement n° 862419, in SAbyNA: Simple, robust and cost-effective approaches to guide industry in the development of safer nanomaterials and nano-enabled products ,

6.05.B.T-04 An Auto-diagnostic SSbD Tool to Facilitate the Integration of Safe and Sustainable by Design Approach in the Innovative Stage
Josephine STECK *and Cecile Philippot, Univ. Grenoble Alpes, CEA, France*
Since the publication of the draft Safe and Sustainable by Design (SSbD) framework by the Joint Research Center, the European Commission has initiated several actions to support the evaluation and future deployment of this approach. However, the SSbD assessment remains a complex and resource-intensive

process. This study proposes an initial, simplified SSbD assessment to minimize data requirements, reduce time investment, and lower the level of specialized expertise necessary, aiming to make SSbD more accessible and efficient while preserving its core objectives.
A three-tiered approach is introduced, with Tier 1 focusing on a simplified evaluation applicable to all considered alternatives. This tier is designed to facilitate early-stage integration of the SSbD approach. A generic questionnaire was developed to enable easy comparison between the reference and alternatives across four SSbD dimensions: safety, environment, economic, and social. The Tier 1 assessment serves as an auto-diagnostic tool, evaluating each SSbD dimension through a set of up to 10 generic questions. The user selects a score (0 for "No" or "I don't know", 5 for "Partly", and 10 for "Yes") for each question, and results are aggregated to provide a percentage score for each dimension, which is then weighted to yield an overall score. This evaluation highlights gaps and provides a foundation for developing an improvement plan and guiding higher-tier SSbD assessments.
The Tier 1 assessment has been applied to molecules and final products (flame retardants, plasticizers, surfactants) as well as processes (hydrogen production), demonstrating its versatility as a "quick-and-easy" pre-assessment tool.
The primary advantage of this Tier 1 auto-diagnostic tool is its ability to enhance the agility and adaptability of research and innovation (R&I) strategies. While it offers a first-level identification of the SSbD status of an alternative with minimal data, it also enables the identification of key gaps and outlines necessary next steps. In the comprehensive, multi-tiered SSbD approach, the generic questions from Tier 1 will be refined and consolidated in higher tiers, where more detailed, expert-driven assessments (Tier 2 and Tier 3) will involve a deeper focus on each SSbD dimension, including the participation of R&I experts.

6.05.P-Tu442 Screening Sustainability Assessment of Innovative Bio-Based Solution for Art Restoration

***Martina Menegaldo**[1], Elisa Giubilato[2], Lisa Pizzol[2], Elena Badetti[1] and Elena Semenzin[1], (1)Ca Foscari University of Venice, Department of Environmental Sciences, Informatics and Statistics, Italy, (2)GreenDecision S.r.l., Italy*

Within the HEU GREENART project, an assessment approach was developed to evaluate the safety and sustainability of innovative solutions for art restoration, including protective coatings, foams and packaging materials, consolidants, gels and cleaning fluids, and green tech sensors. This approach, developed taking in consideration the Safe and Sustainable by Design (SSbD) Framework and the Nanorestart Framework, is structured into three iterative stages. Stage 1 involves the Hazard Assessment of innovative ingredients and formulations. Stage 2 includes a Screening Sustainability Assessment. Stage 3 focuses on assessing the sustainability performance of the most promising solutions identified in the earlier stages, through Life Cycle Assessment (LCA). This study focuses on the stage 2 of the GREENART approach: the Screening Sustainability Assessment, developed during the second year of the project and already used to guide the decision-making process. This assessment is conducted through a questionnaire structured around three main aspects: Functionality, Safety and Sustainability. The three aspects are assessed across the entire life cycle of GREENART's innovative products and benchmarks. Each aspect is assessed through specific criteria, providing measurable indicators of sustainability performance. The criteria help in determining the significance and impact of each aspect within the life cycle stages. Finally, the assessment incorporates targeted questions designed to evaluate compliance with the established criteria. Each question has five possible answers, representing the level of satisfaction with a specific product solution, ranging from "excellent" to "bad". These scores are then averaged to visualize the overall results across the different life cycle stages and sustainability aspects.
The safety aspect is assessed by combining the Hazard Classification from Stage 1 of the GREENART approach with an Exposure Classification, inspired by the ProScale method, within the GREENART Control Banding Matrix.
The results of the Screening Sustainability Assessment will be presented for one case study, selected from GREENART s innovative products and related benchmarks.
This approach aligns with the SSbD framework, ensuring compliance with evolving European and

international chemical safety regulations while continuously improving the safety and sustainability profile of these products.

6.05.P-Tu447 The SUNRISE SSbD Integrated Impact Assessment Framework

*Lisa Pizzol[1], **Arianna Livieri**[1], Alex Zabeo[1], Sarah Devecchi[1], Alberto Katsumiti[2], Andrea Brunelli[3], Elisa Giubilato[3], Michael Saidani[4], Konstantina Koutsiara[5], Carlos Fito[6], Jamea Baker[7], Blanca Suarez Merino[7], Stella Ivanova Stoycheva[8], Yasemin Ertugrul[8], Hubert Rauscher[9], Irantzu Garmendia Aguirre[9] and Danail Hristozov[10], (1)GreenDecision S.r.l., Italy, (2)GAIKER Technology Centre, Basque Research and Technology Alliance (BRTA), Zamudio, Spain, (3) Ca' Foscari University of Venice, Italy, (4)LIST Luxembourg Institute of Science and Technology, Luxembourg, (5)HYPERTECH SA, Greece, (6)ITENE Parque Tecnologico, Spain, (7)TEMAS Solutions GmbH, Switzerland, (8)Yordas Group, Germany, (9)European Commission, Joint Research Centre (JRC), Italy, (10)Emerge Ltd, Sofia, Bulgaria*

As part of the European Green Deal, the Chemicals Strategy for Sustainability and the Zero Pollution Action Plan highlight the critical need for a Safe and Sustainable by Design (SSbD) approach to chemicals and materials. To drive this transformation, the European Commission (EC) has recommended the establishment of a European assessment framework for SSbD of chemicals and materials, based on a holistic approach developed by the EC's Joint Research Centre. To facilitate the practical adoption of the EC-JRC framework by stakeholders, particularly within the industry, the Horizon Europe SUNRISE project has been funded to develop integrated methodologies for assessing the health, environmental, social, and economic impacts of products enabled by advanced materials (AdMa). The SUNRISE project combines the bottom-up development of methods and tools for assessment of health, environmental, social and economic impacts with their top-down integration in an overarching Integrated Impact Assessment Framework (IIAF). This framework is designed to support SSbD decision-making along supply chains and lifecycle stages of AdMa and their products. The process of developing and testing the IIAF in cocreation with the stakeholders within a trusted real-world environment will improve our understanding of stakeholders needs, perceptions and relevant SSbD aspects to be considered, along with potential safety and sustainability trade-offs. This new knowledge will be transferred to regulators and policy makers at EU and national level to support them in the implementation of SSbD-related policies for chemicals and materials. The IIAF is composed of 4 assessment Tiers, fully aligned to the 5 steps of the EC-JRC SSbD framework, where each tier corresponding to an integrated methodology (supported by a toolbox) for health, environmental, social and economic impact assessment targeting different groups of users at different stages of the innovation process and requiring a different level of data and expertise. The implementation of the IIAF will ensure better regulatory compliance for AdMa based products and can have an impact on shortening the time of new materials/products to reach the market, thereby supporting the Green Deal policy objectives for the transformation of the EU into a modern, resource-efficient and competitive economy.

Disclaimer/Disclosure: This work has been carried under the SUNRISE project grant agreement No 101137324

6.05.P-Tu458 Methods and Tools to Assess Exposure and Risk for Steps 2-3 of the SSbD Framework for Advanced Materials

***Vicenc Pomar-Portillo**[1], Alberto Katsumiti[2], Isabel Rodriguez-Llopis[3], Blanca Suarez Merino[4], Andrea Brunelli[5], Elena Badetti[5], Elisa Giubilato[5], Erik Laurini[6], Carlos Fito[7], Santiago Aparicio[8], Janeck J Scott-Fordsmand[9], Morgan Lofty[10], Danail Hristozov[11] and Bernd Nowack[1], (1)EMPA - Swiss Federal Laboratories for Materials Science and Technology, Switzerland, (2)GAIKER Technology Centre, Basque Research and Technology Alliance (BRTA), Spain, (3)GAIKER, Spain, (4)TEMASOL, Switzerland, (5)Ca Foscari University of Venice, Italy, (6)Universita degli studi di Trieste, Italy, (7)ITENE, Spain, (8)Universidad de Burgos, Spain, (9)Aarhus University, Denmark, (10)Institute of Occupational Medicine (IOM), United Kingdom, (11)Green Decisions, Italy*

The European Commission's Safe and Sustainable by Design (SSbD) framework represents a pivotal initiative to integrate safety, environmental sustainability, and societal benefits into the design of materials and chemicals. Advanced Materials (AdMa), including nanomaterials and multicomponent systems, present unique challenges to this framework due to their dynamic properties, life-cycle transformations, and diverse application scenarios. Steps 2 and 3 of the SSbD framework target the critical phases of production, processing, use, and disposal, requiring robust and adaptable tools to assess exposure and risks across these stages.

This study systematically reviewed 31 tools for exposure and risk assessment, categorizing them into three tiers based on complexity, data requirements, and usability. The review identified gaps in tool availability, with some tools outdated or inaccessible, and highlighted promising advancements from recent projects, although some are not yet widely available to the public. Additionally, challenges persist in addressing AdMa-specific behaviours, including aggregation, dissolution, and transformations throughout their life-cycle.

The findings underscore three critical challenges: persistent data gaps, the need for better integration of tools across life-cycle stages, and the limited accessibility of high-complexity tools for smaller enterprises. Overcoming these obstacles will require the development of adaptable methodologies, enhanced data-sharing practices, and cross-sector collaboration to make tools more user-friendly and broadly applicable. This study provides a comprehensive assessment of tool readiness and highlights actionable insights to support the effective implementation of SSbD principles for AdMa, paving the way for safer and more sustainable innovation.

Disclaimer/Disclosure: Acknowledgement - This work was supported by the European Union s HORIZON EUROPE research and innovation programme under Grant Agreement No. 101137324 (SUNRISE). CH participants in SUNRISE Project receive funding from the Swiss State Secretariat for Education, Research, and Innovation (SERI).

6.05.C Implementing Holistic SSbD Approaches to Chemicals and Materials: What Do Academia, Industry, Regulators and Policymakers Propose?

6.05.C.T-01 A Pragmatic Approach to Merge Concepts of Risk Assessment and Life Cycle Assessment Toward Operationalization of SSbD: A Case Study

Veronica Di Battista[1]*, Bart Kerre*[2]*, Kranti Navare*[2]*, Laura Lef vre*[2]*, Chrystelle Verhoest*[2] *and Nele Deleebeeck*[2]*, (1)Arcadis, Germany, (2)Arcadis, Belgium*

Despite some guidance from JRC on SSbD being available, a final framework has not been published yet. Therefore, experience from a case study could contribute to standardisation. We propose a pragmatic methodology to find a middle ground between SSbD dimensions (safety, sustainability and performance) by integrating concepts of risk assessment, life cycle assessment and lessons learned from working with companies across different sectors. Our approach is guided by the draft JRC framework and methodological guidance, the CEFIC SSbD guidelines and the roadmaps developed by multiple stakeholder consortia under EU s framework for R&D&I. We reviewed the information available in the current SSbD frameworks, guidelines and roadmaps and compared this with in-house experience to identify indicators, criteria and tools deemed applicable at each phase of the innovation process, by increasing the Technology Readiness level (TRL) of the portfolio solution.

The SSbD methodology was applied on different paint formulations containing organic and inorganic photostabilizers meant to prevent photodegradation of wood. The aim is to select the paint with the best compromise in terms of safety, sustainability and performance for wood protection by comparing with market standards, and explaining in a transparent way how a final decision on the best paint option was derived, avoiding absolute scoring. Different scenarios are analysed by considering the following variables: the complexity of the paint in terms of composition, data availability in common databases, company in-house tools and expertise, budget constraints tied to the stage of innovation and the likelihood of the product reaching the market.

Our case study highlights the importance of SSbD criteria harmonization, SSbD tools flexibility depending on the case study in analysis, the innovation stage and company-specific in-house availability. Transparency is key in the evaluation to fully operationalize SSbD. We identified the following challenges: criteria harmonization across sectors, lack of standardised weighting approaches, difficulty to get high quality data for LCA allowing differentiation of SSbD versions at early stages, lack of automation tools available to companies in house and hard communication across the supply chain.

6.05.C.T-02 Safe-and-Sustainable-by-Design Advanced Materials: Application of the HARMLESS Approach to Imogolites for Agricultural Application

Veronique Adam DR[1]*, Fabienne Testard*[2]*, Dorra Gargouri*[2]*, Arianna Filoramo*[2]*, Susan Dekkers*[3]*, Veronica Di Battista*[4]*, Eugene van Someren*[3]*, Wendel Wohlleben*[4] *and Blanca Suarez Merino*[1]*, (1)TEMAS Solutions GmbH, Switzerland, (2)CEA, France, (3)TNO, Netherlands, (4)BASF, Germany*

In this practical case study, functionalised imogolites developed for agricultural purposes (imo-OH, imo-CH3, Cu-imo-CH3) are taken through a flexible stage-gate innovation process and used to test the

HARMLESS SSbD Decision Support System (DSS) at early innovation stages.
All lifecycle stages and two flexible innovation stages were considered in the development of the DSS. First, at ideation and business case, the AMEA tool enables the categorisation of the material under study and the verification that the DSS is applicable. Then, still at these earliest stages of development, another tool was developed to raise Warning flags, produce design Advice and identify Screening Priorities (WASP). It consists of 12 questions addressing safety and environmental sustainability. Subsequently, at lab phase, the Alternative SSbD Inspector (ASDI) helps producing a matrix, which enables the integration of data on several material alternatives, including newly developed, conventional and benchmark materials. Based on descriptors triggered by WASP, various SSbD dimensions (i.e. performance, human safety, environmental safety, environmental sustainability) are assessed quantitatively and qualitatively to enable the selection of the best material alternative to proceed to pilot phase. The quantitative safety assessment is based on New Approach Methodologies, where available. The qualitative sustainability assessment is based on Sustainable Development Goals targets defined by the United Nations, whose descriptors have been tailored to the SSbD materials scope. The scoring system takes inspiration of the Portfolio Sustainability Assessment published by the World Business Council for Sustainable Development (WBCSD).
Results show that the Cu-imo-CH3 version raises most concern, as Cu is a toxic component and a critical raw material, and this imogolite version raises more flags regarding exposure through inhalation. Imo-OH and imo-CH3 are further differentiated using ASDI, with imo-CH3 showing the highest potential to be taken to pilot phase. Comparing these newly developed materials to conventional materials (i.e. Cu salts), ASDI also shows the benefits of developing functionalised imogolites on SDG 2, 12 and 14. By weighting information across several aspects of SSbD, the HARMLESS DSS results enable decision making by the material developer, influencing their design at early innovation stages.

6.05.C.T-03 Build on The International Fragrance Association (IFRA) Case-Study on methyl salicylate to Enhance the European Union Safe and Sustainable by Design (SSbD) Framework in 2025

***Annika Batel**, BASF, Germany*

In 2022, IFRA decided to proactively test the EU SSbD framework, during the 2-year testing period (by end 24).
Goals were: Identify challenges, trade-offs & gaps in the SSbD framework, focusing on safety-sustainability integration, data availability, and shared methodological understanding within industry & supply chains; Highlight necessary improvements before 2025 s framework revision; Assess the framework's applicability to complex substances and value chains, address gaps, and consider simplifications to support holistic approach.
A case study was conducted on methylsalicylate, a common fragrance ingredient sourced both naturally and synthetically and used in different applications. The two sources of production (natural & synthetic) and two end products (a cosmetic & a detergent) were analyzed and compared. The study evaluated the applicability of the draft SSbD framework across its first four steps. Social and economic sustainability aspects were outside the study's scope.
Step 1: Using ECHA database information, methyl salicylate was identified as a substance of concern. The hazard assessment was straightforward due to its REACH registration and harmonized classification, but such assessments could be more complex for unregistered or lower-tonnage substances. Step 2: Both synthetic and natural methyl salicylate manufacturers were contacted to evaluate worker exposure risks related to chemical handling and intermediate substances. In both production processes, potential risks could be identified where mitigation could improve safety. Step 3: Safety for human and environmental health was assessed based on end use in consumer products. Both uses were identified as safe for human health and the environment. Step 4: A life cycle assessment was completed for both sources and both applications, highlighting the differences of potential impact categories depending on the sourcing of the substance.
General key findings include significant data challenges (e.g., gaps, low-quality, confidentiality), limited supply chain expertise for safety and sustainability, and methodological challenges. There was also uncertainty in selecting appropriate sustainability assessment references, increased workload complexity due to typical fragrance compositions, and a need for clearer guidance within the SSbD framework.
Provide recommendations to improve the EU SSbD framework in 2025, aiming to make it a practical reference for safe and sustainable innovation.

6.05.C.T-04 Application of the Safe and Sustainable by Design (SSbD) Principle in the Development of Circular and Recyclable Composites for Automotive and Aerospace Sectors

***Elvira Villaro**[1], Julio Gomez[1], Andrea Porcari[2], Elena Destro[2], Olmo Guagnetti[2], Mireilla Miró[3], Daniel*

Peral Crespo[3], Ainhoa Tolentino[3], Isabel Rodriguez-Llopis[4], Alberto Katsumiti[4], Leire Barruetabeña[5], Amaia Garcia[5], Cyrille Durand[6], Christoph Olscher[7], Florian Part[7], Blanca Araujo[8] and Ana Branco[8], (1)Avanzare Innovacion Tecnologica, Spain, (2)Italian Association for Industrial Research (AIRI), Italy, (3)ONYRIQ, Spain, (4)GAIKER Technology Centre, Basque Research and Technology Alliance (BRTA), Spain, (5)GAIKER, Spain, (6)TEMAS Solution GmbH, Switzerland, (7)University of Natural Resources and Life Sciences (BOKU), Austria, (8)SATURNTECH UNIPESOAL LD, Portugal

Innovation in materials and processes is leading to high performance multicomponent and multifunctional advanced materials. The integration of the Safe and Sustainable by Design (SSbD) framework in the early stages of this innovation process will speed their development, ensuring that risks and environmental impacts are not a drawback.

graphene-based materials (GBMs),and particularly graphene and graphene oxide (GO) have gained interest to enhance multi-functionality of structures and components used in high demanding applications, as in the aerospace and automotive industries, and often enable combination of materials with digital technologies. Examples of the benefits linked to the application of advanced additives in these sectors include: the reduction of the vehicle weight (e.g. embedding circuits to replace wires); the improvement of the efficiency of the production process (e.g. substituting critical raw materials and halogenated additives, and reducing energy demand in processing composites by enabling the use of infrared curing); the optimization of the use conditions (e.g., integrated structural health monitoring sensors into structural matrix and enhancing the flame retardancy of the matrixes).

The use of additives does not only have a significant impact on the material functionalities and performances,, but also on its safety and sustainability along the whole life cycle.

In this context, establishing and implementing a SSbD strategy is key to understand, at early stages of the material development, the balance between the benefits foreseen and potential risks that the adoption of GBMs additives could bring.

The REPOXYBLE EU funded project (2023-2026, GA 101091891) utilizes GBMs to enhance the thermal and electrical conductivity of epoxy-based polymer composites, reduce energy demands in composite processing (e.g. infrared curing to harden the resins), for the automotive and aerospace industry. Similarly, The SUNSHINE project investigates GO production and functionalization to improve flame retardancy in thermoplastic composites for printed electronics and other sectors. The projects involve some of the largest developers and producers of GO in Europe.

The presentation will explain SSbD practices that are being developed and implemented in these projects for the processing, production and integration of GBMs in advanced composites.

6.05.P-Tu450 Methodological Approaches and Applications for Early TRL SSbD: Case Study on Upconverting Particles Used in Biocidal Coatings

***Merve Tunali** and Bernd Nowack, EMPA - Swiss Federal Laboratories for Materials Science and Technology, Switzerland*

The Safe and Sustainable by Design framework can be applied at any stage; from the innovation and design phase to the fully developed phase. Its iterative approach encourages the assessment to be improved as more data, and certainty become available during the innovation process. For a fully developed SSbD, high level of data is required. Although SSbD is possible for early Technology Readiness Levels (TRLs), more solid approaches are needed to address the data limitations at these stages. On the other hand, biocides, widely used in healthcare, food safety, and agriculture present challenges in applying SSbD due to their functionality that also provide benefits. An example of an early TRL biocide is upconverting particles, which convert lower-energy light into higher-energy UV radiation through a process called upconversion. Rare earth element containing materials (or hosts) efficiently perform this conversion. Recently, Pr^{3+} doped materials were reported to efficiently emit in the UV range which makes them useful to be used as biocides. In general, the SSbD framework with some specific considerations was followed throughout the study, applying a recently developed biocide-specific SSbD framework. First, the specific data requirements and gaps were identified for each step. Secondly, various methodological approaches were evaluated and then adjusted where needed in order to address these needs, focusing on ways to minimize gaps and effectively generate the required data that fits the specific chemical. Lastly, the case study of upconverting particles was applied to demonstrate the feasibility of conducting SSbD at early TRLs. Our results highlight the need for refining SSbD methodologies for early TRL applications, ensuring that early-stage chemicals can be assessed for safety and sustainability. This work provides a foundation for integrating early TRL chemicals into sustainable innovation processes.

Disclaimer/Disclosure: The funding from the following projects is acknowledged: NOVA Next Generation Bioactive Nanocoatings funded by the European Union (Grant Agreement 101058554) and Swiss State Secretariat for Education, Research and Innovation.

6.05.P-Tu451 Safe and Sustainable by Design Strategies: A Hotspot-based Approach for Advanced Materials

Sarah Devecchi[1], *Arianna Livieri*[2], *Lisa Pizzol*[1], *Alex Zabeo*[1], *Stella Ivanova Stoycheva*[3], *Elena Semenzin*[2] *and Danail Hristozov*[4], *(1)GreenDecision S.r.l., Italy, (2)Ca' Foscari University of Venice, Italy, (3)Yordas Group, Germany, (4)Emerge Ltd, Bulgaria*

The Safe and Sustainable by Design (SSbD) framework for chemicals and materials was established to guide the transition envisioned by the European Green Deal Chemical Strategy for Sustainability to a toxic-free environment. It was developed within the EC Joint Reserch Centre s and further described in the European Commission s (EC) Recommendation for establishing a European assessment framework for SSbD. To operationalize this framework, the H2020 SUNSHINE project has developed a tiered SSbD assessment methodology, which was tested in a suite of advanced multi-component nanomaterials. This approach enables the assessment of safety and sustainability aspects at each stage of product development from a lifecycle perspective. Tier 1 consists of a qualitative self-assessment questionnaire designed to evaluate the early stages of R&D and product optimization within the innovation process. The results highlight critical "hotspots" concerning safety and sustainability across the entire lifecycle of the target materials. In Tier 2, a more comprehensive and detailed analysis is conducted to address and further investigate these identified concerns prior to their release on the market. This is done through Chemical Safety Assessment, Lifecycle Assessment, Lifecycle Costing, and Social Lifecycle Assessment methodologies. The result is a holistic Life Cycle Sustainability Assessment of the materials / products investigated. Tier 2 played a crucial role in validating the results from Tier 1 and in addressing the identified "hotspots." This tiered approach was applied to four SUNSHINE industrial case studies through an iterative process. The findings demonstrate that Tier 1 was highly effective in supporting the early stages of material development by identifying potential safety and sustainability challenges during the R&D phase, when adjustments to the production process were still possible and cost-effective, and there was flexibility in choosing alternative design options. This has highlighted the added value of the SUNSHINE SSbD approach in enabling companies to assess the safety and sustainability performance of their products in a straightforward, targeted, and cost-effective way. This approach can significantly enhance the competitiveness of these industries in the market, while also driving the development of more environmentally friendly nanotechnologies that offer substantial societal and economic benefits.

Disclaimer/Disclosure: This work has been carried out under the SUNSHINE project grant agreement No 952924

6.05.P-Tu453 Engaging Stakeholders and Applying Safe and Sustainable by Design (SSbD) Principles in the PROTEUS EU Project

Cecilia Askham, ***Valentina Helen Pauna***, *Rannva Danielsen and Anna Woodhouse, NORSUS, Norway*

The initial focus of SSbD has been on chemicals, this study will apply the application of SSbD principles and LCSA to evaluate a novel production method in the context of kelp harvesting and biorefining, emphasizing cross-disciplinary collaboration, transparent communication along the value chain, and an iterative scientific process throughout the EU funded project: PROTEUS. The integration of these dimensions within the SSbD framework will be supported by stakeholder involvement and data transfer between industry and research partners to foster shared understanding and alignment on sustainability and safety priorities.

The framework presented integrates SSbD and LCSA. As the project progresses, experience and interactions between stakeholders will result in the development of this framework through an iterative process. The application of this SSbD and LCSA framework to a value chain where the innovation is the reduction (or removal) of hazardous chemicals means that it is not immediately obvious what benefits are derived from using an SSbD framework, beyond documenting the improvements possible with the innovation being developed. The authors maintain that there are benefits in integrating these approaches that can also be applied to systems where a value chain innovation is to be realised that reduces, or eliminates chemical hazard. The benefits of this approach will be explored and documented during the PROTEUS project. Stakeholder engagement will initially involve the value chain actors that are partners in the EU Horizon project. However, as the work progresses further stakeholders will be involved. The work presented will show the stakeholder involvement steps planned during the Proteus project timeline.

This work aims to highlight the potential of LCSA as a cornerstone for implementing SSbD principles in innovative production processes. By facilitating interdisciplinary collaboration and aligning diverse stakeholder interests, LCSA supports the paradigm shift towards safe and sustainable innovation. Future efforts in the Proteus project will focus on refining the LCSA/SSbD framework, engaging stakeholders and continuous iterative improvement.

Disclaimer/Disclosure: Funding from Grant agreement ID: 10115696, Horizon Europe

6.05.P Implementing Holistic SSbD Approaches to Chemicals and Materials: What Do Academia, Industry, Regulators and Policymakers Propose?

6.05.P-Tu438 Exposure Assessment Along the Life Cycle of Nanocomposites

Gunther Van Kerckhove[1]*, Amaia Soto Beobide*[2]*, George Voyiatzis*[2]*, Rudolf Bieri*[3]*, Kevin Sparwasser*[3]*, Konstantinos Andrikopoulos*[2]*, Aleksander Jandric*[4]*, Florian Part*[4]*, Marilyn WONG*[4]*, Anna Pavlicek*[4] *and Zoltan Szakacs*[3]*, (1)OCSiAl Europe Sarl, Luxembourg, (2)Foundation for Research and Technology Hellas-Institute of Chemical Engineering Sciences (FORTH), Greece, (3)STAT PEEL, Switzerland, (4)BOKU University, Austria*

Carbon nanotubes in general have outstanding properties that enable new applications such as high-performance concrete, super capacitors, sensors, improved conductive electrodes and inks, polymer nanocomposites, etc.. In polymers, the carbon nanotubes are used as additives to reinforce and enhance mechanical properties or to enable electrical and thermal conductivity. However, rigid, stiff and thin multi-wall carbon nanotubes can present asbestos-like hazards if they are released and inhaled, for example through abrasion from products. To minimize health risks as far as possible, the aim is to optimise their design according to the principle of Safe and Sustainable by Design, with a short length and low stiffness to enable them to be transported by macrophages in the lungs. We propose that this can be achieved with single-wall carbon nanotubes. Yet, this hypothesis is to be confirmed in release and toxicity studies, for which release, and more toxicity studies are still needed. In this context, we conducted two case studies to investigate possible possible released of single-wall carbon nanotubes from polymer nanocomposites. Potential exposure to airborne single-wall carbon nanotubes was studied during two laboratory-scale case studies of epoxy resins and lithium-ion batteries containing a Single wall carbon nanotube type in the polymer matrix and conductive electrode material, respectively. The single-wall carbon nanotubes, marketed under the brand name TUBALL, exhibits a distinctive morphology and behaviour during the life cycle stages in comparison with other carbon nanotube types. This renders some standardised test models inapplicable. The data generated from the case studies conducted under the European Commission projects DIAGONAL and SUNSHINE for the purposes of exposure assessment and Safe and Sustainable by Design indicate that the nanomaterial TUBALL is safe for use. To further confirm these findings, it is important to assess all the life cycle stages of single-wall carbon nanotubes and their environmental pathways and potential exposure routes. Regarding Safe and Sustainable by Design, the objective is to ensure responsible and safe use with meaningful risk management.

Disclaimer/Disclosure: The 2 EU funded projects mentioned in the presentation has received funding from the European Union s Horizon 2020 research and innovation programme under grant agreement No 952934 (SUNSHINE) and No 953152 (DIAGONAL).

6.05.P-Tu439 Implementation of Safe and Sustainable by Design (SSbD) Approach in the Development of Bio-based Products

Ronnie Juraske[1]*, Joan Berzosa Corbera*[2] *and Oliver Spaniol*[1]*, (1)knoell Germany GmbH, Germany, (2)knoell Iberia S.L., Spain*

Safe and Sustainable by Design (SSbD) is a central component in the European Chemicals Strategy for Sustainability and has the potential to be the tool to support industry through innovation of new products in the transition towards climate neutrality and a less toxic environment. However, a common understanding of what SSbD is in concept detail and in practice is still under discussion and development. In this study, we examine the applicability and effort for implementation of the SSbD framework to several bio-based products and materials across several industrial sectors. In our assessment, we include Hazard Assessment looking at the intrinsic properties of the compound or material in order to understand its hazard profile (human health, environment and physical hazards). Human Health and Safety Assessment looking at the adherence of the process to EU directives or regulations, Environmental and Human Health Risk at the final application or material looking at whether the use of a compound or material in its final application poses any risk to human health or the environment. Further, Environmental Impacts Evaluation along the entire life cycle, covering the assessment of the environmental sustainability aspects of the compound or material in question, focusing on its product environmental footprint. Finally, and complementing all the above activities, a semi-quantitative social life cycle assessment (sLCA,), based on the UNEP SETAC recommendations and the recently published ISO standard, in the key impact categories: employment, occupational health and safety, community well-being, and societal benefits will be conducted. Where possible, existing components of the Partnership for the Assessment of Risks from Chemicals (PARC) SSbD toolbox were taken into account in our study and further tool elements will be incorporated into our assessment upon integration into the toolbox. In order to determine the potential environmental benefits of bio-based products and materials, a preliminary assessment has been performed, based on an extensive review of LCA studies complemented by information from commercial LCA databases. In this analysis, the favorable environmental performance of bio-based products has been proven by comparing it with conventional production.

6.05.P-Tu440 A Safe & Sustainable by Design R&D Pipeline Using In Silico Methodology

Gaspard Levet[1]*, Franklin Bauer*[1]*, Carole Charmeau*[2]*, Nicolas Blouin*[3]*, Jasper Smets*[3]*, Sophie Jia*[4]*, Stephanie Quijano*[4]*, Daniel Arrieta*[4] *and Paul Thomas*[1]*, (1)KREATiS, France, (2)KU Leuven, France, (3)Chevron Phillips Chemical, Belgium, (4)Chevron Phillips Chemical, United States*

As we move towards the framework of Safe & Sustainable by Design (SSbD) products, companies increasingly incorporate environmental and human health protection considerations into their Research & Development (R&D) pipeline. As a result, New Approach Methodologies (NAM) are required to process, generate or predict (eco)toxicological and environmental effects of newly discovered families of compounds. Over the years, in silico predictions have garnered more recognition thanks to a greater understanding of the available methods as well as significant improvements in the depth and versatility of the tools now on the market. Use of in silico methods, (quantitative) structure activity relationship (Q)SAR model, to predict the (eco)toxicity and/or environmental fate of a substance is the logical choice to identify new compounds due to the speed and relative low cost when bulk predictions of numerous substances are required. A project requested by Chevron Phillips Chemical was undertaken by KREATiS to assess the toxicological effects of a wide range of chemicals of interest. Based on both technical and economical considerations, it was decided to focus on the most critical effects for human health: carcinogenic, mutagenic and reprotoxic (CMR) profile and skin sensitisation The first phase of the project was to group substances into chemical families based on structural and mechanistic insight. The second phase was the prediction of CMR and skin sensitisation for selected substances from each group, using available (Q)SAR tools and an in-depth review of these candidates. In the third phase, newly designed substances as well as high potential candidates previously grouped in high interest categories were reviewed. The latter having been characterized as having properties of relatively low concern for human health. Thus, using a battery of predictive in silico tools to estimate the relative toxicity of a large batch of promising compounds in the early-stage of R&D can help screen for the less desirable compounds and identify the most promising substances. A full scheme on how this was achieved is described in this poster.

6.05.P-Tu441 Redesigning for the Future: Applying Safe and Sustainable by Design (SSbD) Principles in High-Impact Chemical Industries

Matiss Reinfelds[1]*, Josephine Steck*[2]*, Cecile Philippot*[2]*, Wendel Wohlleben*[3]*, Martin Himly*[4] *and Caitlin Ahern*[1]*, (1)BioNanoNet Forschungsgesellschaft mbH, Austria, (2)Univ. Grenoble Alpes, CEA, Liten, France, (3)BASF SE, Germany, (4) University of Salzburg, Austria*

Adopting Safe and Sustainable by Design (SSbD) principles presents challenges for companies, requiring a shift from market-ready products back to pre-market R&D stages. This challenge is intensified by a complex and evolving regulatory landscape, especially in sectors like food contact materials, aviation, and pharmaceuticals. Without clear incentives, companies often hesitate due to high R&D costs, potential new regulatory approvals, and the risk that minor product changes might lead to customer rejection and financial losses.

The SSbD draft framework by the Joint Research Centre (JRC) provides a structured yet inherently stepwise approach. This sequencing can hinder efficient data integration, as data from each step must be combined across stages, often creating lengthy assessments. Additionally, data are often unavailable, immature, non-comparable, outdated, or incomplete. SSbD assessments span numerous disciplines, and no single expert covers all the knowledge required. A critical question is whether SSbD can be made more accessible for industry. Specifically, could product developers, even without deep SSbD expertise, use simplified tools to identify essential tasks and expert inputs, lowering the activation barrier for SSbD implementation without unrealistic black box expectations?

Our work demonstrates the SSbD framework's applicability by developing alternatives for three key chemical classes plasticizers, flame retardants, and surfactants progressing from Technology Readiness Level (TRL) 6 to incorporation in consumer goods at TRL 7. Central to our approach is exploring interconnections between SSbD's five steps, from initial safety assessments to broader sustainability

evaluations, and visualizing these links to support effective tool selection across SSbD stages.
An overarching question remains: would an SSbD certification a "seal" of safety and sustainability justify a higher product price for consumers? For companies, SSbD investment requires more than regulatory compliance it demands alignment of sustainability efforts with market acceptance. How much standardization of SSbD is needed to create an incentive for the value chain? By examining whether such efforts could bridge the gap between innovation and economic viability, we aim to address the initial hesitations companies face. Early findings from this ongoing work will be presented, highlighting the holistic application of SSbD in redesigning established products.

Disclaimer/Disclosure: This work has received funding from the European Union s Horizon Europe research and innovation programme under grant agreement n°101177608 (PLANETS).

6.05.P-Tu442 Screening Sustainability Assessment of Innovative Bio-Based Solution for Art Restoration

***Martina Menegaldo**[1], Elisa Giubilato[2], Lisa Pizzol[2], Elena Badetti[1] and Elena Semenzin[1], (1)Ca Foscari University of Venice, Department of Environmental Sciences, Informatics and Statistics, Italy, (2)GreenDecision S.r.l., Italy*

Within the HEU GREENART project, an assessment approach was developed to evaluate the safety and sustainability of innovative solutions for art restoration, including protective coatings, foams and packaging materials, consolidants, gels and cleaning fluids, and green tech sensors. This approach, developed taking in consideration the Safe and Sustainable by Design (SSbD) Framework and the Nanorestart Framework, is structured into three iterative stages. Stage 1 involves the Hazard Assessment of innovative ingredients and formulations. Stage 2 includes a Screening Sustainability Assessment. Stage 3 focuses on assessing the sustainability performance of the most promising solutions identified in the earlier stages, through Life Cycle Assessment (LCA). This study focuses on the stage 2 of the GREENART approach: the Screening Sustainability Assessment, developed during the second year of the project and already used to guide the decision-making process. This assessment is conducted through a questionnaire structured around three main aspects: Functionality, Safety and Sustainability. The three aspects are assessed across the entire life cycle of GREENART's innovative products and benchmarks. Each aspect is assessed through specific criteria, providing measurable indicators of sustainability performance. The criteria help in determining the significance and impact of each aspect within the life cycle stages. Finally, the assessment incorporates targeted questions designed to evaluate compliance with the established criteria. Each question has five possible answers, representing the level of satisfaction with a specific product solution, ranging from "excellent" to "bad". These scores are then averaged to visualize the overall results across the different life cycle stages and sustainability aspects.
The safety aspect is assessed by combining the Hazard Classification from Stage 1 of the GREENART approach with an Exposure Classification, inspired by the ProScale method, within the GREENART Control Banding Matrix.
The results of the Screening Sustainability Assessment will be presented for one case study, selected from GREENART s innovative products and related benchmarks.
This approach aligns with the SSbD framework, ensuring compliance with evolving European and international chemical safety regulations while continuously improving the safety and sustainability profile of these products.

6.05.P-Tu443 From Ambition to Action: Navigating Obstacles and Opportunities of ‘Safe and Sustainable by Design’

***Joanke van Dijk**[1], Anezka Sharma[2], Bernd Nowack[1], Zhanyun Wang[1] and Martin Scheringer[3], (1)EMPA - Swiss Federal Laboratories for Materials Science and Technology, Switzerland, (2)RECETOX, Masaryk University, Czech Republic, (3)Institute of Biogeochemistry and Pollutant Dynamics (IBP), ETH Zurich, Switzerland*

With the introduction of Safe and Sustainable by Design (SSbD) concept, momentum is being created in the European Union (EU) to shift from reactive (mis-)management of chemicals and materials to a more proactive design and assessment approach to prevent pollution issues. The concept holds the potential to steer the innovation process toward a green and sustainable industrial transition, promote the reduction and substitution of substances of concern, and minimize health and environmental impact throughout the life cycle of chemicals and materials. To operationalize the SSbD concept, the European Commission has recommended a framework, but many questions remain open regarding its feasibility and implementation. The aim of this work was to deepen the current discussion on SSbD towards an effective operationalization. We critically analyse and discuss how the by design aspect and the safety and sustainability assessments of SSbD constitute a unique opportunity for the green transition. We evaluate obstacles and highlight opportunities of operationalizing the EU SSbD framework in a refined manner. Our analysis indicates that the EU SSbD framework, despite its potential, is unlikely to fully achieve its ambitions in its current form. In particular, suitable assessment methods are not yet available for many aspects, and the complexity and data requirements of the SSbD framework may hinder widespread adoption or result in paralysis by analysis. Moving forward, a more realistic, agile framework, accompanied by clear, simplified methods and robust support for stakeholders, should be developed to ensure the SSbD principles are fully integrated into practice, leading to truly safer and more sustainable chemicals and materials. We further highlight opportunities to address identified gaps, establish an improved framework, and enhance its operationalization.

Disclaimer/Disclosure: Acknowledgement - JvD was supported by the Swiss Federal Office for Public Health. ZW acknowledges funding from the European Union s Horizon 2020 research and innovation programme under grant agreement No. 101036756, project ZeroPM: Zero pollution of persistent, mobile substances. AS obtained financial support of the provider Grant Agency of Masaryk University within the project MUNI/R/1381/2023 and was supported by the RECETOX Research Infrastructure (LM2023069) financed by MEYS CR.

6.05.P-Tu444 Chemical Assessment Frameworks and their Alignment to the EC Safe and Sustainable by Design Framework: An Initial Exploration

*Maria Rachele Sesterzi[1], **Martina Menegaldo**[1], Lisa Pizzol[2], Elisa Giubilato[2], Andrea Casini[3], Giovanna Poggi[3], David Chelazzi[3], Piero Baglioni[3] and Elena Semenzin[1], (1)Ca Foscari University of Venice, Italy, (2)GreenDecision S.r.l., Italy, (3)CSGI and Department of Chemistry Ugo Schiff, University of Florence, Italy*

The HEU GREENART project proposes innovative chemicals and materials for the conservation and restoration of Cultural Heritage. All GREENART solutions are assessed in terms of safety and sustainability performance. The assessment begins with the use of green metrics by product developers. In particular, the Global Score method from CSGI is a tool to evaluate chemicals, specifically solvents and surfactants. It incorporates available green metric scores, derived from several chemical frameworks (i.e., CHEM 21, Sanofi, GSK, Pfizer, Astrazeneca). Following this, a more thorough evaluation is underway in the project to assess the safety and sustainability of the GREENART solutions throughout their entire lifecycle. This novel approach comprises a Hazard Assessment, a Screening Sustainability Assessment and a full Life Cycle Assessment (LCA). The JRC s Safe and Sustainable by Design (SSbD) Framework and the Nanorestart Framework are at the foundation of this approach. The goal of this study was to explore the chemical frameworks considered in the Global Score method and to evaluate their alignment with the SSbD Framework in terms of procedure and design principles. The evaluation proceeded gradually, starting from the SSbD principles proposed to support product developers during the design phase. These include aspects related to safety and resource use, considering the whole life cycle, and related indicators. Some of these indicators are also evaluated in the chemical frameworks included in the Global Score method. Next, the alignment of the green chemistry indicators from chemical assessment frameworks with the five steps of the SSbD framework is evaluated. The highest alignment has been observed in Step 1 for Hazard Assessment and Step 2 and 3 for Safety Assessment. Indeed, most green chemistry indicators consider intrinsic hazardous properties of chemicals and potential risks for workers during production and final application phases. Step 4 for Environmental Sustainability Assessment is only partially covered by the chemical frameworks under study. Although some specific indicators exist for LCA, it is unclear how the LCA behind them is performed, and which data are considered. Step 5 for Social and economic sustainability assessment is the least addressed. This work is expected to support the application of principles that extend beyond traditional green chemistry, aiming to enable science-based decision making within the SSbD era.

6.05.P-Tu445 Application of SSbD Concepts to the Development of Bio-based Epoxy Compounds for Polymer Coatings

***Andy Booth**[1], Mari Creese[1], Lisbet Sorensen[1], Amaia Igartua[1], Kamal Azrague[2], Francesca di Bartolomeo[3], Juan Yang[3] and Mihaela Tanase-Opedal[4], (1)SINTEF Ocean, Norway, (2)SINTEF Community, Norway, (3)SINTEF Industry, Norway, (4)RISE-PFI, Norway*

Two?component epoxy represents a developed group of chemicals having a broad use in building and coating applications worldwide. Although they contribute to sustainability by protecting and expanding lifetime of products and installations, they are almost exclusively derived from fossil resources and based on compounds like bisphenol A (BPA) that present a threat to health and the environment. The NordiCoats project aims to lay the basis for the development of new epoxy?based solutions that are bio?based, safer in use, potentially recyclable, and with performance levels close to relevant benchmarks.

This is achieved by assessing the sustainability and safety of the new bio?based compounds and formulations. Here, we present a comparison of the aqueous leaching of 20 different candidate coating formulations and link this to the bulk material composition to identify those chemicals which are preferentially released. Non-target and suspect screening were performed using both thermal desorption-pyrolysis GC-MS and GC×GC-MS on the bulk coating material and aqueous leachate solvent extracts. By using a combination of known ingredients and mass spectral library matching to provide lists of the main components in the bulk coating materials and leachates, existing environmental toxicity and human toxicity data were retrieved from databases and used to perform a risk assessment. This approach allowed us to identify those coating components that exhibited the highest leaching potential and toxicity, thereby indicating which coating formulations had the least impact on humans and the environment.

6.05.P-Tu446 A Multi-actor Approach to Facilitate the SSbD Implementation in SURFs UP Bio-based Value Chains

Socorro Vazquez-Campos[1]*, Virginia Cazzagon*[1]*, Ruben Martínez*[1]*, Ana Candalija*[1]*, Camilla Delpivo*[1] *and Sofie Lodens*[2]*, (1)Leitat Technological Center, Spain, (2)Bio Base Europe Pilot Plant vzw, Belgium*

Currently only 4% of the surfactant market share consists of compounds that are 100% based on biomass (fully biobased surfactants), while there is an urgent need for non-hazardous Safe and Sustainable by Design (SSbD) biosurfactants (BSs). The biosurfactant market is expected to grow at a CAGR (Compound Annual Growth Rate) of between 5.2 and 10.5% between 2022 and 2028. However, the diversity of the currently available safe and sustainable biosurfactants is not at all sufficient to meet the market needs: diversity is key. SURFs UP proposes a (integrated) combination of biological & green chemical production routes from (waste) biomass second generation (2G) feedstocks and following SSbD criteria which will allow a dramatic transformation of the surfactant market by offering the broad diversity of safe and sustainable alternatives at a reasonable cost that the market is looking for. SURFs UP will bridge this gap by demonstrating optimized and cost-efficient processes for 9 SSbD biosurfactant products that will be formulated in prototypes in home- and personal care and agrochemical applications. These ingredients will be fully characterized and evaluated according to the EC SSbD Framework criteria. Finally, the production of SSbD BSs will be scaled up and used to demonstrate prototype formulations in home care, personal care, and biopesticide applications. SURFs UP project activities implement a multi-actor approach according to the quadruple helix innovation model, where science, policy, industry, and society are involved in the technology development and innovation process. This ensures that all the relevant actors and end-users in the bio-based value chain are appropriately involved. In SURFs UP a decision-making process will be implemented (e.g., stage to gate) along the supply chain to promote the integration of the SSbD principles in all stages of product development, use and end-of-life. We ensure an active and iterative flow of information from the start of the project, with all the actors involved in the products development, through meetings and workshops. Important information will be produced throughout the project which will be analyzed in an integrated way.

Disclaimer/Disclosure: The project is supported by the circular bio-based Europe Joint undertaking and its member. Funded by the European Union. 6.05.P-Tu447 The SUNRISE SSbD Integrated Impact Assessment Framework

Lisa Pizzol[1]*, **Arianna Livieri***[2]*, Alex Zabeo*[1]*, Sarah Devecchi*[1]*, Alberto Katsumiti*[3]*, Andrea Brunelli*[4]*, Elisa Giubilato*[4]*, Michael Saidani*[5]*, Konstantina Koutsiara*[6]*, Carlos Fito*[7]*, Jamea Baker*[8]*, Blanca Suarez Merino*[8]*, Stella Ivanova Stoycheva*[9]*, Yasemin Ertugrul*[9]*, Hubert Rauscher*[10]*, Irantzu Garmendia Aguirre*[10] *and Danail Hristozov*[11]*, (1)GreenDecision S.r.l., Italy, (2)GreenDecision s.r.l., Italy, (3)GAIKER Technology Centre, Basque Research and Technology Alliance (BRTA), Zamudio, Spain, (4) Ca' Foscari University of Venice, Italy, (5)LIST Luxembourg Institute of Science and Technology, Luxembourg, (6)HYPERTECH SA, Greece, (7)ITENE Parque Tecnologico, Spain, (8)TEMAS Solutions GmbH, Switzerland, (9)Yordas Group, Germany, (10)European Commission, Joint Research Centre (JRC), Italy, (11)Emerge Ltd, Sofia, Bulgaria*

As part of the European Green Deal, the Chemicals Strategy for Sustainability and the Zero Pollution Action Plan highlight the critical need for a Safe and Sustainable by Design (SSbD) approach to chemicals and materials. To drive this transformation, the European Commission (EC) has recommended the establishment of a European assessment framework for SSbD of chemicals and materials, based on a holistic approach developed by the EC's Joint Research Centre. To facilitate the practical adoption of the EC-JRC framework by stakeholders, particularly within the industry, the Horizon Europe SUNRISE project has been funded to develop integrated methodologies for assessing the health, environmental, social, and economic impacts of products enabled by advanced materials (AdMa). The SUNRISE project combines the bottom-up development of methods and tools for assessment of health, environmental, social and economic impacts with their top-down integration in an overarching Integrated Impact Assessment Framework (IIAF). This framework is designed to support SSbD decision-making along supply chains and lifecycle stages of AdMa and their products. The process of developing and testing the IIAF in cocreation with the stakeholders within a trusted real-world environment will improve our understanding of stakeholders needs, perceptions and relevant SSbD aspects to be considered, along with potential safety and sustainability trade-offs. This new knowledge will be transferred to regulators and policy makers at EU and national level to support them in the implementation of SSbD-related policies for chemicals and materials. The IIAF is composed of 4 assessment Tiers, fully aligned to the 5 steps of the EC-JRC SSbD framework, where each tier corresponding to an integrated methodology (supported by a toolbox) for health, environmental, social and economic impact assessment targeting different groups of users at different stages of the innovation process and requiring a different level of data and expertise. The implementation of the IIAF will ensure better regulatory compliance for AdMa based products and can have an impact on shortening the time of new materials/products to reach the market, thereby supporting the Green Deal policy objectives for the transformation of the EU into a modern, resource-efficient and competitive economy.

6.05.P-Tu448 SEARCULAR: Towards the Practical Implementation of a Circular Economy for Fisheries

*Mikel Isasi-Vicente[1], Paule Espa a[1], Asier Asueta[1], Vanesa Benito[1], Maria Jose Suarez[1], Elsa Cuende[2], Iker Zudaire[2], Maitane Grande[2], Joana Larreta[2], Carolina Alonso[2], Maria C. Uyarra[2], Marga Andres[2], Lisbet Sorensen[3], Anja Alvestad[3], Sigrid Hakvaag[3], Andy Booth[3], Boris Dresen[4], Daniel Maga[5], Christina Galafton[4], Venkat Aryan[4], Mona Arnold[6], Katri Behm[6], Noora Harju[6], Naia Gonzalez[7], Roger Larsen[8], Knut Steffen Solvaag[9], Gala Moreno[10], Hilario Murua[10], Francisco Campuzano[11], Paula Salge[11], Felipe Goni de Cerio[1], **Alberto Katsumiti**[1] and Oihane C. Basurko[2], (1)GAIKER Technology Centre, Basque Research and Technology Alliance (BRTA), Spain, (2)AZTI Marine Research, Basque Research and Technology Alliance (BRTA), Spain, (3)SINTEF Ocean, Norway, (4)Fraunhofer Institute for Environmental, Safety, and Energy Technology UMSICHT, Germany, (5)Fraunhofer Institute for Environmental, Safety, and Energy Technology UMSICHT, Belgium, (6)VTT Technical Research Centre of Finland ltd, Finland, (7)SARETU RECYCLING S.L., Spain, (8)The Arctic University of Norway, UiT, Norway, (9)SELSTAD AS, Norway, (10)International Seafood Sustainability Foundation (ISSF), United States, (11)Colab Atlantic, Portugal*

Every year, more than eight million metric tonnes of plastic are discharged into the oceans. Among these, 600,000 to 800,000 metric tonnes of Abandoned, Lost, or Discarded Fishing Gear (ALDFG) contribute significantly, representing about 10% of marine litter by weight, according to the UN Food and Agriculture Organization. Studies indicate that ALDFG makes up to 70% of all oceanic macroplastics mass, and eventually break down into micro- and nanoplastics, posing serious risks to marine ecosystems. The SEARCULAR project addresses these environmental challenges by creating Safe and Sustainable by Design (SSbD) circular solutions for fishing gear, aimed at reducing both marine litter and the formation of micro- and nanoplastics. SEARCULAR's work includes developing four sustainable, near-market, circular solutions to reduce the ecological impact of fishing gear. Three of these initiatives focus on replacing conventional plastics with SSbD alternatives:

1. Creation of dolly ropes made from recycled polyamide (rPA) derived from discarded fishing nets.
2. Development of seine ropes from certified marine-biodegradable materials.
3. Eco-design of drifting Fish Aggregating Devices (dFADs) made of organic materials that biodegradate at marine environments.

The fourth strategy addresses end-of-life (EoL) fishing gear management by promoting a replicable system at harbors for processing this gear into reusable plastic through pyrolysis, thus converting discarded plastic into a resource.

These innovative approaches aim to support the fishing industry and related sectors in reducing their environmental footprint by embracing circular strategies, utilizing numerical modeling, and establishing replicable EoL management practices. The SEARCULAR project will rigorously assess and validate the sustainability of each alternative, engaging stakeholders from industry, science, policy, and non-governmental organizations (NGOs) to facilitate acceptance and behavioral change within the fishing sector. Additionally, SEARCULAR will inform policymakers of critical challenges and best practices to help enable the broad adoption of sustainable practices across Europe. SEARCULAR has received

funding from the European Union's Horizon Europe research and innovation programme under grant agreement No. 101112852.

6.05.P-Tu449 Key Performance Indicators in SSbD: A Transparent and Data-Driven Methodology

Irini Furxhi *and Anna Costa, CNR ISSMC, Italy*

"The Safe and Sustainable by Design (SSbD) framework by the Joint Research Centre (JRC), aims to establish criteria and evaluation procedures for chemicals, (nano)materials, producs, and processes. This framework emphasizes the assessment of the entire life cycle of compounds, incorporating human and environmental safety aspects alongside environmental and economic sustainability dimensions. The overarching goal is to stimulate sustainable research and innovation that transcends current regulatory requirements.

ASINA project employed the SSbD framework in nanotechnology case studies to identify material design alternatives early in the innovation process. This approach reduced the potential for hazardous material release and minimized hazard levels, while ensuring functional performance for intended applications. This presentation will take the concept further by introducing a data-driven methodology for merging diverse datasets to derive a unified indicator. Specifically, we will:

1. Present measurable, quantitative, and qualitative indicators, defined for various aspects (e.g., health and environmental impact) and measured through experimental or modeling methods.
2. Highlight the role of Key Decision Factors (KDFs), which are modifiable by the designer to influence the final indicators, enabling flexibility in the "re-design" process.
3. Explore Key Performance Factors (KPFs), which influence outcomes but are not under the designer’s control.

By providing indicators and linking them to their respective KDFs and KPFs, this methodology offers a robust starting point for future SSbD implementations and data management strategies. The approach ensures transparency and fosters alignment with ongoing and future projects striving toward similar objectives, inspiring sound scientific practices. Ultimately, by developing integrated indicators, we aim to streamline the SSbD evaluation process, supporting a harmonized, data-driven approach to sustainable innovation across material and process life cycles.

Disclaimer/ Disclosure (optional): The authors would like to acknowledge the financial support from the European Union’s Horizon 2020 research and innovation programme under grant agreement No. 862444, No. 101137809 and the HORIZON MSCA-2022-PF-01–01 Programme, grant N°101103082.

6.05.P-Tu450 Methodological Approaches and Applications for Early TRL SSbD: Case Study on Upconverting Particles Used in Biocidal Coatings

Merve Tunali *and Bernd Nowack, EMPA - Swiss Federal Laboratories for Materials Science and Technology, Switzerland*

The Safe and Sustainable by Design framework can be applied at any stage; from the innovation and design phase to the fully developed phase. Its iterative approach encourages the assessment to be improved as more data, and certainty become available during the innovation process. For a fully developed SSbD, high level of data is required. Although SSbD is possible for early Technology Readiness Levels (TRLs), more solid approaches are needed to address the data limitations at these stages. On the other hand, biocides, widely used in healthcare, food safety, and agriculture present challenges in applying SSbD due to their functionality that also provide benefits. An example of an early TRL biocide is upconverting particles, which convert lower-energy light into higher-energy UV radiation through a process called upconversion. Rare earth element containing materials (or hosts) efficiently perform this conversion. Recently, Pr^{3+} doped materials were reported to efficiently emit in the UV range which makes them useful to be used as biocides. In general, the SSbD framework with some specific considerations was followed throughout the study, applying a recently developed biocide-specific SSbD framework. First, the specific data requirements and gaps were identified for each step. Secondly, various methodological approaches were evaluated and then adjusted where needed in order to address these needs, focusing on ways to minimize gaps and effectively generate the required data that fits the specific chemical. Lastly, the case study of upconverting particles was applied to demonstrate the feasibility of conducting SSbD at early TRLs. Our results highlight the need for refining SSbD methodologies for early TRL applications, ensuring that early-stage chemicals can be assessed for safety and sustainability. This work provides a foundation for integrating early TRL chemicals into sustainable innovation processes.

Disclaimer/Disclosure: The funding from the following projects is acknowledged: NOVA Next Generation Bioactive Nanocoatings funded by the European Union (Grant Agreement 101058554) and Swiss State Secretariat for Education, Research and Innovation.

6.05.P-Tu451 Safe and Sustainable by Design Strategies: A Hotspot-based Approach for Advanced Materials

Sarah Devecchi[1]*, Arianna Livieri*[2]*, Lisa Pizzol*[1]*, Alex Zabeo*[1]*, Stella Ivanova Stoycheva*[3]*, Elena Semenzin*[2] *and Danail Hristozov*[4]*, (1)GreenDecision S.r.l., Italy, (2)Ca' Foscari University of Venice, Italy, (3)Yordas Group, Germany, (4)Emerge Ltd, Bulgaria*

The Safe and Sustainable by Design (SSbD) framework for chemicals and materials was established to guide the transition envisioned by the European Green Deal Chemical Strategy for Sustainability to a toxic-free environment. It was developed within the EC Joint Reserch Centre s and further described in the European Commission s (EC) Recommendation for establishing a European assessment framework for SSbD. To operationalize this framework, the H2020 SUNSHINE project has developed a tiered SSbD assessment methodology, which was tested in a suite of advanced multi-component nanomaterials. This approach enables the assessment of safety and sustainability aspects at each stage of product development from a lifecycle perspective. Tier 1 consists of a qualitative self-assessment questionnaire designed to evaluate the early stages of R&D and product optimization within the innovation process. The results highlight critical "hotspots" concerning safety and sustainability across the entire lifecycle of the target materials. In Tier 2, a more comprehensive and detailed analysis is conducted to address and further investigate these identified concerns prior to their release on the market. This is done through Chemical Safety Assessment, Lifecycle Assessment, Lifecycle Costing, and Social Lifecycle Assessment methodologies. The result is a holistic Life Cycle Sustainability Assessment of the materials / products investigated. Tier 2 played a crucial role in validating the results from Tier 1 and in addressing the identified "hotspots." This tiered approach was applied to four SUNSHINE industrial case studies through an iterative process. The findings demonstrate that Tier 1 was highly effective in supporting the early stages of material development by identifying potential safety and sustainability challenges during the R&D phase, when adjustments to the production process were still possible and cost-effective, and there was flexibility in choosing alternative design options. This has highlighted the added value of the SUNSHINE SSbD approach in enabling companies to assess the safety and sustainability performance of their products in a straightforward, targeted, and cost-effective way. This approach can significantly enhance the competitiveness of these industries in the market, while also driving the development of more environmentally friendly nanotechnologies that offer substantial societal and economic benefits.

Disclaimer/Disclosure: This work has been carried out under the SUNSHINE project grant agreement No 952924

6.05.P-Tu452 Unlocking the Future: SSbD as the Sustainable Solution for the Life Science Industry

Athanasios Gkrillas[1]*, Karoline Wowra*[2]*, Winfried Bulach*[2]*, Alexandra Gastens*[2]*, Lidia Ceriani*[3]*, Erwan Saouter*[4] *and Florian Gruener*[2]*, (1)Merck Life Science BV, Belgium, (2)Merck Life Science KGaA, Germany, (3)Merck Life Science Srl, Italy, (4)Net-Zero Impact (SAS), France*

The European Union's Chemicals Strategy for Sustainability (CSS) aims to foster a toxic-free environment by promoting the "Safe and Sustainable by Design" (SSbD) framework for pre-market chemical assessments. This framework systematically evaluates the safety, environmental impact, and socio-economic sustainability of chemicals, encouraging redesign when performance does not meet SSbD criteria. Merck's Life Science business, with over 300,000 products globally, provides essential tools, high-quality chemicals, and consumables for research, biotechnology, and pharmaceutical development. However, the complexity of Merck s portfolio presents challenges for the immediate and comprehensive implementation of SSbD at scale, as it requires extensive data and expert evaluation.

To address this, we propose a flexible application of the SSbD framework as a solution-oriented approach for assessing the safety and environmental sustainability of both new and existing Life Science products, scaling the methodology based on data availability and product prioritization. To evaluate our effectiveness regarding data, tools, and methods, we conducted several SSbD case studies across various product types, including challenging categories like polymers and articles. We faced challenges such as limited acceptance of New Approach Methodologies (NAMs) to address data gaps, variability in safety scores due to different exposure tools, difficult acquisition of tonnage information, and data availability issues from suppliers affecting Life Cycle Assessment (LCA). We identified strategies and tools to overcome some challenges, while others require further dialogue with relevant stakeholders at the European level to enhance the SSbD framework. The high data demands of the SSbD framework necessitate a pragmatic, stepwise approach, particularly for low-volume and low-hazard chemicals. We

also advocate for a unified methodology and scoring system to facilitate meaningful comparisons across companies, improving the operationalization of the SSbD framework.
This work highlights the potential of the SSbD framework to enhance chemical safety and environmental sustainability in the Life Science sector while addressing the complexities of data requirements and model integration. Future enhancements and industrial-scale applications of the SSbD framework will be discussed, emphasizing the need for collaboration within the chemical industry to achieve sustainable solutions.

6.05.P-Tu453 Engaging Stakeholders and Applying Safe and Sustainable by Design (SSbD) Principles in the PROTEUS EU Project

*Cecilia Askham, **Valentina Helen Pauna**, Rannva Danielsen and Anna Woodhouse, NORSUS, Norway*
The initial focus of SSbD has been on chemicals, this study will apply the application of SSbD principles and LCSA to evaluate a novel production method in the context of kelp harvesting and biorefining, emphasizing cross-disciplinary collaboration, transparent communication along the value chain, and an iterative scientific process throughout the EU funded project: PROTEUS. The integration of these dimensions within the SSbD framework will be supported by stakeholder involvement and data transfer between industry and research partners to foster shared understanding and alignment on sustainability and safety priorities.

The framework presented integrates SSbD and LCSA. As the project progresses, experience and interactions between stakeholders will result in the development of this framework through an iterative process. The application of this SSbD and LCSA framework to a value chain where the innovation is the reduction (or removal) of hazardous chemicals means that it is not immediately obvious what benefits are derived from using an SSbD framework, beyond documenting the improvements possible with the innovation being developed. The authors maintain that there are benefits in integrating these approaches that can also be applied to systems where a value chain innovation is to be realised that reduces, or eliminates chemical hazard. The benefits of this approach will be explored and documented during the PROTEUS project. Stakeholder engagement will initially involve the value chain actors that are partners in the EU Horizon project. However, as the work progresses further stakeholders will be involved. The work presented will show the stakeholder involvement steps planned during the Proteus project timeline.

This work aims to highlight the potential of LCSA as a cornerstone for implementing SSbD principles in innovative production processes. By facilitating interdisciplinary collaboration and aligning diverse stakeholder interests, LCSA supports the paradigm shift towards safe and sustainable innovation. Future efforts in the Proteus project will focus on refining the LCSA/SSbD framework, engaging stakeholders and continuous iterative improvement.

Disclaimer/Disclosure: Funding from Grant agreement ID: 10115696, Horizon Europe

6.05.P-Tu454 Early-stage Application of the SSbD Framework on PFAS Alternatives for Textile and Packaging Sectors

*Elise Morel[1], Nina Jeliazkova[2], Federico Busio[3], Panagiotis Isigonis[3], Mathilde Legay[4], Imad Audi[4], Tamara Piocke[5], Somchith Niquee[5], Diana Dohlere[5], Erno Karjalainenf[6], Mika Vaha-Nissi[6], Timo Lappalainen[6], Paz Aragon Chivite[7], Ruth Garcia[7], miika nikinmaa[6] and **Blanca Suarez Merino**[1], (1)TEMAS Solutions GmbH, Switzerland, (2)IdeaConsult Ltd, Bulgaria, (3)Luxembourg Institute of Science and Technology (LIST), Luxembourg, (4)LGI Sustainable Innovation, France, (5)Fraunhofer ISC, Germany, (6)VTT, Finland, (7)Leitat Technological Center, Spain*
PFASes accumulate in ecosystems and cause severe health and environmental issues. In response, the European Union will be restricting PFASes by means of a REACH restriction (Restriction proposal currently under evaluation by the European Chemicals Agency (ECHA) committees). Balancing performance requirements with health and environmental considerations when developing PFAS-free coatings is a complex process that requires innovative approaches in both material science and product design. The main objective of the ZeroF project is to develop and validate two novel PFAS-free hybrid coating formulations; carbohydrate fatty acid esters (CFAEs) for both packaging and textiles and silicate-based organic-inorganic hybrid materials (ORMOCER®) for upholstery textiles. To obtain the desired omniphobicity, different strategies based on chemical modifications, the addition of performance additives and structuration effects have been studied. The project is using the Safe and Sustainable by Design (SSbD) framework published for chemicals and advanced materials by the Joint Research Centre to guide the design of these coatings along their development stages. In the early phase of innovation, safety,

sustainability and cost screenings of materials and chemicals envisaged for formulations (e.g. precursors, solvents, and additives) were conducted. Data gaps and limited applicability of in silico tools were challenging for the assessment of the PFAS-alternatives themselves. Complex modeling approaches (e.g. using mixture and transformation considerations) are deployed to overpass these challenges and will be complement by toxicity data generated for the most promising PFAS-alternatives using new approach methodologies at a later stage of the innovation. Together, these data should allow the risks for workers, consumers and the environment associated to PFAS-alternatives synthesis, processing, use and end of life to be compared to those estimated for PFAS. ZeroF combines SSbD, technical developments and modelling in iterative evaluations to create upholstery textile and food packaging prototypes that are safer and more sustainable while meeting the required oil and water barrier repellencies.

6.05.P-Tu455 How Can Innovation Management Support SSbD?

Nina Melander, *Research Institutes of Sweden, Sweden*

The Safe and Sustainable by Design (SSbD) framework is a transformative approach to innovation, embedding safety and sustainability into the design of chemicals and materials. Addressing the "triple crisis" of climate change, biodiversity loss, and pollution, it aligns innovation with societal, safety and environmental goals. However, operationalizing SSbD principles demands rethinking traditional innovation processes to integrate safety and sustainability alongside economic and functional performance, introducing new complexities and uncertainties.

Key challenges include managing trade-offs across safety, environmental, social, and economic dimensions, evaluating long-term impacts, and addressing stakeholder concerns from the design phase onward. While managing uncertainty is inherent in innovation, SSbD introduces novel uncertainties related to sustainability metrics, regulatory requirements requiring systematic and adaptive solutions.

Structured innovation management systems (IMS), such as those outlined in the ISO 56000 can guide alignment with organizational objectives through leadership commitment, strategic direction, operational planning, and continuous improvement. By integrating SSbD principles into an IMS, organizations could potentially foster a culture of innovation that prioritizes safety and sustainability.

The ISO 56000 series outlines eight principles that could support SSbD, for example realizing value, future-focused leadership, adaptability, and managing uncertainty. However, IMS frameworks can be complex, particularly for SMEs. To address this, the study will focus on a simplified model, 4F (Capability for Renewal). 4F focuses on monitoring external trends, managing internal resources, goals with purpose, and the innovation process.
By exploring synergies between ISO 56000 and SSbD, this work offers a first view into practical strategies for embedding safety and sustainability into innovation processes.

6.05.P-Tu456 Balancing the Unseen: Resolving Conflicts in Safe and Sustainable by Design Frameworks

Lasse Steffens *and Bernd Moritz Giese, Institute of Safety and Risk Sciences, University of Natural Resources and Life Science, Austria*

Contemporary research on Safe and Sustainable by Design (SSbD) approaches faces significant challenges due to a lack of coherent integration of the multifaceted dimensions of sustainability. These gaps create the risk of perpetuating contradictions within sustainability assessments, as the choice and application of indicators often depend on differently oriented conceptualizations of sustainability. To address these challenges, this research investigates conflicting parameter relationships within existing SSbD frameworks. Particular focus is placed on the dynamic interplay between environmental, economic, and social dimensions, aiming to identify areas where trade-offs or conflicting priorities emerge in practice. Such conflicts may result in assessments that overlook critical nuances, limiting their ability to guide sustainable design effectively. By bridging theoretical discourse on sustainability with practical applications, this analysis critically examines the foundations and limitations of current frameworks. Special emphasis is placed on understanding how the relationships between individual parameters such as resource efficiency, economic viability, and social equity affect the aggregation of indicators used in decision-making processes. Understanding these relationships is crucial for designing a robust and reflective SSbD assessment framework. It enables practitioners to anticipate and navigate inherent contradictions while fostering a balanced approach to sustainability that incorporates diverse priorities. Ultimately, this research aims to refine SSbD methodologies, enhancing their ability to guide the development of advanced materials and technologies in ways that genuinely align with sustainability's core.

6.05.P-Tu457 Application of the SSbD Framework in Bio-based Plastics: Lessons Learned from the BIORING Case Studies

Cyrille Durand[1]*, Blanca Suarez Merino*[1]*, Jovita Moreno*[2]*, Jorge Blanco-Cejas*[2]*, Vince Hop*[3]*, Andrea Porcari*[4] *and Elena Destro*[4]*, (1)TEMAS Solutions GmbH, Switzerland, (2)Universidad Rey Juan Carlos, Spain, (3)Process Design Center, Netherlands, (4)Associazione Italiana per la Ricierca Indusriale, Italy*

The BIORING project aims to develop a novel portfolio of renewable formulations for UV curable polyurethane biocoatings with optimal biodegradable and/or recyclable features for the construction, furniture, automotive sectors and beyond.
The application of the SSbD faces several challenges, including how to address criteria and data needs at the early stage of innovation. Within the BIORING innovation process, information during the early stages is also scarce, so partners used available foresight tools developed for AdMa to cover information gaps.
In this study we present cost effective approaches and tools applied for an early safety and sustainability assessment of the BIORING materials and processes.
The foresight tools Early4AdMa and LICARA Innovation Scan were used to perform safety, sustainability and cost/benefit assessments to cover steps 1-4 of the SSbD EU Framework at early innovation processes. The selected tools also enabled to identify uncertainties requiring further information later in the innovation process.
Then we conducted a preliminary LCA of the BIORING lab scale processes for an early SSbD step 4 assessment. The inventory was built combining data sources such as information from existing literature, LCA database such as ecoinvent, and experimental results provided by researchers. To reconcile divergences between these different sources, process design and modeling such as ASPEN is a useful digital tool, requiring input from multidisciplinary working group including chemical researchers, LCA experts, and process engineers.
Additionally, with an early-stage process design/modeling we identified bottlenecks in a (chemical) process, e.g. energy intensive steps or built-up of impurities or hazardous chemicals. From a process design, an initial cost estimation was made to initiate an early SSbD step 5 (economic) assessment. This estimation gave insights into what the expensive steps are going to be and where the major improvements could be made. The above-mentioned points are valuable input for R&D, as these provide guidance to which experiments/tests are needed, or where the focus for alternative solutions should lay.
It will be the final aim of BIORING to apply and adapt the SSbD EU Framework to biocoatings.
The Bioring is a Circular Bio-based Europe Joint Undertaking funded project (2023-2026, GA 101112379).

6.05.P-Tu458 Methods and Tools to Assess Exposure and Risk for Steps 2-3 of the SSbD Framework for Advanced Materials

Vicenc Pomar-Portillo[1]*, Alberto Katsumiti*[2]*, Isabel Rodriguez-Llopis*[3]*, Blanca Suarez Merino*[4]*, Andrea Brunelli*[5]*, Elena Badetti*[5]*, Elisa Giubilato*[5]*, Erik Laurini*[6]*, Carlos Fito*[7]*, Santiago Aparicio*[8]*, Janeck J Scott-Fordsmand*[9]*, Morgan Lofty*[10]*, Danail Hristozov*[11] *and Bernd Nowack*[1]*, (1)EMPA - Swiss Federal Laboratories for Materials Science and Technology, Switzerland, (2)GAIKER Technology Centre, Basque Research and Technology Alliance (BRTA), Spain, (3)GAIKER, Spain, (4)TEMASOL, Switzerland, (5)Ca Foscari University of Venice, Italy, (6)Universita degli studi di Trieste, Italy, (7)ITENE, Spain, (8)Universidad de Burgos, Spain, (9)Aarhus University, Denmark, (10)Institute of Occupational Medicine (IOM), United Kingdom, (11)Green Decisions, Italy*

The European Commission's Safe and Sustainable by Design (SSbD) framework represents a pivotal initiative to integrate safety, environmental sustainability, and societal benefits into the design of materials and chemicals. Advanced Materials (AdMa), including nanomaterials and multicomponent systems, present unique challenges to this framework due to their dynamic properties, life-cycle transformations, and diverse application scenarios. Steps 2 and 3 of the SSbD framework target the critical phases of production, processing, use, and disposal, requiring robust and adaptable tools to assess exposure and risks across these stages.

This study systematically reviewed 31 tools for exposure and risk assessment, categorizing them into three tiers based on complexity, data requirements, and usability. The review identified gaps in tool availability, with some tools outdated or inaccessible, and highlighted promising advancements from recent projects, although some are not yet widely available to the public. Additionally, challenges persist in addressing AdMa-specific behaviours, including aggregation, dissolution, and transformations throughout their life-cycle.

The findings underscore three critical challenges: persistent data gaps, the need for better integration of tools across life-cycle stages, and the limited accessibility of high-complexity tools for smaller enterprises. Overcoming these obstacles will require the development of adaptable methodologies, enhanced data-sharing practices, and cross-sector collaboration to make tools more user-friendly and broadly applicable. This study provides a comprehensive assessment of tool readiness and highlights actionable insights to support the effective implementation of SSbD principles for AdMa, paving the way for safer and more sustainable innovation.

Disclaimer/Disclosure: Acknowledgement - This work was supported by the European Union s HORIZON EUROPE research and innovation programme under Grant Agreement No. 101137324 (SUNRISE). CH participants in SUNRISE Project receive funding from the Swiss State Secretariat for Education, Research, and Innovation (SERI).

6.05.P-Tu459 Integrating Computational Models and Balancing SSbD Dimensions to Satisfy the Industry Needs for Responsible Innovation on Advanced Materials and Chemicals

*Martin Himly[1] and **Iseult Lynch**[2], (1)Paris Lodron University of Salzburg, Austria, (2)Centre for Environmental Research & Justice (CERJ), University of Birmingham, United Kingdom*

Safe-and-Sustainable-by-Design (SSbD) advanced materials and chemicals (AMC) are a central requirement for reaching the ambitious goal of making Europe the first digitally enabled circular, climate-neutral, and sustainable economy. Novel AMC need to provide the high functionality required for their advanced applications, whilst simultaneously exhibiting improved safety and sustainability performance considering the complete value chain and life cycle. To facilitate adoption by industry and, by doing so, foster the twin green and digital transition of Europe s economy, the PINK Project aims to produce innovative modelling software and integrated workflows for the development of AMCs, which are combined into an industry-ready open innovation platform, the PINK In Silico Hub. PINK takes a holistic by-Design approach targeting the primary goal to satisfy the needs of industry, as implementing SSbD presents the multi-objective optimization problem to balance the four requirement categories functionality, cost-efficiency, safety, and sustainability. PINK employs industry-driven developmental Case Studies establishing scenarios that operate at different development stages within the industrial AMC innovation pipeline: Scenario 1 at business opportunity stage where multiple candidates can be generated in silico and potentially later arising sustainability constraints are to be determined by predictive modelling in parallel to functional performance testing; Scenario 2 at innovation development stage defined by one lead structure identified and some information is available with in silico tool-based modifications going on and sustainability criteria being evaluated; Scenario 3 at later material design stages where more data for several dimensions becomes available. Computational models are assembled in the PINK Matrix that enable an automated SSbD guidance prioritized according to industry-relevant implementation profiles. Depending on case requirements and scenarios envisioned, PINK intends to address elements of all five steps of the SSbD Framework, employing selected in silico tools, continuously improving the confidence in the predictions over multiple design cycles by producing new knowledge on a constantly reduced set of better performing candidates for replacing substances of concern. Industry readiness shall be guaranteed by improving usability, practicability, user experience, data provenance, documentation, and security.

6.05.P-Tu460 Navigating through Safe-and-Sustainable-by-Design (SSbD): Scoping Analysis

Inmaculada Gomez[1], Elvira Villaro[2], Lya G. Soeteman-Hernandez[3], Irantzu Garmendia Aguirre[4], Mónica Martínez[2] and Ana Serrano[5], (1)Avanzare, Spain, (2)Avanzare Innovacion Tecnologica, Spain, (3)RIVM, Netherlands, (4)Joint Research Centre (JRC), Belgium, (5)ICP.CSIC, Spain

Safe-and-sustainable-by-design (SSbD) is an integral component of the European Chemicals Strategy for Sustainability (CSS) action plan which aims to reduce negative impacts on human health and the environment associated with chemicals, materials, products and services commercialized or introduced onto the EU market (EC 2020). This had led to a series of publications from the European Commission (EC) Joint Recent Centre (JRC) including: i) a review of safety and sustainability dimensions, aspects, methods, indicators and tools (Caldeira, Farcal et al. 2022); ii) the SSbD framework for the definition of criteria and evaluation procedure for chemicals (Caldeira, Farcal et al. 2022); iii) the application of SSbD framework to case studies (Caldeira, Garmendia Aguirre et al. 2023); and iv) the SSbD chemicals and materials methodological guidance (Abbate, Garmendia Aguirre et al. 2024). The aim of the SSbD framework is to support the design and development of safe and sustainable life cycles of chemicals and materials with research and innovation (R&I) activities. The recent published methodological guidance introduces a scoping analysis which supports the contextualization of the assessment phase of the SSbD framework in R&I activities (Abbate, Garmendia Aguirre et al. 2024). The Scoping Analysis builds on: i) the system definition, ii) the (re)design definition, iii) the definition of the system boundaries and iv) engagement with the actors along the life cycle. These three building blocks are necessary, but they can be implemented in a different order based on the industrial cases. Here a case study is presented on the application of the scoping analysis. Commercial flame retardants for polymers are currently the standard materials used in the automotive industry; however, they pose issues related to high persistence and allergenic potential. In this context, graphene oxide presents itself as a versatile material, as it can be functionalized with different additives of biological or natural origin to improve its properties and reduce the toxicity. SSbD strategies were generated for a graphene oxide functionalized with chitosan (N-acetylglucosamine), a benign biopolymer with flame retardant properties used as a substitute for halogenated flame-retardant products. This option does not use hazardous materials, reduces consumption of water in production process, reuses material lost during production and minimizes occupational exposure.

6.05.P-Tu461 Interoperability fir bridging SSbD Dimensions, Value Chains and Material Life Cycle Stages

*Thomas Exner[1], Joahim Dokler[2], Francesca Lonstad Bleken[3], Jesper Friis[3], Thomas Fj stad Hagelien[3], **Iseult Lynch**[4], Georgios V. Gkoutos[4], Haralambos Sarimveis[5], Penny Nymark[6], Francesco Mercuri[7], Antreas Afantitis[8], Steffi Friedrichs[9] and Martin Himly[10], (1)Seven Past Nine, Germany, (2)Seven Past Nine, Slovenia, (3)SINTEF Ocean, Norway, (4)University of Birmingham, United Kingdom, (5)National Technical University of Athens, Greece, (6)Karolinska Institutet, Sweden, (7)Consiglio Nazionale delle Ricerche, Italy, (8)NovaMechnics, Cyprus, (9)AcumenIST, Belgium, (10)Paris Lodron University Salzburg, Austria*

Industry is in need of advanced materials and chemicals to comply with the goals of the European Green Deal based on a twin green and digital transformation. These must provide the expected new or improved functionality and, at the same time, be both safe and sustainable, i.e. need to be developed following the Safe-and-Sustainable-by-Design (SSbD) paradigm.

Many projects including PINK and MACRAMÉ are developing new experimental and computational methods supporting the design of SSbD materials considering the complexity of the materials themselves as well as the new challenges resulting from the need to characterize the materials and products, they are used in, at the use and end-of-life stages of the material life cycle. Being able to apply all these tools in real-world scenarios and, in this way, supporting industry to adopt a SSbD mentality is not only a question of availability of tools. They also need to be interoperable, trustworthy, and future proof, i.e. tools from different providers have to work together, results must be understandable to allow informed decisions and today s tools need to be complemented or even replaced by new tools for improving accuracy and confidence.

We are currently designing and implementing major components for a technical and semantic Interoperability Framework. This is based, on the one hand, on microservices providing the data resource, model and software and, on the other hand, on data documentation and annotation on different levels based on clearly defined data models, combination and harmonization of chemical, material, biological and medical ontologies as well as ontologies to annotate (meta)data models. On top of this framework, multiple infrastructure components are built: (i) the Project Registries (e.g. MACRAMÉ, BIO-SUSHY and PINK), which index all available services and data, (ii) workflows combining different services, (iii) an integrated knowledge graphs construction in form of the PINK Knowledge Base (PINK KB) providing relationships between tools, and (iv) the components of a central PINKISH platform (decision support workflow, generative AI for proposing new materials and a chemical/material dashboard). The presentation will describe these new concepts, approaches and tools and how data and models will, as a consequence of more general adoption, become more independent so that they can be sustained even if the original databases or platforms (including PINKISH) are retired.

Disclaimer/Disclosure: This work was performed as part of the PINK and MACRAMÉ projects, which have received funding from the European Union s Horizon Europe Research and Innovation programme (Grant Agreement No. 101137809 and 101092686, respectively), the Swiss State Secretariat for Education, Research and Innovation (SERI) and Innovate UK.

6.05.P-Tu462 Bringing Safe-and-Sustainable-by-Design to the Public – Exploring Stakeholders' Concerns and Needs Towards Nanotechnologies

*Jan Hildebrand[1], **Stefanie Prenner**[2], Caitlin Ahern[3] and Beatriz Alfaro Serrano[3], (1)IZES gGmbH, Germany, (2)Brimatech Services GmbH, Austria, (3)BioNanoNet Forschungsgesellschaft mbH, Austria*

Nanomaterials are characterised by their great potential in research and industry, but at the same time are still relatively little known to the public. Even though many application areas of nanomaterials, including cosmetics, medicine and electronics, are advancing to provide a more Safe-and-Sustainable-by-Design (SSbD) approach, public perceptions towards nanotechnology are sceptical. Within this study, a multi-method approach was used in order to examine relevant factors on public and stakeholders perceptions. Firstly, a multi-level media analysis in Germany observed the societal discourse on nanomaterials, different actor groups and factors of public acceptance. This analysis included data from newspaper articles (N=272), semi-scientific magazine articles (N=99) and on the social media level user comments from thirteen YouTube videos on nanotechnology advancements. Following, expert interviews and a pedestrian survey in Germany (N=34) were conducted to prepare an expert workshop (N=20) to discuss the potential and challenges of public trust towards nanomaterials in sunscreens. In addition, a survey along stakeholders in nanotechnologies was conducted.

Findings from the media analysis showed that the reporting of technology development was predominantly descriptive and did not discuss the social implications for the public. There was an ambiguity concerning the health and ecological risks of nanomaterials in the articles, which portrays the scientific uncertainty of this technology. Furthermore, social media users were opinionated towards nanotechnology, ranging from sceptical views of potential misuse to hopeful and curious outlooks on the future of applications. There tends to be disappointment in not receiving the promised advancements in nanoscience, shaped by its intangible nature and existing associations of the technology. Thus, there is a need for continued efforts to enhance public engagement by increasing and diversifying the range of topics in news reports and creating outreach activities from social media channels to disseminate information. Based on the results and under the motto Bringing SSbD to the public , information and communication materials such as factsheets and a nano-quiz were developed and distributed, thereby gaining important experience in how people can be reached and addressed on this complex topic through science communication.

Disclaimer/Disclosure: The research leading to these results has received funding from the European Union s Horizon 2020 research and innovation programme under grant agreement No 953152.

6.06 Communication for Tomorrow: From Experimental Design Towards Societal Impact

6.06.T-01 Bridging Science and Law: Effective Communication in Water Reuse Projects

*Sophie Melchers[1] and **Jan Christof Specker**[2], (1)Utrecht University Centre for Water, Oceans and Sustainability Law, Utrecht University, Netherlands, (2)Institute for Biodiversity and Ecosystem Dynamics, University of Amsterdam, Netherlands*

Climate change and environmental researchers are united by a shared understanding of the urgency of the environmental problems our world is facing. However, what often separates them is a shared vocabulary and language. Depending on their academic background, each scholar will interpret and use concepts such as climate mitigation , ecosystem or water regulation according to the customs in their scientific discipline. Often falsely assuming others have the same understanding as them of these central concepts. These potential misconceptions can hinder to practically and effectively communicate research findings and propose solutions that ultimately lead to environmental and, therefore, societal benefits.

This work draws on insights gained from the interdisciplinary research project AquaConnect, which focuses on transitioning the Dutch water management system toward circularity, where water is reused instead of discharged. Workshops held throughout the project offered open communication and discussions to align the research questions towards stakeholders needs. These discussions highlighted the need for a harmonized vocabulary across disciplines in water reuse research, especially the science-law relationship. Differing interpretations of key phrase for water reuse between legal frameworks and scientific literature show that this can lead to legal grey areas. Such situations offer room for practitioners to adapt innovative solutions to environmental problems but simultaneously deter practitioners due to unclear regulatory boundaries.

This work emphasises the need to include legal scholars early on in interdisciplinary work which focuses on environmental problems that are influenced by regulatory frameworks. Using water reuse as a case example shows that at the intersection of human and environmental health, multiple legal as well as scientific perspectives must be recognised and defined to propose effective solutions. Therefore, addressing legal implications alongside scientific practises and stakeholder engagement, allows research projects to be shaped towards deliverables that can effectively benefit the environment and society.

6.06.T-02 What's in Our Water? Sailor's Scientific Strategies
Katie Reilly[1]*, Liam Hanna*[2]*, Ben Gilbert*[2]*, Caitlin Vinicombe*[2]*, David Tubbs*[1]*, Sam Dobson*[2]*, Tony Elgar*[2] *and Iseult Lynch*[1]*, (1)University of Birmingham, United Kingdom, (2)Marine Society and Sea Cadets, United Kingdom*
Societal interest in water quality has increased whilst water quality has been reported to decrease in the UK over recent years. The decline in water quality is often attributed to a combination of increased sewage overflows, changes of land use, plastic mismanagement and introduction of new chemicals and materials into circulation. Young people are also often reported to be one of the groups that are most impacted by eco-anxiety, which is a term that is used to describe the hopelessness and frustration often felt by people when they are faced with environmental issues.
Through this project, we worked with Sea Cadets UK, a charity working with young people aged 9-18 in the UK with a focus of maritime activities. The projects had a two-step approach to firstly; develop a practical workshop exploring data collection and advocacy and secondly; a sampling campaign to collect water quality data in environments that they use for boating. The aim of the project was to involve people in those environments with the experimental design and data collection for these sites, and to co-create a workshop to share this process and the results. Establishing the common ground of water quality assessment and the challenges with balancing different societal and environmental pressures for management plans also facilitated the further development of discussion on Advanced Materials risks and ecotoxicity methods used to assess these.
Testing included temperature, pH and conductivity, nitrates and phosphates and a secchi disk to test the turbidity. Sampling took place at 8 sites across the UK including a mix of coastal, freshwater, brackish, estuarine and Sites of Special Scientific Interest.. Partnership building was an important aspect in this project and the interdisciplinary expertise across the network was highlighted, spanning pedagogy, photography and social media which added value to the project and outputs that could not have been achieved by a dissemination model from the research team.
In parallel, a practical workshop (230 attendees) was designed with the Sea Cadets Learning and Development team to facilitate discussion on environmental advocacy, the need for robust data and evidence and how to engage with decision makers (i.e. policy) going forwards. The workshop also included analysis of microplastics in water samples, which lead to discussion on analytical method development for particles, the challenges and the ecotoxicity risks and methods for freshwaters.

Disclaimer/Disclosure: This project was funded by the Natural Environment Research Council (Engaged Environments 2024).

6.06.T-03 The Price of PFAS: How Access to PFAS Information Affects Willingness-to-Pay for Products Labelled as "PFAS Free" or "Contains PFAS"
Svea Horberg[1]*, Lara Heinrich*[2]*, Antoaneta Mileva*[2]*, Bastian Knobl*[2]*,* ***Sabine Pahl***[2]*, Mathew White*[2] *and Ellise Marissa Suffill*[2]*, (1)University of Hannover, Germany, (2)University of Vienna, Austria*
Consumers are already faced with products labelled as Per- and poly-fluoroalkyl (PFAS) free. Meanwhile, regulation of some PFAS means products containing PFAS could soon carry a warning label. Yet public knowledge of PFAS remains low in Europe. How do consumers perceive such labels, and how does knowledge about PFAS affect it? We tested how people perceive free-from vs. warning labels on shoes with and without having information on PFAS provided. Based on other work, we predicted that participants given information would have higher WTP for products labelled as PFAS free and lower WTP for products labelled as Contains PFAS , compared to those who did not receive information. We also measured how emotional affect influenced decision-making, as prior work has shown that consumers tend to make decisions which reduce negative feelings and promote positive ones. To test our hypotheses, 406 participants were shown shoes and were asked how much they would pay for the product, and about the emotions they felt when viewing the product. Participants first saw shoes with no labels (i.e., baseline), and then with PFAS free and Contains PFAS labels in randomized order. The PFAS free label featured a leaf motif alongside the text. The Contains PFAS label featured pictograms with a red hazard diamond and text denoting persistent , mobile and toxic properties. Half of participants rated the shoes having been given further information on PFAS, including examples of function, risks, benefits and regulation of PFAS. Analysis used linear-mixed effects models. Since 93 participants reported having some knowledge of PFAS, we also included prior PFAS knowledge as a predictor. The PFAS free label led to significantly greater WTP than did the Contains PFAS label. Positive affect led to higher WTP and vice-versa for negative affect. Being given PFAS information during the study increased WTP for the PFAS-free label,

as did having prior knowledge on PFAS. What is crucial is the role of both information about PFAS (whether known prior or provided during the study) and emotions in mediating labelling effects. Having more information increased willingness-to-pay to avoid products with PFAS. Affect was significantly tied to consumer intention, and positive emotions were a stronger predictor than negative ones. Such data can provide insights on effective communications with consumers, particularly by accounting for psychological factors affecting perception.

Disclaimer/Disclosure: This project has received funding from the European Union s Horizon 2020 research and innovation programme under Grant agreement No 101036756, project ZeroPM: Zero pollution of persistent, mobile substances.

6.06.T-04 Cosmetics Labelling and Ingredients: Disentangling False-Claims and Empowering Consumers

***L. Cristiana Gheorghe**, Jonathan D. Oldfield and Iseult Lynch, University of Birmingham, United Kingdom*

I find information for the general public (not research publications) very confusing and scary
As a reasonably informed consumer, and a PhD student exploring the regulatory landscape for chemicals and their applications in cosmetics and personal care products, the more I read the more confused I get! So how on earth can the general public know what is safe and what is not? What is a genuine claim of sustainably sourced, natural or cruelty-free versus a green-washing statement that hides a multitude of murky practice under mis-information? When do consumers genuinely need to be concerned that there are harmful chemicals in their cosmetics, versus understanding that a lack of data to confirm the absence of harm underpins the precautionary principle, versus some data showing harm but at concentrations far above those that a consumer would ever be exposed to and not via a relevant exposure route?
Adding to the public communication challenges is (1) the breadth of regulations / directives that converge in the cosmetics area; (2) the complexity of ingredients lists and lack of clarity regarding the role of each ingredient in the product and that only ingredients above 1 wt% need to be reported; (3) the lack of data to rule out harm being conflated as evidence of harm (even by experts and regulators); (4) the massive exposure of the population estimates indicate that a typical product contains anything from 15 50 ingredients, and the average adult uses 9-15 personal care products per day, resulting in adults placing around 515 individual chemicals on their skin daily via cosmetics; and (5) the fact that the beauty industry is rife with illegal imports that evade EU regulation and mis-use of toxins (Botox) and medical substances (Ozempic) which are being mis-used.
In this work, we tease out these questions, by assessing the regulatory and voluntary certification landscape for cosmetics, the available tools and resources for evaluating the chemicals in cosmetics products (voluntary reporting schemes, mobile phone apps that scan product labels and report on their overall safety profile and generate case studies to communicate the key issues and a decision tree for identification of safe, sustainable and green cosmetics. One case study considered is the question of whether naturally occurring is always safer (better) then synthetic via a comparison of natural versus synthetic mica as part of the transition to biodegradable glitters.

6.06.T-05 Getting Beyond the Bubble: Measuring Effectiveness of Outreach Activities for SSbD-Related EU Projects

***Caitlin Ahern**, Barbara Ebner, Beatriz Alfaro Serrano, Matiss Reinfelds and Johanna K. Scheper, BioNanoNet Forschungsgesellschaft mbH, Austria*

Effective scientific communication is vital for enhancing the societal impact of research, particularly in the context of projects funded by the European Commission s Horizon Europe program. Despite its importance, science communication often relies on a combination of intuition and empirical evidence, especially when addressing abstract or complex topics like Safe-and-Sustainable-by-Design (SSbD) principles. This raises critical questions about how to effectively engage audiences and foster the adoption of new scientific concepts.

This study explores strategies for maximizing the outreach and impact of science communication efforts, focusing on both digital platforms and in-person activities. The primary digital platform of interest is LinkedIn, a tool for engaging diverse professional audiences. Engagement metrics such as clicks, reactions, comments, and shares are analyzed from the LinkedIn profiles of ten EU-funded projects over a one-year period. Special attention is given to the types of posts that generate the highest levels of engagement and their reach beyond the immediate scientific community. Demographic analysis of the interacting audiences, combined with project´s website traffic data, provides insights into how different audiences discover and interact with scientific content.

In parallel, the effectiveness of in-person engagement activities, including workshops and public science events, is assessed to compare their reach and impact with online methods. These events, though less quantifiable, provide invaluable qualitative insights into stakeholder engagement.

The findings from this study aim to identify best practices for designing science communication strategies that effectively engage a broader audience. Practical recommendations will be provided to enhance communication and dissemination efforts, ultimately contributing to the successful adoption of complex scientific principles across various stakeholders and sectors.

Disclaimer/Disclosure: This work has received funding from the European Union s Horizon Europe research and innovation programme under grant agreement n°101092269 (NABIHEAL) and 101177608 (PLANETS).

6.06.P Communication for Tomorrow: From Experimental Design Towards Societal Impact

6.06.P-We499 Using Art to Expand Science Understanding in the Context of River Health

Amanda J Reichelt-Brushett*, Moya Costello and Grayson Cooke, Southern Cross University, Australia*

Over 30 years, and across 26 reports, the Richmond River, New South Wales, Australia, has consistently been classified as stressed and degraded with the catchment in worse ecological health than most estuaries in NSW . Drainage of wetlands in the 1800s and 1900s for flood mitigation and to support the development of agriculture has caused significant acid-sulphate soil problems. The depletion of riparian zones and nutrient runoff from agriculture and horticulture have caused excessive sedimentation and replacement of water tollerant vegetation with pasture grasses has led to flood related low oxygen levels and fish kills.
Similar degradation of rivers and wetlands across Australia is linked to long-term controversy and conflict between Indigenous peoples, environmental managers, irrigators and farmers, fishers, local councils, and State and Federal governments, with the core of the conflict being the work that rivers are asked to perform for very different groups of people. If Australia is to improve its relationship with and use of rivers then more holistic ways of understanding rivers, and strategies for representing and communicating this understanding, must be developed and brought together. Communicating the science of river health can be supported by using multi-disciplinary and innovative approaches.

During weekly water quality sampling for some 16 months a 250mL water sample was collected from each site for a dedicated artisit focus which evolved through practice led open-ended enquiry. Each 250mL sample was filtered and the filter paper retained. The tonal and highly varied visual samples provided the foundation of a large 11m exhibit that linked to water quality data and over 100 sediment samples collected from across the whole 22 446 km2 catchment. The exhibit was presented in the Northern Rivers Community Gallery as part of a larger exhibition Speaking with the River and included participatory workshops. The workshops engaged broader expertise to explore river health using our 5 senses and much more followed.

6.06.P-We500 Comic Strips as a Science Communication Tool

Serena George*, University of Wisconsin-Madison, United States*

My interaction with one perceptive 11-year-old sums up why laboratory animal research is so controversial. After I explained my toxicology research, which measures fish survival upon exposure to a chemical, she asked, So, you re becoming a veterinarian to save animals, but you re killing them? Researchers must constantly re-evaluate animal welfare principles and the ethics of sacrificing the few to save the many. At the same time, the relevance of highly controlled laboratory studies is aptly questioned by, for example, people whose livelihoods depend on production of these chemicals and the scientists who are trying to regulate them. I want to address this question I keep hearing: Why does laboratory research matter? Through a comic strip created with digitized ink and wash drawings, I tell the story of a laboratory fish who wonders what life is like beyond the walls of his tank. The character reflects on the sense of duty he feels toward keeping his wild friends safe through his participation in laboratory research; he considers the welfare benefits that life in the laboratory affords him; and he questions the real-world applications of studies conducted in such a controlled and simplified laboratory environment. When he is suddenly scooped up by a researcher and placed in an experiment in a real Wisconsin lake, he experiences the adventure of life in the wild and comes to appreciate his home in the laboratory. Our scaley, underwater friends tucked away in a laboratory can sometimes seem unrelatable. Through storytelling, art, and experimental data explained in plain language, this comic strip encourages the reader to view science from a new and hopefully more accessible perspective. The reader is invited to experience the excitement of scientific discovery and appreciate how laboratory research affects their everyday life. Other scientists may hopefully find inspiration on how to share their science story in a creative way to reach a broader audience.

6.06.P-We501 Knowledge, Attitudes, and Practices Towards Plastic Clean-up Technologies

*Giulia Leone[1], Marine Severin[2], Lisa Inès Devriese[3], **Ana I Catarino**[2], Kayleigh Wyles[4], Ine Pauwels[5], Peter L.M. Goethals[6] and Gert Everaert[3], (1)Ghent University, Research Group Aquatic Ecology; Flanders Marine Institute, (VLIZ); Research Institute for Nature and Forest (INBO); Research Foundation Flanders (FWO), Belgium, (2)Flanders Marine Institute (VLIZ), Belgium, (3)Ocean & human health, Flanders Marine Institute (VLIZ), Belgium, (4)University of Plymouth, United Kingdom, (5)Research Institute for Nature and Forest (INBO), Belgium, (6)Ghent University, Research Group Aquatic Ecology, Belgium*

In recent years, innovators have developed various technologies to facilitate the removal of mismanaged plastic, a growing global issue associated with poor management during the different stages of plastic s life cycle. These technologies may be a beneficial resource for engaging public awareness, providing plastic pollution data, and collecting and removing plastic from the environment. However, due to the novelty of these technologies, the relevant knowledge, attitudes, and practices regarding these technologies remain unclear. Using a mixed-method approach, the present study investigated the general public and stakeholders perceptions of plastic pollution, their knowledge and attitudes towards plastic clean-up technologies, and current practices. Cross-sectional survey data was collected from a representative sample of 948 adults living in Belgium, while qualitative interview data was gathered from seven stakeholders associated with areas of potential deployment of plastic clean-up technologies. Our preliminary descriptive results showed that the majority of participants considered plastic pollution to be a very big problem, and 46.9 % had heard of "plastic clean-up technologies" before, but only 6.6 % had ever seen one deployed in real life. Over 40% of the participants indicated having no knowledge at all about plastic clean-up technologies. Despite this, 84.2% agreed that plastic clean-up technologies can have a long-term positive impact on the environment in which they are deployed, and a percentage of 1.7 % disagreed. Further results will present associations between individual factors (sociodemographic, techno-optimism, value orientation) and the knowledge and attitudes toward plastic clean-up technologies. The interview data from the stakeholders will be analyzed by the time of the conference. In light of the fifth session of the Intergovernmental Negotiating Committee (INC-5) for an international and legally binding treaty to reduce plastic pollution, our preliminary results indicate that the public generally thinks that plastic clean-up technologies could lead to improvement in the area of deployment over time.

Disclaimer/Disclosure: From the 1st of November 2021 Giulia Leone is supported by the Research Foundation Flanders (FWO), as a PhD grant strategic basic research, application number 1S13522N/1S13524N.

6.06.P-We502 Safety and Sustainability of Innovative Materials – The Communication and Knowledge Base MANTRA

*Katja Nau[1], **Dana Kuhnel**[2], Christoph Steinbach[3], Harald F. Krug[4], Matthias Finkbeiner[5], Andreas Mattern[2], Lilla Nikl[3], Jessica Wilk[5] and Alexis Michael Bazzanella[3], (1)Institute for Automation and Applied Informatics (IAI), Karlsruhe Institute of Technology (KIT), Germany, (2) Helmholtz Centre for Environmental Research (UFZ), Germany, (3)Society for Chemical Engineering and Biotechnology (DECHEMA), Germany, (4)NanoCASE GmbH, Switzerland, (5)Technical University Berlin, FG Sustainable Engineering, Germany*

There is a great need for new and innovative materials in order to adequately meet the numerous societal challenges of our time. Some non-exhaustive examples of this are materials to secure the green energy transition (e.g. in production of green hydrogen) or materials replacing or reducing the use of rare elements (e.g. in industrial catalysts for processes that require little energy). Adaptation to climate change or securing clean water resources are other areas with a need for newly developed materials. However, not only the effectiveness and efficiency of the materials for the applications must be considered, but also the safety for humans and the environment as well as sustainability must be ensured.
The project MANTRA - Data on innovative materials for sustainability and transfer has the important task of supporting research projects that are developing promising materials and processes specifically for the use in membranes and catalysis. Support is provided in science communication, networking, public relations, development of sustainability indicators., advice on materials safety and industry and practice transfer.

In addition, MANTRA strives to present knowledge about health effects and sustainability of new materials and processes in the field of catalysis and membranes to the public via a website (https://materialneutral.info/en/), brochures and information flyers. Furthermore, status meetings, workshops and involvement in conferences facilitate the transfer of knowledge on material safety and sustainability between the relevant stakeholders, from material developers to consumers.
Specific challenges of the project include (1) data scarcity on materials safety for rare materials, (2) the almost unmanageably amount of data for common elements (e.g. TiO2), and (3) the allocation and selection of sustainability indicators from existing frameworks that are applicable to novel materials, addressing all three dimensions of sustainability. The project will develop strategies to overcome these challenges.
This poster is designed to present the MANTRA knowledge base, the scientists behind the project, and the goals and methods in communicating the safety and sustainability of innovative materials.

Disclaimer/Disclosure: The project is funded by the Federal Ministry of Education and Research (MANTRA, data on innovative materials for sustainability and transfer, FKZ 03XP0583).

6.06.P-We503 Building Networks for Outreach and Impact

*Maria Rydberg[1], Sophia Kristensson[2], **Yulia Liu**[1] and Anna Charlotte Wikstrom[1], (1)Swedish Life Cycle Center/Chalmers University of Technology, Sweden, (2)Chalmers University of Technology, Sweden*

Background Swedish Life Cycle Center
The Swedish Life Cycle Center, established in 1996 and hosted by Chalmers University of Technology, is a center of excellence that fosters collaboration among academia, research institutes, industry, and government agencies. The Center's vision is to accelerate sustainable transition through science-based life cycle action. The Center is a recognized player within the field with multidisciplinary methodology and collaboration between researchers, practitioners and decision makers. Operating as a neutral platform, the Center allows for mutual project development and co-creation among researchers, practitioners, and decision-makers. This neutrality is supported by a strong academia base, ensuring scientific credibility and transparency. A key part of our mission is to expand the understanding and application of the life cycle perspective. The Center is dedicated to developing communication efforts that make advancements in the field more accessible and actionable for a wider range of stakeholders.

Methods for Outreach
Network Building: Initially focused on large industrial companies and academia, the Center has expanded its network to include authorities and SMEs. Events and projects invite diverse participation, fostering influence and action. Networking remains a key outreach method.

Innovation Cluster: Funded by the Swedish Energy Agency and partners, projects aimed at wider audiences have both developed new digital communication channels and strengthened the network. Newsletters, LinkedIn, and YouTube channels have seen significant growth, with a tenfold increase on LinkedIn over five years.

Webinar Concept: In 2022, the Center launched "Life Cycle Talks," a webinar series presenting the research front to keep you up to date with the science and application of the life cycle perspective. This concept has built a platform for sharing, discussing, and exploring the latest research among researchers, government agencies, and industry while also driving new subscribers to the Swedish Life Cycle Center YouTube channel.

Summary
Grounded in its core values, network, and digital communication channels, the Center has significantly influenced decision-makers in industry and policy, promoting life cycle action. In the presentation we will share our methods and concepts which are transferable to any field requiring competence building, collaboration, and action-oriented decision-making

6.06.P-We504 Persistently Negative? Consumer Responses to Warning Labels Denoting Persistence, Mobility and Toxicity of Chemicals in Everyday Items

*Nina Vaupotic[1], Jules Schlosser[1], Sarah Hale[2], Sabine Pahl[1], Mathew White[1] and **Ellise Marissa Suffill**[1], (1)University of Vienna, Austria, (2)DVGW-Technologiezentrum Wasser, Germany*

Assessing risk of substances is an important part of managing chemicals, but risk assessment procedures may not be understood by the public who instead express risk perception. Emotional affect, concern and support for regulation are important for understanding risk perception. One way of communicating risk is via labels that indicate specific chemical characteristics, e.g., to consumers. These labels may carry warnings for persistence (P), mobility (M) and toxicity (T) in the case of some per- and poly-fluoroalkyls (PFAS). Yet studies so far tend to measure chemical risk perception only very broadly, e.g., by describing the public s chemophobia , a general negative disposition towards chemicals. More research is needed on how non-experts perceive specific characteristics on product labels, because consumer understanding and behaviour is one route to reducing use. This study is novel in testing risk perception of labels for combinations of P, M and T in everyday products. We predicted toxicity would produce the largest increase in risk perception, compared with persistence and mobility, due to greater non-expert familiarity with toxicity. We also examined whether differences in likely body contact with the product would increase risk perception based on prior work. 321 participants saw one of two products at baseline (no warnings) and rated them for affect, concern about using the product, and support for regulation of chemicals in the product. Participants then saw and rated the same kind of product another seven times with warning labels showing different combinations of characteristics in randomized order. Results were analysed with linear-mixed effects models. While we confirmed toxicity had the largest effects of any single characteristic (i.e., more negative affect, increased concern & support for regulation), persistence and mobility also showed these patterns over baseline (albeit to a lesser extent). Products with all three chemical characteristics (i.e., PMT) were seen as the riskiest. Greater likeliness of body contact increased negative affect. Despite differences in risk assessment vs. perception, results suggest that non-experts are somewhat sensitive to risks posed by PM substances (not only toxicity), and in general highly support chemical regulation of consumer products. We argue such data can inform better communication about chemicals, improve understanding of warning labels and bolster consumer support in reducing PFAS use.

Disclaimer/Disclosure: This project has received funding from the European Union s Horizon 2020 research and innovation programme under Grant agreement No 101036756,
project ZeroPM: Zero pollution of persistent, mobile substances.

6.06.P-We505 Estuarine & Marine Ecological Risk Assessment Research Immersion Model Improves Science Literacy and Student Engagement in Local and International Environmental Issues

***Maysoon Lehmeidi*[1]*, Kristie Evenson*[2]*, Chris Stransky*[3]*, Damian Shea*[4]*, Liisa Bozinovic*[5]*, Chris Witte*[5]*, Karen Najera Ruiz*[5] *and Goran Bozinovic*[5]*, (1)University of California San Diego, Division of Extended Studies, United States, (2)Pharos International Institute for Science, Arts and Culture, Croatia, (3)GEI Consultants, United States, (4)Statera Environmental, Inc., United States, (5)Boz Life Science Research and Teaching Institute, United States*

The Tijuana River Estuary (TRE), the largest coastal wetland in Southern California has been a source of contention between the United States and Mexico for decades due to transboundary pollution. The Boz Life Science Research and Teaching Institute and University of California Division of Extended Studies piloted research immersion programs for pre-college students to conduct environmental health assessments. Sediment and water samples from four sites during dry and wet seasons were used in sea urchin embryotoxicity testing; the abundance of sediment-bound chemical pollutants was investigated by qualitative non-target analysis and quantitative targeted analysis using GCMS and LC MS/MS. Novel composite integrative samplers (CIPS) were deployed in water to quantify polar and non-polar chemicals, providing time-weighted-average concentrations. 16S rRNA sequencing was used to explore correlations between microbial diversity and chemical contamination. Pre-college students interpreted scientific literature, generated hypotheses, designed and executed experiments, applied biostatistics and bioinformatics to analyze data and infer biological relevance. The program concluded with a student presentation during a symposium attended by scientists, educators, government officials, and industry leaders. A similar method was applied to promote the engagement of high school students at the Croatian island of Hvar: to assess the potential adverse anthropogenic effects on sea water quality, a comprehensive ecological risk assessment was initiated. CIPS were deployed for ten days at 16 sites covering both low and high levels of human activities along the 65 km island, which is one of the most popular summer tourist destinations in the world and a UNESCO heritage site. Students also collected native mussels (Mutilus galloprovincialis) and sea urchin (Arbacia lixula) at these sites to correlate body burdens with CIPS chemistry profiles; animal tissues will be used for metagenomic analysis. Animal tissues will also be used for gene expression profiling to identify biomarkers of exposure to complex industrial chemical mixtures. Besides identifying public health hazards and promoting legislative action, the goal for both programs is to serve as foundations for a long-term international research collaborative and students exchange program focused on pressing environmental issues while cultivating future STEM community leaders and stewards of responsible environmental policies.

Disclaimer/Disclosure: The Tijuana River Estuary Research Immersion Program is supported by the University of California San Diego, Division of Extended Studies in partnership with The Inamori Foundation and Girard Foundation as part of the development and implementation of Futures Life Sciences student research immersion program at the Boz Life Science Research and Teaching Institute.

The Island of Hvar Ecological Research Assessment Pilot Project has been generously supported by the Matko and Vera Mili?i? Foundation, Mayor s offices from Hvar and Stari Grad, and the Island of Hvar Nautical Center. Funding for research is provided by Statera, Inc (North Carolina, U.S.), and Boz Life Science Institute (San Diego, U.S.).

6.06.P-We506 Mainstreaming the Fish Invitrome for Animal-free Environmental Risk Assessment: An Expert Interview Campaign

Marion Revel[1], *Jessica Bertoli*[1], *Mihai-Ovidiu Degeratu*[1], *Ksenia J Groh*[1], *Jarno Hoekman*[2], *Colette vom Berg*[1], *Bernhard Truffer*[1] *and Kristin Schirmer*[1], *(1)Eawag, Swiss Federal Institute of Aquatic Science and Technology, Switzerland, (2)Copernicus Institute of Sustainable Development, Utrecht University, Netherlands*

Large numbers of fish are being used each year for chemical risk assessment, raising ethical, practical, and economic concerns. Given the need to reduce animal testing, new approach methods (NAMs) using fish cell lines have been developed over the past decades. To strengthen confidence in the predictions provided by these fish cell line-based assays, we aim to develop a modular framework, the fish invitrome, capable of predicting chemical toxicity without the use of animals. This framework comprises several modules to assess different effects, such as mortality (using the RTgill-W1 cell line assay (OECD TG 249)), chemical bioaccumulation/biotransformation, inhibition of growth, neurotoxicity, and reproductive toxicity.

Establishing a new method and achieving the status of a validated method, such as an OECD test guideline (TG), takes at least a decade, similar to developing a new pharmaceutical. Still, even after the adoption as an OECD TG 249 in 2021, the global status of implementation of the RTgill-W1 cell line assay in risk assessment practices remains unclear. Therefore, to accelerate the uptake of that assay and of the expanded fish invitrome framework, our objective is to identify different pathways of application in specific ecotoxicological application contexts, rather than focusing solely on immediate regulatory acceptance. This requires a deeper understanding of current ecotoxicology risk assessment practices by different regulatory agencies, industries, NGOs, and researchers. As a first step, therefore, we performed an expert interview campaign with a dozen representatives from different industrial sectors to understand (1) what kind of risk assessment is being done, (2) how fish cell line tests could fulfil their ecotoxicology assessment needs, and (3) how the field of ecotoxicological assessment might develop over the coming years.

This interview campaign highlighted different challenges and barriers across the industrial sectors in the implementation of these NAMs. These results will allow us to develop a stepwise approach for mainstreaming the fish invitrome framework, in order to make it widely understood, trusted, and used in various ecotoxicological applications. This socio-technical approach promises to promote a broader use of the fish invitrome framework in practical applications while gradually overcoming institutional, cultural, and technical barriers.

6.06.P-We507 Dear Dearbhla: Nature's Agony Aunt

Katie Reilly *and Iseult Lynch, University of Birmingham, United Kingdom*

Dear Deabhla much like an agony aunt gives life advice, we can turn to indicator species, and model organisms for environmental advice. What will happen if temperatures rise in freshwater ponds? How might microplastics change algae populations in rivers? Daphnia, or waterfleas, have been recognised as sentient species in freshwater environments for a long time, and are widely used as a proxy, or model, species to understand how environmental challenges might affect ecosystems. Dearbhla, the Daphnia, takes a novel approach to science communication by taking the model organism, bringing them out of the laboratory and anthropomorphising them, quite literally in the form of a Daphnia costume. This allows us to highlight the scientific important and development of Daphnia, or water fleas, as an amazing model organism that are used globally as indicators of good environmental health. They have been historically used for freshwater toxicity testing of chemicals, and more recently nanomaterials and microplastics. For context, Daphnia are transparent organism and are keystone species in freshwater environments because they link the primary producers (algae) with higher trophic levels in the food web (fish and other insects etc). Under healthy/normal conditions they will reproduce genetically identical daughter offspring and will only produce male Daphnia when stressed, which is reflected in Dearbhla having a removable brood pouch. A range of methods that have been developed to monitor environmental health such as the use of fluorescent particles and dyes, video capture methods to explore how their movement changes and a range of molecular methods to determine their cellular response to pollutants. Dearbhla can bring all of this research to the public in an engaging and visual way and supports some of the hands- on activities. Some of these events have included science festivals and open day events where Dearbhla has attended, and acted as an agony aunt to answer the public questions on environments issues. We have found this to be really engaging due to the visual nature, the opportunity to take photos and the novel element- many people haven t seen a Daphnia so having a human sized one draws some interest! Dearbhla creates a novel lens through which to engage different audiences with new environmental science and ecotoxicological approaches, which allowing two-way communication between model organisms and the public.

6.07 Environmental Risk Assessment Under Biocides and Other EU Legislations

6.07.T-01 Take EU Biocides Legislation to the Next Level

***Stefanie Wieck**, Corinna Burkart and Sascha Setzer, German Environment Agency (UBA), Germany*

Biocides are chemicals or microorganisms used to control harmful organisms to protect human or animal health or materials, but their use can pose environmental risks. The European Union s Biocidal Products Regulation (EU) No 528/2012 (BPR) governs approval and authorisation, requiring environmental risk assessments (ERA) for both active substances and products in a two-step process. It involves hazard-based and risk-based assessments.

Since entry-into-force of the BPR in 2013, there have been many lessons learned from the implementation of the regulation. Additionally, the One Substance One Assessment (OSOA) approach was introduced by EU in 2020. Based on the experiences made, research projects and the new OSOA approach, the authors compiled recommendations to make BPR fit for the future. This contribution aims to provide recommendations to enhance environmental protection and accelerate ERA procedures.

Enhancing Environmental Protection: Gaps in BPR might lead to preventable environmental risks, particularly in the areas of endocrine disruption, simplified authorisation processes, and the sustainable use of biocidal products. Proposals include strengthening the requirements for simplified authorisations, and incorporating principles for sustainable use during the application phase. These changes could help minimize environmental harm, improve public communication, and support sustainable management of harmful organisms.

Accelerating Risk Assessment Processes: Delays in the approval of active substances and product authorisations can be driven by the complexity of ERA and ambiguous regulatory language. The authors suggest pragmatic approaches to streamline the assessment of disinfection by-products and address issues arising from substances regulated under multiple chemical legislations.

BPR has been a milestone towards a better protection of the environment. However, in times of Zero Pollution Ambition, OSOA and more than a decade of experiences with the legislation, it is time to take it to the next level.

6.07.T-02 A City is Not a Field - Progress in the Groundwater Assessment for Urban Biocide Emissions

***Maura Schwander**[1], Christiane Meier[1], Maren Ahting[1], Michael Patrick[2], Michael Burkhardt[2], Felicia Linke[3], Jens Lange[3], Dimitrios Alexander Skodras[4], Judith Klein[4] and Michael Klein[4], (1)German Environment Agency (UBA), Germany, (2)Institute for Environment and Process Engineering (UMTEC), OST- Eastern Switzerland University of Applied Sciences, Switzerland, (3) University of Freiburg, Germany, (4)Fraunhofer Institute for Molecular Biology and Applied Ecology (IME), Germany*

The environmental risk of emissions of biocides from construction materials in urban areas is well documented. Precipitation can lead to significant entries of biocides and their transformation products into surface waters and groundwater aquifers. Emission scenarios are established for the modelling of biocide releases to surface water in cities. However, a model taking into account the specific conditions in urban soils and entry pathways to groundwater is currently not harmonised for the regulation of biocidal products.

We developed realistic worst-case scenarios in order to achieve a more realistic assessment of biocide emissions from building façades into urban groundwater. Thereby, urban soil properties and depths to groundwater were thoroughly analysed and considered. Representative entry pathways in urban areas namely vegetated soils, permeable pavements and infiltration systems - were integrated as well as a refined building geometry and a realistic building density for central Europe. National technical guidelines on the design of swales and permeable pavements in Europe were analysed to identify further key parameters. These input data were integrated into the dynamic leaching model COMLEAM (COnstruction Material LEAching Model) and the soil transport models PEARL and PELMO. By including all three

emission pathways to the model chain, biocidal emissions to urban groundwater could more realistically be described.
Based on the gained knowledge we elaborated a guideline for architects, engineers, and municipalities. Hereby, sustainable construction practices shall be enhanced to reduce biocide emissions in urban areas. This can lead to better groundwater protection and more sustainable rainwater management in modern blue-green infrastructure strategies.
In the next step, the existing Emission Scenario Documents (ESD) for biocides need to be adapted for an adequate consideration of the outcome in regulatory processes. Recommendations for a more realistic exposure assessment are presented, specifically for the characterisation of building geometries and the inclusion of the diverse urban emission pathways.

6.07.T-03 Comparison of Environmental Exposure Assessment Strategies in Different EU Legislation

Heike Schimmelpfennig, *Brill Regulatory Services GmbH, Germany*
Introduction: Before chemical substances and/or products are placed on the EU market, their risk to human health and to the environment has to be assessed according to the intended use. Depending on their use, substances and/or products are regulated under different EU legislation. In the case of dual use (e.g. disinfectants used as medical device and biocide), the same substances and/or products are assessed under different legislation.
This abstract compares and evaluates the different and common ways of performing an environmental exposure assessment in different legislation. The focus is on similarities and differences and it is assessed whether they can be harmonised.

Materials and Methods: The first step is to identify legal areas where the same substance is used under different EU directives or regulations (e.g. insecticides used in stables as biocide or veterinary products, or surface disinfectants used in healthcare as biocides or medical devices).
The exposure assessment strategy between this EU legislation is then compared on the basis of different parameters.

Results and Discussion: The exposure assessment strategies and the depth of the assessment differ between the EU legislation assessed. The extent of the differences as well as the differences in the assessment strategies as such are presented in detail. The reasons for the differences are also evaluated.

Conclusions: With regard to the one substance one assessment strategy, the exposure assessments of different chemicals assessed under different EU legislation could be further harmonised. Several suggestions are made on how such harmonisation could be achieved.

6.07.T-04 Towards a Holistic Approach in Chemical Exposure Assessment: The ExpoAdvance Roadmap

Lara Lamon[1], *Alicia Paini*[1], *James Doyle*[2], *Ruth Moeller*[3], *Susana Viegas*[4], *Francesco Cubadda*[5], *Peter Hoet*[6], *An van Nieuwenhuyse*[3], *Henriqueta Louro*[7], *Maria Dusinska*[8], *Karen S. Galea*[9], *Rebecca Canham*[9], *Carla Martins*[4], *Ana Gama*[4], *Vania Teofilo*[4], *Maria Joao Silva*[7], *Celia Ventura*[7], *Paula Alvito*[7], *Naouale El Yamani*[8], *Manosij Ghosh*[6], *Duca Radu*[3], *Marco Siccardi*[1], *Elise Runden-Pran*[8], *Cronan McNamara*[2] *and Paul Price*[10], *(1)ESQlabs, Germany, (2)Creme Global, Ireland, (3)LNS, Luxembourg, (4)ENSP, Portugal, (5)ISS, Italy, (6)KU Leuven, Belgium, (7)INSA, Portugal, (8)NILU, Norway, (9)IOM, United Kingdom, (10)Risk Sciences, Canada*
Historically, chemical risk assessments have primarily focused on a chemical-by-chemical approach, evaluating risks associated with exposures from individual sources. However, individuals are exposed to chemicals from multiple sources, as each chemical can exist in various environmental media, foods, and consumer products. This submission focuses on ExpoAdvance, the EFSA roadmap on aggregated exposure, as an example of a holistic approach in the field of chemical exposure assessment. AE is defined as the combined exposure to a chemical from all sources through different routes. Estimating AE is crucial because it is the total dose that determines the overall toxicological effects of a chemical, rather than isolated doses from single sources. AE can be assessed using exposure models or the combination of human biomonitoring (HBM) data and physiologically based kinetic (PBK) models, and needs to be considered in the context of cumulative exposure. The EU Chemical Strategy for Sustainability s proposal for a one substance-one assessment approach underscores the importance of AE assessments across all chemicals as a key component of risk management. EFSA s goal for 2030 is to develop the capability, in collaboration with partners, to efficiently assess AE for chemicals, including contributions from specific sources of exposure in affected populations.

To meet the criteria of building a holistic approach and ensure consistency under different regulatory approaches, the ExpoAdvance roadmap was developed by performing engagement and data collection activities. From this data, we synthesized an initial tiered framework to guide AE assessments that align with EFSA s goals. We identified data gaps by pinpointing where existing AE assessment capabilities fell short of the framework, as well as challenges and barriers to bridging these gaps. These insights informed the development of research Working Areas (WAs) and the subsequent definition of eight project proposals that would allow EFSA and the regulatory ecosystem to embed AE in chemical risk assessment workflows. This contribution highlights two key findings from the roadmap: the proposed framework for AE assessment and the project proposals designed to operationalise it. Emphasis is placed on activities relevant to cumulative exposure and the promotion of holistic approaches in chemical risk assessment.

Disclaimer/Disclosure: The authors acknowledge the European Food Safety Authority (EFSA) and other EU and US stakeholders for their valuable support and guidance in shaping the ExpoAdvance roadmap.

6.07.P-Tu463 Comparing Environmental Risk Assessment Frameworks Under Different EU Legislations

*Alessio Ippolito and **Franco Ferilli**, European Food Safety Authority (EFSA), Italy*

This poster investigates the status of regulatory frameworks for the environmental risk assessment of chemicals. The EU represents an interesting case in terms of regulatory system for the environmental risk assessment of chemicals, since many different regulations co-exist.

Most regulations entailing risk assessment of chemicals aim to authorise (or re-authorise) the possibility to produce, sell, and use chemical substances or products containing multiple chemicals along with potential limitations to any of these activities. As such, these regulations are single chemical/product-oriented, and their domain of applicability is dictated by the specific use of the chemical/product. This poster will provide an overview for industrial chemicals, plant protection products, biocides, feed additives, pharmaceuticals for human and for veterinary use. Since the aim of these regulations involves pre-market authorisations, the methodologies used for the risk assessment within these frameworks mainly adopt a prospective approach, where monitoring plays a limited role.

On the contrary, media-specific regulations (such as the Water Framework Directive) rely heavily on a retrospective approach, as their scope is not to grant specific market authorisations but rather to ensure a certain quality standard of the receiving environment.

Quite interestingly, it is not uncommon for the same substance to be assessed under different regulations, depending on its use. For example, several chemicals are used either as PPPs and as biocides, and they are often also regulated as potentially impacting on the water quality.

Several frameworks are analysed in this poster from different perspectives, i.e. in terms of their overarching purpose to the adopted problem formulation (i.e., objects of protection, protection goals, spatiotemporal scales) and the hierarchical structure of the different risk assessment methodologies.

6.07.P-Tu464 Mapping Chemicals Across EU's Legal Frameworks Towards a 'One Substance, One Assessment' Approach

*Marlene Ågerstrand, **Mathilda Andreassen** and Christina Ruden, Stockholm University, Sweden*

EU chemicals legislation governs a wide range of chemicals, from those found in everyday items such as healthcare products and food packaging to pesticides, medicines, and waste treatments. Chemicals entering the EU market are typically registered and assessed under applicable laws for hazards and risk management. However, a single substance may have multiple uses and may be assessed under more than one framework, potentially leading to different assessment outcomes. To address these challenges, the European Commission introduced the "one substance, one assessment" approach as part of the Chemical Strategy for Sustainability (CSS). In this study, we mapped substances subject to assessment under multiple legal frameworks to evaluate the scope of the issue and identify challenges to implementation of the one substance, one assessment . Our findings showed that almost one-tenth of the substances identified were listed under more than one framework, highlighting the need for coordination of hazard and exposure assessment across frameworks. One important challenge identified was the notable lack of coherent chemical identifiers available to accurately identify substances across the frameworks, which will complicate efforts to align assessments and re-use and sharing of data. Additionally, we identified the presence of phthalates, bisphenols and PFAS in EU frameworks to illustrate how a group-based approach to chemical assessment could be applied across legal frameworks. As expected, a group-based approach spanned more frameworks compared to the single-substance approach, emphasising the need for coordination and communication across frameworks. Surprisingly, we also found that most of the phthalates, bisphenols and PFAS were not listed in the investigated frameworks while still notified in articles on the EU market according to ECHA´s SCIP database.

6.07.P-Tu468 Combined Sewer Overflows - A Neglected Source of Biocide Emissions?!

***Christiane Meier** and Korinna Ziegler, German Environment Agency (UBA), Dessau-Rosslau, Germany*

The sewage system acts as a reservoir for micropollutants, including biocides used as for example disinfectants, insecticides, and preservatives. These enter the sewage system via domestic wastewater or rainwater. During heavy rainfall, treatment plants often reach their capacity and discharge excess wastewater through combined sewer overflows (CSOs) into storage basins or directly into water bodies. This could lead to increased risk for the aquatic ecosystem in urban areas.

In recent years, the German Environment Agency (UBA) has conducted research on biocides in wastewater treatment plant effluents, including CSO discharges. Findings show that even with tertiary treatment, not all biocides are eliminated, allowing their release into water bodies. CSOs, lacking purification steps, discharge biocides directly.

Above all, substances used as material preservatives such as terbutryn, diuron, isoproturon, and isothiazolinones were detected in effluents. Imidacloprid and permethrin, found additionally in CSO samples, are particularly a cause of concern due to their high toxicity to aquatic life at low concentrations.

Climate change projections indicate more frequent, intense precipitation, increasing the relevance of CSO pathways in urban areas. Current environmental risk assessments for biocides exclude CSO inputs, considered negligible due to assumed rare occurrence. However, UBA findings and CSO occurrence data show that this pathway should be included in risk assessment of some biocides to better protect aquatic ecosystems.

6.07.P Environmental Risk Assessment Under Biocides and Other EU Legislations

6.07.P-Tu463 Comparing Environmental Risk Assessment Frameworks Under Different EU Legislations

*Alessio Ippolito and **Franco Ferilli**, European Food Safety Authority (EFSA), Italy*

This poster investigates the status of regulatory frameworks for the environmental risk assessment of chemicals. The EU represents an interesting case in terms of regulatory system for the environmental risk assessment of chemicals, since many different regulations co-exist.

Surprisingly, we also found that most of the phthalates, bisphenols and PFAS were not listed in the investigated frameworks while still notified in articles on the EU market according to ECHA´s SCIP database.

6.07.P-Tu465 Advancing the Environmental Risk Assessment of Pesticides to Better Protect Biodiversity Under PARC

Johan Axelman[1]*, Annette Aldrich*[2]*, Yann Devos*[3]*, Sabine Duquesne*[4]*, Vanessa Mazerolles*[5]*, Natasha Molgaard*[6]*, James Henty Williams*[6]*, Gustaf Bostrom*[7]*, Matthias Liess*[8]*, Ralf Bernhard Schaefer*[9] *and Jose V. Tarazona*[10]*, (1)Swedish Chemicals Agency (KemI), Sweden, (2)Federal Office for the Environment (FOEN), Switzerland, (3)European Food Safety Authority (EFSA), Italy, (4)German Environment Agency (UBA), Germany, (5)French Agency for Food, Environmental and Occupational Health and Safety (ANSES), France, (6)Aarhus University, Denmark, (7)Swedish University of Agricultural Sciences (SLU), Sweden, (8)Helmholtz Center for Environmental Research (UFZ), Germany, (9)Research Center One Health Ruhr, University Duisburg-Essen, Germany, (10)Instituto de Salud Carlos III (ISCIII), Spain*

Within the EU Partnership for the Assessment of Risks from Chemicals (PARC), the Activity 6.4.4 Risk assessment to support and promote efficient overall protection of biodiversity explores new lines of research to advance the environmental risk assessment (ERA) of chemicals within and beyond their current regulatory ERA frameworks (with an initial focus on chemical pesticides). The ambition is to foster the development and implementation of systems-based approaches for ERA that address regulatory needs.

The interconnected lines of research aim at: (1) the clarification of regulatory needs to ensure regulatory relevance and uptake of outcomes and bridge the research policy gap; (2) the updating and modernising of ERA approaches to ensure fitness for purpose; (3) the benchmarking of ERA against reality to simplify and speed up the ERA process and increase predictability; (4) the increase of ecological realism of ERA to deliver more realistc, context-dependent ERA predictions and risk mitigation/sustainable use measures and (5) the application of a systems-based approach for better connecting stakeholders and integrating data, knowledge and expertise within and across regulatory frameworks.

PARC 6.4.4 plays an unique role to advance the ERA framework for PPPs towards a systems-based approach in the EU, as it explores scientific avenues (including case studies) to simplify and speed up ERA methodologies, increase ERA s ecological realism, improve ERA s agility and ease the transition towards a systems-based approach to PPP ERA.

Issues with the PPP ERA identified in previous regulatory research projects (i.e., PERA, ZAPID) were acknowledged and confirmed by risk assessors engaged in PARC 6.4.4 through an online survey and workshops. We will present preliminary results of insights and feedback gain from risk assessors as part of the survey, and subsequent workshop exchanges. In addition, synergies with other EU projects that aim to advance the ERA of chemicals will be presented, and means to strengthen the collaboration among these projects, as well as stakeholders within and across regulatory frameworks will be explored.

By connecting relevant projects and stakeholders within and outside PARC, PARC 6.4.4 seeks to engage towards the establishment and implementation of a partnership on Next-Generation ERA (NG ERA) of chemicals.

6.07.P-Tu466 What Will be ECHA’s Role in Protecting Environmental Waters in the EU?

Pia Talja *and Chrystele Tissier, European Chemicals Agency (ECHA), Finland*

The European Chemicals Agency (ECHA) is set to embark on a new mandate to work on the water protection directives, including the Water Framework Directive (WFD), Environmental Quality Standards Directive (EQSD), and Groundwater Directive (GWD), as proposed by the European Commission in the revision of those directives under discussion. ECHA will be supporting the Commission in, for example, identifying priority substances and proposing environmental quality standards (EQS), establishing groundwater pollutant lists and quality thresholds, and identifying substances for watchlists for both surface water and groundwater.

In preparation for these new responsibilities, ECHA has started to familiarise itself with the future tasks by understanding better the scope of these tasks and how they have been managed historically. This includes analysing new requirements from the directives, such as the mandatory groundwater watchlist, identifying key stakeholders, and observing the work of the Commission s working groups. Regular exchanges with the Commission, the European Environment Agency (EEA), and the Joint Research Centre (JRC) have been crucial.

ECHA faces several key challenges in this transition. The long history of water protection work being handed over requires the acquisition of new expertise and the establishment of a suitable working relationship with existing Commission working groups. Defining ECHA s role and potentially introducing some changes to past practices will be needed. Additionally, both the Risk Assessment Committee (RAC) and the Socio-Economic Analysis Committee (SEAC) will be involved in this work and ECHA needs to figure out how to best use the committees and their expertise.

However, there are significant opportunities as well. ECHA s in-house expertise is extensive, and there is potential to create better synergies between water protection efforts and existing tasks. For instance, the water protection work is expected to provide additional information that could inform further regulatory actions, such as substance restriction. Streamlining tasks for surface and groundwater pollutants where relevant and integrating various chemical-related legislations under one roof, will help ensure a more holistic approach. This aligns with the broader goal of the One Substance, One Assessment legislation, promoting a comprehensive and unified regulatory framework for managing chemical pollution.

6.07.P-Tu468 Combined Sewer Overflows - A Neglected Source of Biocide Emissions?!

Christiane Meier *and Korinna Ziegler, German Environment Agency (UBA), Germany*

The sewage system acts as a reservoir for micropollutants, including biocides used as for example disinfectants, insecticides, and preservatives. These enter the sewage system via domestic wastewater or rainwater. During heavy rainfall, treatment plants often reach their capacity and discharge excess wastewater through combined sewer overflows (CSOs) into storage basins or directly into water bodies. This could lead to increased risk for the aquatic ecosystem in urban areas.

In recent years, the German Environment Agency (UBA) has conducted research on biocides in wastewater treatment plant effluents, including CSO discharges. Findings show that even with tertiary treatment, not all biocides are eliminated, allowing their release into water bodies. CSOs, lacking purification steps, discharge biocides directly.

Above all, substances used as material preservatives such as terbutryn, diuron, isoproturon, and isothiazolinones were detected in effluents. Imidacloprid and permethrin, found additionally in CSO samples, are particularly a cause of concern due to their high toxicity to aquatic life at low concentrations.

Climate change projections indicate more frequent, intense precipitation, increasing the relevance of CSO pathways in urban areas. Current environmental risk assessments for biocides exclude CSO inputs, considered negligible due to assumed rare occurrence. However, UBA findings and CSO occurrence data show that this pathway should be included in risk assessment of some biocides to better protect aquatic ecosystems.

6.07.P-Tu469 The Environmental Impact of AAV Gene Therapy vectors

Tobias Fleischmann*, Pfizer, Germany*

Background: Adeno-associated viruses (AAVs) have become the predominant vectors for in vivo gene therapy (GT). Despite their widespread use, the environmental risks associated with recombinant AAV (rAAV), particularly during the shedding phase, remain underexplored. This pair of studies aims 1) to address the biocontainment and hygiene requirements for handling secreta/excreta of GT patients and 2) to assess the environmental fate of shed rAAV particles.

Methods: Feces and urine samples from non-human primates treated with an AAV9-based GT vector (2E13 vector genomes per kilogram body weight) were analyzed for vector presence and cell-binding capacity. Additionally, the stability of four rAAV vectors (based on wildtype AAV serotypes 2, 3, 6, 9) was evaluated in activated sludge to simulate wastewater treatment facility (WWTF) conditions.

Results: Both feces and urine samples contained vector particles capable of binding to cells in a cell culture system. However, these shed particles exhibited a 2-3 orders of magnitude lower affinity to cells compared to novel control rAAV vector. In the environmental fate study, detectable virions in activated sludge decreased rapidly within hours, reaching the lower limit of quantitation by day 7. Under abiotic conditions, the half-life of rAAV virions was approximately 7 days.

Conclusions: The lower binding capacity of shed vector particles suggests that current stringent biocontainment and hygiene measures for GT patients could be relaxed. The rapid degradation of rAAV particles in WWTFs indicates that they do not pose an environmental threat. These findings support a more relaxed, risk-based regulatory approach for medicinal GMOs, potentially simplifying the regulatory review process and encouraging a science- instead of fear-based approach to the safety protocols for gene therapy applications, enabling faster access to GT to more patients.

Disclaimer/Disclosure: Both studies were funded by Pfizer Inc.

6.07.P-Tu470 Aerial Application of Plant Protection Products with Drones in Germany

Bianca Kuhne *and Jonas Schartner, Federal Office of Consumer Protection and Food Safety, Unit Environment, Germany*

In 2021 aerial applications of plant protection products with drones were approved in Germany for the first time.
According to the sustainable use directive 2009/128/EC aerial spraying is prohibited. A derogation is only possible in special cases under certain conditions. According to the German Plant Protection Act two exemptions are foreseen:
Aerial applications (helicopter, drones) are only allowed in steep slope vineyards and forest canopies. Drift values have been collected for drones only in steep slope vineyards at the moment. For drones, so far only applications of fungicides in steep slope vineyards were granted.
The approval or authorisation of aerial uses (including drones) of plant protection products are outlined in § 18 of the German Plant Protection Act.
The assessment is carried out by the competent authorities regarding efficacy, health and environment. For all uses of plant protection products with drones risk mitigation measures apply. For example, uses must be complied with a certain distance above the crop and flying speed.
The application of a plant protection product using aircraft requires an additional authorisation of the competent authorities of the German Federal States.
There might be a potential for drone application in other crops. It would allow an application in difficult terrain or a treatment of only certain areas in the field. The challenges are the current legal framework conditions within the EU and DE and the drift and impact in comparison with conventional spraying in field crops.
The poster will give an overview of the authorisation process for applications of plant protection products with drones in Germany. It will show the current status for risk assessment and management. Furthermore, it will highlight the potential and challenges for a future possibility of applications with drones in further crops.

6.07.P-Tu471 Beyond Default Mixture Allocation Factor-settings: How Can We Increase the Applicability and Scientific-relevance of Mixture Risk Assessments for Metal(oid)s?

***Charlotte Nys**[1], Karel Viaene[1], Karel Vlaeminck[1], Maria Laura De Donno[2], Marius Schmitt[2], Koen Oorts[1], Marnix Vangheluwe[1], Hugo Waeterschoot[3], Lara Van De Merckt[3] and Karel De Schamphelaere[2], (1)ARCHE Consulting, Belgium, (2) Ghent University, Belgium, (3)Eurometaux, Belgium*

The European Commission calls in the Chemicals Strategy for Sustainability for a systematic investigation of the impact of combined exposure into chemical risk assessments under REACH. To cover for such effects a default Mixture Allocation Factor (MAF) of 5 is under discussion, which most probably will imply that the safety limit of single substances will be reduced. Analysis shows that the implementation of a default MAF will have a large impact on the environmental risk assessment of inorganics (including metals and metalloids). Given that metal(oid)s are naturally occurring, the implementation of such a MAF may result in exceedances of safety limits at natural background concentrations, suggesting a combined risk. However, to our knowledge, a specific MAF for metal(oid)s has not yet been derived, as most existing studies do not consider metal(oid)s. In addition, default MAF calculations include different levels of conservatism which originate from the underlying mixture model, i.e., concentration addition (CA). These conservatisms include that I) all substances have the same mode of action, II) all substances contribute to the mixture toxicity, and III) for all substances the same species drives the environmental threshold (e.g., PNEC).
To anticipate the mixture toxicity correction under REACH, we evaluated the relevance of the proposed default MAF for metal(oid)s. This was done by calculating a metal(oid)-specific MAF (with the MAFceiling-approach) using European-wide monitoring databases, considering both the presence of

metal(oids) and their co-occurrence with organic substances in freshwater systems. In addition, the conservatisms in default MAF settings was assessed via the I) Mixture Interaction Factor (MIF), which expresses the conservatism of CA-mixture predictions relative to observed mixture effects at regulatory relevant effect levels ; and the II) Margin of Safety (MoS) expressing the conservatism of applying CA-based risk assessment models at the ecosystem level (PNEC) rather than at the species-level (EC10). In addition, based on these calculations a tiered scheme to incorporate mixture risks in environmental compliance assessment of REACH-regulatory dossiers for metal(oid)s is proposed. The proposed scheme incorporates default MAF settings as a baseline screening tier, and scientific-relevant refinements (e.g., MIF, MoS, bioavailability, biodiversity-effects) in higher tiers.

6.07.P-Tu472 Ecotoxicological Biomonitoring Ising in Situ Caging of Gammarus sp. (crustacea): Large and Local Scale Implementation in France

Caroline Arcanjo[1], Olivier Geffard[2], Dorothee Bolzan[3], Amelie Vlandas[3], Berangere Pergeline[5], Luc Pereira-Ramos[5], Baptiste Casterot[5], Magali Barnier[6], Sylvain Jolly[6], Jean-Pierre Rebillard[7], Jonathan Canal[7], Yohan Laigle[8], Cecile Dubois-Coli[8], Olivier Fontaine[8], Xavier Bourrain[9], Olivier Perceval[10], ***Anthony Gérard Edouard Mathiron**[11]* *and Guillaume Jubeaux[12], (1)BIOMAE, France, (2)INRAE RIVERLY, France, (3)Artois Picardis Water Agency, France, (5)Seine Normandie Water Agency, France, (6)Loire Bretagne Water Agency, France, (7)Adour Garonne Water Agency, France, (8)Rh ne-Mediterranee-Corse Water Agency, France, (9)Clermont-Ferrand University, France, (10)Office FranCais de la Biodiversite, OFB, France, (11)Biomae, France, (12)Biomae, CHÂTEAU GAILLARD, France*

The WFD requires European Union member states to protect and restore water bodies to reach good chemical status. To this end, France has implemented, a strategy based on active biomonitoring using in situ caging of Gammarus sp. to measure priority substances, check the compliance with biota-EQS (i.e., environmental quality standard) and assess trends with national thresholds, called BBAC (i.e., bioaccumulation background assessment concentration). In parallel with this chemical monitoring, this method offers the opportunity to carry on ecotoxicological measurements. Indeed, assays based on biological responses (i.e., bioassays) are relevant to evaluate both exposure and effect of chemicals as they integrate all bioavailable chemical substances. Deployment has been performed on 5 hydrographic basins based on 3 campaigns per year from 2019 to 2024. Unspecific (survival, feeding activity and fertility rate) and specific (acetylcholinesterase activity and endocrine disruption) biological markers were measured. This proposal aims to (1) present feedback on the collected data over 6 years and (2) present results for two case studies at large and local scales.

Gammarids are collected in breeding ponds, kept under laboratory conditions and calibrated before in situ exposure. Males and females are distributed respectively in 5 cages (20 males per cage) or 4 cages (7 females per cage). Depending on bioassays, in situ exposure lasted for one (feeding and AChE activity) to three (fertility rate and ED effect) weeks. Endpoint measurement was performed according to French AFNOR standards protocols XP-T90-722-1, XP-T90-722-2 and XP-T90-722-3.

Between 2019 and 2024, 3.079 caging were performed (i.e., 358 stations and 16 campaigns). 97% of the caging systems were successfully retrieved.

The present study shows that in situ caging of Gammarus sp. has been successfully implemented in France since 2019 to assess water bodies ecotoxicity. Concerning the large-scale study, i.e., French water agency basins, the results highlight that the feeding and fertility rates were the most discriminating responses. This allows the ranking of stations according to their level of toxicity and monitoring trends over time. In the same way, at a local scale (i.e., river) in situ caging of Gammarus sp. has proven to be an effective tool to objectify sources of toxicity.

6.07.P-Tu473 Current Risk Assessment of Non-Target Terrestrial Plants Under the Regulation (EU) 1107/2009: Deficit Analysis and Recommendations for the Revision of the Terrestrial Guidance Document

***Harry Byers**[1]*, *Magali Sole[1], Caroline Baudson[2], Laura Mathieu[2], Hana Kubatova-Hirsova[3], Sweba Ghani[1], Stephan Brendel[1], Cecile Perillon[1] and Steffen Matezki[1], (1)German Environment Agency (UBA), Germany, (2)Health Food Chain Safety Environment, Belgium, (3)Central Institute For Supervising and Testing in Agriculture, Czech Republic*

The current Terrestrial Guidance Document (SANCO/10329/2002) was adopted 22 years ago, and 7 years before the Regulation (EC) No. 1107/2009. It neither reflects the latest scientific developments nor does it adequately incorporate the provisions of the Regulation (EC) No. 1107/2009. The European Food Safety Agency (EFSA) has acknowledged various shortcomings in its review of the current state of scientific knowledge for the risk assessment of Non-Target Terrestrial Plants (NTTP) exposed to pesticides (EFSA 2014 Scientific Opinion). Since then, no progress has been made in the development of a terrestrial guidance document. Finally, in June 2024, EFSA received a mandate from the European Commission for the revision of the Terrestrial Guidance Document. Due to the long delay there is the question whether EFSA's reviews from 2014 remain up to date.

This study focuses on the NTTPs and aims to identify recent scientific advancements since the publication of the EFSA 2014 Scientific Opinion. To achieve this, we carried a comprehensive literature review. In total, 2137 papers were identified following a query on various databases (Scopus, web of science), combined with a snowball search. After an initial assessment, 192 studies were considered relevant for the revision of the terrestrial guidance document for NTTPs and attributed to different topics of the NTTP risk assessment (e.g. Effect, Exposure, Calibration, Higher-tier).

Besides identifying new deficits, the definition of the deficits presented in EFSA 2014 has been also updated. Key findings included: more recommendations on the representativeness of the species tested, the mode of action of the substance under evaluation and improvements to exposure models (e.g. implementation of a MAF). More guidance for tests evaluation, SSD simulation or higher tier studies are needed. One of the main deficit of the risk assessment scheme was the lack of calibration for the tiered approach. As already reported in EFSA 2014, the need to develop specific in-field Protection Goals for NTTPs, to address their role in habitat and food web support, was confirmed.

This aligns with the general protection goals outlined in (EC) 1107/2009 and related legislative documents. Considering these recommendations in the forthcoming revision of the Terrestrial Guidance document would make a significant regulatory advancement regarding a better protection of NTTPs and a further strengthening of biodiversity as legal protection goal.

6.07.P-Tu474 Reproductive Endpoints and Phenological Stage Exposed in Non-Target Terrestrial Plants Studies: A Meta-Analysis Using a Percentile Approach and Consequence for Risk Assessment Under (EU) 1107/2009

Sweba Ghani[1]*, Cecile Perillon*[1]*, Thomas Graff*[1]*, Harry Byers*[2]*, Caroline Baudson*[3]*, Hana Kubatova-Hirsova*[4]*, Stephan Brendel*[1] *and Magali Sole*[1]*, (1)German Environment Agency (UBA), Germany, (2)German Environment Agency (UBA), France, (3)Health Food Chain Safety Environment, Belgium, (4)Central Institute For Supervising and Testing in Agriculture, Czech Republic*

Currently, only vegetative endpoints are evaluated and considered in the risk assessment of Non-Target Terrestrial Plants (NTTPs) under the European Regulation (EU) 1107/2009 for pesticides. However, evaluating pesticide effects across the entire plant life cycle from seed germination and seedling stages to juvenile development, flowering, seed production, and subsequent germination is essential for assessing their overall impact on natural plant populations and safeguarding biodiversity (EFSA 2014).

While prior studies have shown that vegetative endpoints may not be adequately protective with respect to reproductive endpoints in NTTPs, a recent meta-analysis from 2019 identified no NTTP taxa as particularly sensitive to reproductive outputs. However, this analysis relied on comparing average values. This statistical approach is nonetheless considered insufficient for regulatory purposes as it might not account for sensitive species. Consequently, for regulatory purposes, percentile-based approaches are usually applied to ensure protection of a broader range of species, such as the 10th percentile, rather than relying solely on central measures like the mean or median.

This study aims to update the dataset used in the meta-analysis from 2019 with data from the past decade and reanalyze it using a percentile-based approach. In addition to comparing vegetative and reproductive endpoints, we examine the impact of the phenological stage during exposure. Specific recommendations will be made regarding the inclusion of reproductive endpoints in ecotoxicological testing and/or in risk assessment. The findings are intended to support the forthcoming revision of the Terrestrial Guidance Document launched by the European Commission in June 2024.

6.07.P-Tu475 German Court Judgement: The Right to Environmental Information Grants Access to ERA Data and Studies from the Human Medicinal Product Authorisation Procedure – Recommendations for its Implementation

Carolin Floeter[1] *and Susanne Schwonbeck*[2]*, (1)University of Applied Sciences Hamburg, Germany, (2)Fraunhofer ITEM, Germany*
The pollution of pharmaceuticals in the environment is of concern and risk mitigation measures should further be developed. Environmental risk assessment (ERA) is part of the EU authorisation procedure of veterinary /human medicinal products (VMP/HMP) since 1998/2006, but the availability of these data for the field of environmental protection is limited.

In a German court judgement of historic importance, the relationship between access to environmental information here data and studies of the ERA of medicinal products for the plaintiff one the one hand, trade and business secrets or intellectual property rights from the pharma industry on the other hand was fundamentally clarified:
The ERA data and studies of active pharmaceutical ingredients of the authorisation procedure are environmental information on emissions. Thus, trade or business secrets cannot be held against the right to environmental information. Intellectual property rights was from the pharma industry not convincingly presented, because the procedures required by the EMA guidelines using standardized methods, even if it were, there would be a weighed up in which the public interest would prevail.
In conclusion, the competent authority is required to grant the plaintiff access to the complete ERAs, i.e., all documents of the submitted dossier required under Annex 1 part I. module 1. point 1.6. "environmental risk assessment" of Directive 2001/83/EC and information for each of the selected substances (medicinal products) (ECLI:DE:VGK:2023:0713.13K5068.18.00).

By clarifying the accessibility of ERA data and ERA studies, the German court has made a groundbreaking decision with European implications [1].
Beside the judgement, recommendations for its implementation, derived on a multidisciplinary stakeholder workshop with participants from e.g. Federal Environmental Agency, waste water treatmentent and drinking water authorities, universities and resarch institutes will be presentated.

6.08 Regulatory Risk Management of Chemicals Integrating Risks, Impacts and Socio-Economic Assessments for Robust Policy Decisions

6.08.T-01 Why Should we Integrate Risks, Impacts and Socio-economic Assessments for Speeding-up the Phase-out and Substitution of Harmful Chemicals?

Silke Gabbert[1] *and Arianne de Blaeij*[2]*, (1)Safety of substances and products, RIVM, Bilthoven, Netherlands, (2)RIVM, Netherlands*
The European Chemicals Strategy for Sustainability Towards a Toxic-Free Environment intends to facilitate decision-making and regulatory efficiency towards a fast phase-out of the most harmful chemicals by applying the essential use (EUSE) concept. In REACH authorisation and restriction procedures, in contrast, socio-economic analysis (SEA) has served as a decision-support tool for regulatory risk management of chemicals. It has repeatedly been argued that the SEA approach is too inert to ensure an quick phase-out or substitution of chemicals. In contrast to REACH, a comparative assessment as required under the Biocidal Products regulation (BPR) has not been worked out in detail yet. Based on an explorative analysis, we spell-out key requirements for the EUSE concept to achieve its aims, and discuss what this implies for impact assessment and cross-disciplinary integration of information. Our analysis reveals that, compared to a SEA and other forms of comparative approaches used in European chemicals legislations, decision-making based on the EUSE concept considers the benefits of regulatory measures only. Information about negative impacts or damage costs of a ban (in case the use of a chemical deems non-essential), or an exemption of a ban (in case the use of a chemical deems essential), is ignored. Such simplification will likely reduce the need for cross-disciplinary integration of knowledge and data. While this may save time, disregarding such relevant information can lead to robust policies only if specific requirements are met. It requires, for instance, to reliably detect chemical uses which are truly (non-)essential, i.e., for which it is clear a priori that all positive impacts (social benefits) of a derogation, a phase-out or a substitution exceed all negative impacts (social costs). This process requires to define unambiguous criteria for assessing the necessity and criticality of chemical uses in relation to societal goals, including measurable indicators, assessment tools and, ultimately, decision-rules. Likewise, criteria and corresponding methods for the assessment of acceptable alternative substances and technologies have to be defined. For the majority of harmful chemicals, unequivocal conclusions on the (non-)essentiality of a chemicals use will likely be impossible. This provides strong arguments for strengthening the integration of risk and impact information into SEAs, capturing all non-market impacts of chemical policies.

Disclaimer/Disclosure: We wish to thank the Dutch Ministry for Infrastructure and Water Management for financial support under the Impulse Program.

6.08.T-02 An Ecosystem Service Impact Assessment Framework Applicable to Any Chemical Pollutant

David Spurgeon[1]*, Sarah Roberts*[1]*, Felicity Hayes*[1]*, Thea Sletten*[2]*, Zachary Leather*[2]*, Ece Ozdemiroglu*[2] *and Rob Tinch*[2]*, (1)UK Centre for Ecology and Hydrology (UKCEH), United Kingdom (2)eftec Economics for the Environment Consultancy, United Kingdom*

"Chemical pollution affects species, ecosystems, and their ability to deliver services, creating costs that must be balanced against economic benefits. Managing these impacts is challenging due to the diversity of pollutants to be assessed, extensive data gaps, and insufficient knowledge on the links between ecotoxicology and ecosystem services. This issue often lead to a reliance on precautionary risk assessments. To address the challenge of chemical impact assessment in a more holistic manner, we outline a proposed framework that integrates information on chemical hazard, exposure, ecological effects, and impacts on ecosystem services. Steps of the framework are detailed below.

- Step 1: Hazard Ranking – Chemicals are ranked into potency groups using HC50 values from species sensitivity distributions (SSDs) and alternative data (e.g. from QSARs). Additional hazards elevate potency levels.
- Step 2: Exposure Ranking – Chemicals are ranked by environmental concentration and detection frequency, adjusted for persistence and mobility.
- Step 3: Community Impact Assessment – Combines potency and exposure to estimate species-level impacts and taxonomic group sensitivity.
- Step 4: Ecosystem Service Impacts – Links taxa declines to ecosystem processes and services, quantifying reductions in services like pollination and nutrient cycling.

The framework was tested for three case study chemicals. For fipronil, the high potency and exposure could be linked to impacts on insects and nematodes. For copper, moderate-high potency and exposure could be linked to affects on plants, microbes, and some invertebrate taxa. For perfluorohexane sulfonic acid the framework indicated effects on vertebrates, affecting services like game and food provision.

The proposed assessment framework links chemical hazards and exposure to ecosystem impacts, enabling assessments for chemicals with varying data levels. Demonstrated through case studies, the framework offers insights into the ecosystem service costs of chemical pollution, guiding risk management and decision-making.

6.08.T-03 Integrating Risk and Socio-Economic Assessments to Support Decision-Making in Soil Remediation

Elvia Rufo[1]*, Silke Gabbert*[2] *and Arianne de Blaeij*[2]*, (1)Vrije Universiteit Amsterdam, Netherlands, (2)Dutch National Institute for Public Health and the Environment (RIVM), Netherlands*

In an era of pressing environmental challenges, there is a growing need for comprehensive decision-making frameworks that integrate scientific, economic, and social dimensions. Traditional approaches to chemical risk management, relying predominantly on risk assessments, fail to adequately address the socio-economic implications of ecological hazards. To bridge this gap, we propose an integrative framework combining ecotoxicological risk assessment with socio-economic evaluation, aimed at enhancing the depth and relevance of decision-making processes for soil remediation. As part of the EU-ARAGORN project, we conducted a systematic literature review to examine how existing socio-economic analyses (SEA) have addressed the impacts of soil remediation strategies. The review highlights the lack of a harmonized approach to SEA, emphasizing that the selection of remediation impacts and the parameters for assessing impacts is case-specific. The expected impacts of remediation will differ, for example depending on pollutant properties, spatial scale, remediation technologies, and intended land-use after remediation. Building on lessons from existing guidance frameworks and advancements in toxicology and economic theory, we developed a flexible decision-support tool tailored to varying data availability and site characteristics for different methodological levels (T1-T3). The framework evaluates social costs and benefits including environmental, human health, and (wider) economic impacts. This allows for qualitative, quantitative, or monetized comparisons of remediation strategies. Moreover, these levels ensure adaptability to diverse contexts, supporting multi-criteria decision-making and stakeholder engagement. With an application to a case study in Moldova Noua (Romania), the framework aims at supporting decision-making processes for soil remediation not only by facilitating the translation of scientific data into accessible formats such as spatial maps, but also informed choices by integrating ecological and socio-economic considerations. The framework thus shows the importance of sustainable and economically viable soil remediation strategies.

Disclaimer/Disclosure: This research has been conducted as part of the EU ARAGORN project funded by the Horizon Europe Research and Innovation Actions programme under grant agreement N° 101112723

6.08.T-04 Using Price Incentives to Substitute Hazardous Chemicals in the European Union
Daniel Slunge[1]*, Matti Vainio*[2] *and Thomas Sterner*[1]*, (1)University of Gothenburg, Sweden, (2)University of Helsinki, Finland*
The presence of hazardous chemicals poses significant threats to human health and ecosystems. Substances of Very High Concern (SVHCs), as identified under the EU s REACH Regulation, are among the most problematic, yet progress in reducing their use remains limited due to regulatory challenges and high administrative costs. This study proposes the introduction of economic incentives, specifically fees, to accelerate the substitution of SVHCs with safer alternatives.
We evaluate two fee models tailored to the EU context: (1) company-based annual fees, inspired by Massachusetts Toxics Use Reduction Act (TURA), and (2) tonnage-based fees, comparable to the EU s plastic tax. Using data from the European Chemicals Agency (ECHA) on SVHC usage and authorization applications, the study models the potential substitution effects and revenue generation under various scenarios.
Results indicate that a tonnage-based fee of 800 per tonne could reduce SVHC usage by up to 79% in high-volume sectors, while generating significant revenues for reinvestment in research and innovation. Conversely, company-based fees, though less effective in driving large-scale substitution, enhance compliance and provide targeted incentives for smaller firms to explore safer alternatives. Annual revenues from this approach could range between 2 million and 27 million, depending on the scope and design.
Our findings demonstrate that economic instruments like SVHC fees can complement existing regulations by promoting cost-effective substitution, innovation, and reduced health and environmental risks. Further research is needed to refine fee structures and explore mechanisms for revenue recycling to support industry transitions toward non-toxic solutions.

6.08.P Regulatory Risk Management of Chemicals Integrating Risks, Impacts and Socio-Economic Assessments for Robust Policy Decisions

6.08.P-Tu477 A Framework to Break Down Silos Across Disciplines and Enable More Holistic Decisions and Communication: Case Study for Octocrylene Environmental and Public Health
Jennifer K. Saxe*, Kurt A Reynertson and Sagar Thakali, Kenvue, United States*
Octocrylene, an ultraviolet light filter (UVF) ingredient in sunscreens, has been proposed for restriction in the EU under REACH, underpinned by a regulatory environmental risk assessment (ERA). In the US, an expert committee convened by the National Academies of Sciences, Engineering, and Medicine published a comprehensive review of the environmental fate, exposure, and effects of UVFs. They identified key knowledge gaps preventing rigorous ERAs for UVFs and raised concerns that regulatory decisions about sunscreen ingredients could influence human behavior and health outcomes. Specifically, communication regarding the environmental safety of UVFs could result in negative perception and reduced use of sunscreens products with established cancer prevention benefits.

We created a framework for quantitatively linking decision-making and communications about sunscreens to changes in their public perception, availability, use and accompanying health outcomes. This framework applies to any scenario where communication about one set of product attributes (e.g., desirability, safety) could result in unintended harm through a cause-and-effect chain leading to adverse public health outcomes. The framework uses data, models, and collaboration across disciplines, including environmental, behavioral, and medical sciences, economics, public health, and epidemiology, and is meant to break through specialists silos, leading to better decisions and communications.

The framework is applied to the EU octocrylene review, which occurs in a region where numerous alternative UVFs are available due to the classification of sun protection products as cosmetics. If a decision is made using a conservative, precautionary approach for environmental safety, any reduced sunscreen use and concomitant adverse health outcomes could be mitigated by ready access to alternative UVFs in the EU. However, in the US there is a relative lack of alternative UVFs because sunscreens are regulated as medicinal products, creating barriers to market entry. We show that, due to rapid global information dissemination, public communications about any EU octocrylene decision could have unintended negative consequences for US public health.

This framework provides a more holistic view, linking ERA, perception and behavior, and public health, and demonstrates the importance of collaboration across disciplines and geographies to improve communications and avoid unintended public health outcomes.

6.08.P-Tu478 Transferable Quotas for PFAS in the EU

*Matti Vainio[1] and **Daniel Slunge**[2], (1)University of Helsinki, Finland, (2) University of Gothenburg, Sweden*

Four EU Member States and Norway made a proposal to restrict Per- and Polyfluoroalkyl Substances (PFAS) on 13 January 2023. During public consultation on the restrition ECHA received an unprecedented number of 5600 comments. These alone already demonstrate the ubiquous use of PFAS in the society. It has been very challenging for ECHA s scientific committees to give opinions on the proposed restriction and ECHA has not been able to tell when its opinion would be adopted. This indicates that the Commission will also have substantial challenges to decide on how PFAS should be restricted in an proportionate manner.

In the paper we discuss if it was possible to set a condition based on transferable quotas allowing the continued manufacture, placing on the market or use of PFAS instead of a ban if it would lead to disproportionate socio-economic impacts. Alternatively, a specific legal instrument could be created in the EU to complement the restrictions on PFAS.

The use of transferable quotas would be a new way of encouraging substitution by setting an ambitious reduction target for all PFASs and letting the market operators, i.e. the manufacturers and importers of the PFAS, to find cost-effective ways of reaching the target through transferable quotas. Such system is already being used under EU s Fluorinated greenhouse gas regulation (2024/573), which phases out by 2050 industrial chemicals -- which are also PFASes. This regulation includes all necessary elements and would thus be a relevant starting point also for PFASes.

EU s Emission Trading System in greenhouse gases has some helpful elements that could be included in the transferable quota system for PFASes, in particular the possibility to bank and transfer quota. With some modifications, in particular through a possibility of banking and tranferring the quota more flexibly, and adapting the infrastructure -- e.g. the F-gas portal to an PFAS-portal -- the proposed system would be encourage innovation and thus substitution and be at the same time market friendly.

We will also discuss briefly which PFAS could be regulated through the transferable quota system.

The decision on a transferable quota system would be made in the EU based on qualified majority, like a revision of the REACH Regulation. It could be done as part of the revision of the regulation, either concurrently or in parallel.

6.08.P-Tu479 Chemical Stock Pollution Modelling to Determine the Environmental Impact of Emission Intervention Measures for Persistent Mobile and Toxic Substances: The case of PFOA

*Johannes Meesters, Joris T.K. Quik, Emiel Rorije, Matthias Hof, **Silke Gabbert** and Arianne de Blaeij, RIVM, Netherlands*

Persistent, mobile and toxic substances pose increasing long-term environmental and human health risks, because environmental concentrations incline as long as emission rates exceed degradation rates. Intervention measures, for instance for perfluoroalkyl and polyfluoroalkyl substances, minimize emissions, but the pollution stock due to past emissions can remain high for decades or even centuries. We present an approach to determine the environmental stock arising from different regulatory interventions affecting emissions from production, use, and end-of-life of products applying dynamic stock pollution modeling with the multimedia fate model SimpleBox. Regulatory interventions differ with regard to the type and timing of emission reduction scenarios. The assessment is conducted for perfluorooctanoic acid (PFOA) in Western Europe and its environmental stock in air, water, sediments and soil predicted over the period of 1951-2050. The interventions evaluated are (i) the industrial initiatives in 2002 to phase-out PFOA production, its use as formulation agent and on-site emissions and (ii) the European Union s legal restrictions on PFOA that came into force in 2020. Life cycle mass flow data was used to construct a realistic emission scenario including interventions, which is compared to five hypothetical scenarios in which (i) intervention measures were never taken, (ii) no new PFOA was produced or used after 2002 (iii) restrictions in 2020 never came into force (iv) reductions of the amount of PFOA emitted per amount used or produced at industrial plants were the only interventions and (v) the production of PFOA and its use was reduced with 50% after 2002. Results demonstrate that environmental stocks in air, soil and sediments on a continental scale could effectively be reduced after emission interventions taken in 2003 and 2020. However, PFOA emitted in the past is hardly being degraded, but was instead displaced from continental fresh waters to global ocean waters. The stock in global oceans as a result of past Western European emissions poorly declines but would continue to incline if no interventions were taken. These insights demonstrate that dynamic stock modeling proves to be a useful tool for evaluating the effectiveness of regulatory interventions usually affecting emissions. This gives relevant and clear decision-support to prioritizing and selecting risk management measures to policy makers, which can be integrated in socio-economic analyses.

6.08.P-Tu480 A Stepwise Prioritization Approach Towards Effective Regulatory Measures of PMT/vPvM Substances in the REACH Registration Database

Michael Neumann[1]*, Hans Peter H. Arp*[2]*, Sarah Hale*[3] *and Ivo Schliebner*[4]*, (1)IV 2.3 Chemicals, German Environment Agency (UBA), Germany, (2)Norwegian Geotechnical Institute (NGI), Norway, (3)German Water Centre (TZW: DVGW-Technologiezentrum Wasser), Germany, (4)German Environment Agency (UBA), Germany*

PMT (Persistent, Mobile, Toxic) and vPvM (Very Persistent, Very Mobile) substances pose significant intrinsic hazards due to their ability to cause long-lasting and diffuse contamination of water resources, which can lead to adverse effects on human health and the environment. The Classification, Labelling and Packaging (CLP) Regulation ((EC) No 1272/2008) ensures a high level of protection of health and the environment. A core principle is the 'self-classification' of a substance or mixture by the manufacturer, importer or downstream user. The classification is based on the hazardous properties of a substance or mixture and not on the likelihood of exposure and risk considerations. On 20th April 2023 the new hazard classes PMT and vPvM entered into force.

Prioritization is crucial for regulation as it enables the efficient allocation of resources to address the most significant risks posed by hazardous substances, ensuring that regulatory actions are targeted where they are needed most. It helps identify substances that require immediate attention, facilitating timely risk management measures to protect public health and the environment. Additionally, prioritization highlights data gaps and areas needing further research, guiding stakeholders in developing effective strategies for monitoring and remediation efforts.

The stepwise prioritization approach towards effective regulatory measures of PMT/vPvM substances in the REACH registration database developed by the German Environment Agency (UBA) consists of three steps. The first step involves the identification and classification of the intrinsic hazard of PMT/vPvM substances, focusing on their potential to cause harm. The second step focuses on the prioritization of PMT/vPvM substances for regulation based on their and exposure levels and potential risk to drinking water sources.

The third step involves the prioritization of regulatory measures based on their effectiveness. This step ensures that regulatory actions are targeted, effective, and proportionate to the risks posed by PMT/vPvM substances. Ultimately, this step aims to implement regulatory actions that effectively minimize the environmental emissions of hazardous PMT/vPvM substances while promoting safer alternatives.

The stepwise prioritization approach is a critical tool for identifying effective regulatory pathways to mitigate emissions of high-priority PMT/vPvM substances, such as 1H-Benzotriazole, 1,4-Dioxane, and Melamine.

Disclaimer/Disclosure: Acknowledgement This research project was funded by the Federal Ministry for the Environment, Nature Conservation, Nuclear Safety and Consumer Protection (BMUV) with Project No. (FKZ) 3719 65 408 0

6.08.P-Tu481 An Attempt to Establish Recycled Plastic Grades Focusing on Plastic Additives to Enable Appropriate Recycling

Kyoko Ono*, Masashi Gamo, Naohide Shinohara, Naoya Kojima and Isamu Ogura, Advanced Industrial Science and Technology, Japan*

Promoting plastic recycling is an increasingly important issue from the perspective of resource recycling

and preventing plastic pollution. Determining the hazards and risk of the chemicals in the recycled plastic is difficult because the recycled plastics are made from a variety of plastic wastes, such as used plastics and leftovers from the production of plastic products. However, if such risks are not assessed and managed, concerns remain that resource-efficient recycling of plastics come to a standstill or remain limited.
This study aims to develop a grading concept for waste plastics and recycled plastics. The risks associated with the use of recycled plastics come from plastic additives, contaminants, and by-products contained in plastics (hereinafter referred to as plastic chemicals). Therefore, a risk-based grading approach for recycled plastics is developed by conducting a trial grading of recycled plastics based on a risk assessment framework for chemicals contained in plastics.
We assumed that the grade of recycled plastic was determined according to the risk of the chemical substances contained in the plastic. This risk corresponds to the hazard ratio related to the risk of plastic chemicals for a specific recycled plastic in a specific use case. The hazard ratio is expressed as follows: $C \times L \times M \times E / T$
where C is the concentration of the plastic chemical(s) in the recycled plastic; L is the leaching characteristic of the plastic chemical(s); M is the migration factor for correction according to the scenario/exposure route; E is the exposure factor of the usage scenario; and T is the toxicity of the plastic chemicals, for example, the upper exposure limit. If it can reasonably be assumed that the magnitude of the hazard ratio corresponds to the quality of the recycled plastic, the following range is set for one grade:
$0.1 < (C \times L \times M \times E/T) < 1$ (Equation 1a)
Or, if we consider the hazard ratio for plural plastic chemicals cumulatively,
$0.1 < \Sigma(Ci \times Li \times M \times E/Ti) < 1$ (Equation 1b)
where i: individual plastic chemicals.
To separate the portion that depends on the substance from the portion that depends on the usage scenario, Equation 1b is transformed as follows: $0.1/(M \times E) < \Sigma(Ci \times Li/Ti) < 1/(M \times E)$ (Equation 2)
The value of "$1/(M \times E)$" will be a separator of each grade.
We obtain the parameters M and E to ensure that the value(s) of "$1/(M \times E)$" applies to various use cases and exposure scenarios (including exposure route) in plastic products in Japan.

6.08.P-Tu482 The Qualitative Quotient: The Importance of Applying Mixed Methods to Understand Circularity of Hospital Plastics

***Nikoline Oturai**, Tiffany Ramos, Joy Ndwiga and Kristian Syberg, Roskilde University, Denmark*

The healthcare sector, while aiming to protect human health and wellbeing, has a significant negative impact on the climate and environment due to massive resource use and waste production. The Circular Economy, designed to preserve resources in closed-loop value chains, has gained global attention but lacks practical implementation. This study focuses on the challenges of implementing circular economy initiatives for single-use plastics in hospitals, with a specific emphasis on practitioner involvement. The scientific literature on single-use plastics in hospitals primarily uses quantitative methods, such as life cycle assessments and waste audits.
This study suggests that using mixed methods (combining quantitative and qualitative measures) can provide insight into the day-to-day reality of medical staff and their unique perspectives on healthcare practices. This study focuses on the healthcare sector's environmental impact and the implementation of circular economy initiatives for single-use plastics, which directly addresses the 'triple planetary crisis' of pollution, climate change, and biodiversity loss. By integrating social elements and practitioner perspectives, the research highlights the complex interplay between human health, environmental sustainability, and regulatory frameworks. The mixed-methods approach offers a comprehensive understanding of the challenges and opportunities in reducing pollution and resource use in healthcare, contributing to the broader goals of improving EU chemicals legislation and promoting integrated solutions.
The presentation will show preliminary results from a mixed-methods, multi-partner, research project rooted in the circular economy principles, CircleHealth, which seeks to identify barriers to reducing single-use examination gloves at Danish hospitals.

6.08.P-Tu483 A Circular Economy of Chemicals Roadmap for the UK

***Miriam Fsadni**, Elizabeth Gibson and Matthew Royle, Newcastle University, United Kingdom*

Ethylene is one of the most important chemicals manufactured globally, a platform chemical for a vast array of products. The olefins ethylene and propylene account for >70% of all organic chemical production, including polyethyleneglycols via ethylene oxide which are used in cosmetics, pharmaceuticals, lubricants and paints. To defossilise olefin production and support the UK s pledge to achieve net zero carbon emissions by 2050, a pathway to a circular economy of chemicals is needed. The aim of this research project is to prepare a roadmap, showing the current status and future prospects of the circular economy of olefins.

A whole systems approach is used to identify the challenges and opportunities associated with the transition from a linear to a circular model. This involves looking at the availability of new technologies, and also the business, economic, societal and political landscape. The roadmap draws on consultations with stakeholders, for a holistic view of the chemical industry and related supply chains. These include SME and multinational companies from the pharmaceutical and personal care industries.

Within this framework, the roadmap looks at fostering resource efficiency, reducing carbon emissions, replacing petrochemical feedstocks and reducing waste. This includes: evaluating new and established technologies; identifying products or feedstocks for circular routes; identifying where new standards and testing may be required; as well as understanding where conflict or competition with other sectors may arise. The roadmap also aims to highlight where policy change is planned and needed in order to make the transitions in the required time, and provide a structure on which to compare progress and impact internally and externally.

6.08.P-Tu484 Implications for Implementing the "Essential-Use" Concept in Chemical Regulations
Romain Figuière[1]*, Zhanyun Wang*[2]*, Juliane Gluge*[3]*, Martin Scheringer*[3]*, Armin Siegrist*[3] *and Ian Cousins*[1]*, (1)Stockholm University, Sweden, (2)Swiss Federal Laboratories for Materials Science and Technology (Empa), Switzerland, (3)ETH Zurich, Switzerland*
The Stockholm Convention and the EU REACH Regulation are two key regulations on chemicals at the global and European level, respectively. Discussions have taken place on how to improve them and make them more efficient. For instance, the European Commission is considering implementing the essential-use concept in the REACH Regulation to guide decision-making for phasing-out the uses of the most harmful chemicals. Here we shed light on how the essential-use concept may alter and improve existing regulation by evaluating how existing regulatory outcomes would compare to outcomes derived using the concept and by identifying reasons for discrepancies, including a case study. Overall, this study suggests that existing regulations already consider elements of the concept in their decision-making, and that no drastic changes in the processes are necessary to implement the concept. For the authorities to properly assess the uses of a substance of concern, the industry would need to provide more technical information if they wish to obtain a derogation for their use, similar to the REACH Authorisation process. Further work should investigate what kind of and how much information would be enough to determine whether a use is necessary for health and safety, or is critical for the functioning of society.

6.08.P-Tu485 Ecotoxicological Hazards of Lithium and Its Salts and Regulatory Risk Management Measures
Odile Kerkhof*, Stephane Jomini and Cecile Michel, ANSES French Agency for Food, Environmental and Occupational Health & Safety, France*
Lithium has geogenic sources, thus it is naturally found in the environment in varying concentrations. Lithium and its salts (lithium carbonate, chloride and hydroxide) are widely used by industries and consumers, in particular in the rechargeable battery sector. Following a classification proposal of the 3 lithium salts (lithium carbonate, chloride and hydroxide) as toxic for the reproduction under the CLP Regulation 1272/2008/EC (on classification, labelling and packaging of substances and mixtures), and considering the growing uses and the new mining projects being developed in Europe, the French Agency for Food, Environmental and Occupational Health and Safety investigated the environmental hazards of lithium and its salts. The objective was to determine whether further regulatory risk management measures are necessary for the environment. The investigation was based on relevant studies from the registration dossiers under the Registration, Evaluation, Authorisation, and Restriction of Chemicals (REACH) regulation and scientific literature. Lithium showed chronic toxicity for three trophic levels (algae, invertebrates and fish) and could meet the criteria for harmonised classification under the CLP Regulation. Lithium also induced developmental defects in several species. Some endocrine disrupting properties were also evidenced. Finally, it induced phytotoxicity in various plant species. There is an urgent need to determine the extent to which human activities contribute to environmental occurrence and effects of lithium. Based on these outcomes, this work highlighted the need to derive an ecotoxicological reference value and to perform risk assessments for its uses throughout the life cycle. Regulatory actions such as e.g. CLP classification, measures under the Water Framework Directive should be considered.

6.08.P-Tu486 D.N.A-based Development of Chemical Accident Prediction and Risk Assessment Technology

***Yoon-Kyung Gwak**, Sun-Min An, Jun-Sang Lee and Ho-Hyun Kim, Research Institute for Living and Industrial Environment in Seokyeong University, Korea, Republic of*
The number of casualties in chemical incidents increase steadily despite the systematic management of chemical substances since implementation of the Chemical Substances Control Act in 2015.
A chemical accident is the uncontrolled and unintentional release of chemical substances, which could potentially result in impair to public health and the environment. Depending of the chemical properties, it can cause even greater damage human and the environment. Although the domestic chemical industry has made rapid growth, it has not followed by safety awareness of chemical substances and preparedness of chemical accident management. In chemical accidents, it is important to strengthen the initial response and establish a systematic prevention system.
This research institute has developed and established models of D.N.A-based chemical accident prediction and risk assessment technology for preventing chemical accidents since April 2022. The two models based on data from government agencies and chemical companies. The chemical accident prediction model utilized data such as the subscription status of employment and industrial accident compensation insurance in Gyeonggi-do, the current status of hazardous chemical handling companies in Gyeonggi-do, and the current status of hazardous chemical accidents in Gyeonggi-do. The chemical accident risk assessment model utilized data provided by the National Institute of Chemical Safety, meteorological data, and NFPA 704 risk codes. We has currently conducted additional data analysis and preprocessing to enhance the current platform, and plan to apply two models to companies in Gunsan-si to verify the effectiveness. Additionally, the causes of chemical accidents are not only technical defects, but also environmental and social factors. Thus, we plan to establish a process prediction model that includes environmental and social factors. This process includes data on SOP, instructions, and maintenance.
The chemical accident prediction platform developed by this research institute can be utilized basic data for policy establishment in related fields in the future, and assist chemical accidents prevention by local governments and companies.

This work was supported by Korea Environment Industry & Technology Institute(KEITI) through Advanced technology development project for predicting and preventing chemical accidents Program(or Project), funded by Korea Ministry of Environment(MOE)(2022003620003)

6.08.P-Tu487 Risk-based Approach for Regulation of Marine Pollution

***Kirit Wadhia**, NOV, United Kingdom*
Introduction: It is apparent that regulations worldwide exist for management of marine pollution dealing with different industry sectors. There is diaparity between the different frameworks employed and even within. Criteria for different sectors require particular and specific considerations.
Concern of marine pollution impinges on the change pertaining to physical, chemical, and biological state of the water bodies and coastal areas. The 1982 UN Convention on the Law of the Sea defined marine pollution as: the introduction by man, directly or indirectly, of substances or energy into the marine environment which results or is likely to result in such deleterious effects as harm to living resources and marine life. (UNCLOS, 1982). The most significant threat is the potential impact on marine wildlife and ecosystems.
Chemical pollution in general can emanate from a range of sources including crude oil and other petroleum products, antifoulants, pesticides, pharmaceuticals and personal care products.
In context of the petroleum sector industrial discharge (i.e. produced water) containing chemicals from anthropogenic and natural sources is of primary concern.
The offshore oil and gas industry thematic strategy (Offshore Strategy) sets the objective of preventing and eliminating pollution and taking the necessary measures to protect the OSPAR maritime area against the adverse effects of offshore activities so as to safeguard human health, conserve marine ecosystems and, when practicable, restore marine areas which have been adversely affected.
Risk assessment involves evaluation taking into consideration the potential direct and indirect consequences. It involves comparison of the exposure of the ecosystem to chemicals of pertinence & concern with the sensitivity of the ecosystem for these chemical through the specific exposure-route.
Perspective pertaining to the regulatory framework with insight of developments, considerations and progress concerning risk-based approach for the management of produced water discharges is the focus of this conveyance.

UNCLOS. (1982). United Nations Convention on the Law of the Sea. Available at: https://www.un.org/Depts/los/convention_agreements/texts/unclos/UNCLOS-TOC.htm

6.08.P-Tu488 Exposure Based Risk Assessment for Absorbent Hygiene Products

***Taryn Kirsch**[1] and Anders Lars Thelin[2], (1)Procter & Gamble, Germany, (2)Essity, Sweden*

Disposable absorbent hygiene products (AHPs) (diapers, menstrual products) have made an important contribution to the quality of life and skin health of millions of people. Regulatory classifications vary across countries, regardless of that, human health risk of products needs to be assured with due diligence. This can be achieved through a classical toxicological approach of hazard identification, exposure assessment followed by risk assessment to mitigate any safety concern of intentional as well as unintentional presence of substances. Although the intentional ingredients, which construct the AHPs, are well characterized from a safety perspective, it is the possible presence of trace chemicals that prompts NGOs, regulators and other stakeholders to challenge the product safety for consumers. EDANA volunteered to champion a transparent trust building initiative to self-regulate trace chemicals possibly present in AHPs, using scientific and standardised methodologies. The Stewardship Program CODEX consists in a list of trace chemicals purposely chosen, guidance values for each substance (class) and a standardized test methods (CEN Workshop Agreement 18062) to evaluate products for possible traces of substances. The CODEX values are connected to the respective test methods and the values as such should be decoupled from safety aspects, as they are based on regulatory/standard limits and do not include the aspect of actual human exposure. It needs to be noted that the method is producing very conservative results as it allows for a more intensive extraction of potentially present chemical substances from the product than under normal conditions. Test results based on the CODEX analytical method represent the amount of chemical that is extractable from the product under the experimental conditions. Extractables, based on the CODEX analytical method are not directly comparable to migratable limits that are derived from scientific exposure limits. Detection indicates the mere presence of certain trace chemicals in a complex product matrix like baby diapers or sanitary napkins and is only indicative of a hazard, but not indicative of safety or risk of using these products. Exceeding CODEX limits does not necessarily mean the products are unsafe. Exposure Based Risk Assessment (EBRA) is needed to assess whether the detected concentration of a chemical substance carries any risk from consumer safety perspective.

6.08.P-Tu489 A Tragedy of the Commons – The Case of the Lake Kutubu Indigenous Fishery in Papua New Guinea

***Ross Smith**, Hydrobiology, Australia*

Lake Kutubu is the second largest lake in Papua New Guinea, and is a Ramsar Listed Wetland because The Lake s extraordinary level of endemicity (10 of the 14 fish species found there are endemic to the lake itself) exceeds that of any other lake in the entire New Guinea-Australian region (RAMSAR 2024 Nov 18). The fishes have been a crucial component of the traditional diet of the Foe People of the lake, and they have had both a traditional custodian role as well as a legally recognised role in management of the lake ecosystem since the lake was identified as a Wildlife Management Area under the Fauna (Protection and Control) Act. However, there are increasing concerns regarding the effects on the fishes and the fishery of the development of an oil and gas industry in the region, and the associated increase in road links and regular air services to the lake catchment.

Although there have been claims of direct impact of the petroleum industry on the lake (Smith et al. 2015; Schneider et al. 2016; Elapa 2024 Oct 16), the Foe are also well aware of the impacts of their own increasing population growth and increased access to modern fishing technologies on the fishery. The introduction of exotic fishes into the lake has also complicated the management of the native fisheries, even though a method to eradicate one of the exotic species has been suggested (Thresher et al. 2020). This paper will summarise the circumstances that have contributed to the current challenges to manage the fishery and the lake ecosystem, including collaboration with the Foe people over the last 15 years to better understand the pressures and stressors affecting the lake.

Disclaimer/Disclosure: The author thanks the Foe People for their friendship and support and the fianancial and technical support of Oil Search, SANTOS, the Conservation and Environmental Protection Authority and the National Fisheries Authority over the course of 15 years of study of Lake Kutubu.

6.08.P-Tu490 Revitalizing Indigenous Knowledge in Global Climate Science and Policy Processes

***Beatrice Olutoyin Opeolu**[1] and Linda Sibali[2], (1)BEE Solutions and Consultancy Services, South Africa, (2)University of South Africa, South Africa*

For over 350 million indigenous peoples worldwide, climate change impacts are expected to be early and severe due to their location in high risk environments. Climate change impacts pose existential threat to millions of indigenous peoples across the globe. Indigenous knowledge systems are critical to the achievement of SDG 13 (Climate Action). Climate change effects include heat waves, severe storms, drought and diseases with consequent implications on ecosystems, human health and socio-economic systems. Major drivers of climate change are resource utilization-driven activities. These are exacerbated in the developing world by lack of infrastructure, poor governance and poverty. Issues of water scarcity, biodiversity loss, loss of livelihoods due to extreme weather events continue to negatively impact global ecological and human health systems. A paradigm shifts in practices to incorporate indigenous knowledge into production systems, management and governance of natural resources is now critical for a sustainable world. Agriculture, medicine and natural resources management require holistic approaches for a sustained future. Insights into some of these issues and possible mechanisms for effective stakeholder engagement for tangible impacts in the context of a developing country will be provided.

6.08.P-Tu491 Energy Efficiency, Effectiveness, and Derivatives Assessment in the Crop Agricultural Sector: Parametric and Non-Parametric Methods Application Review

Hamza Taoumi *and Khadija Lahrech, Sidi Mohamed Ben Abdellah University (USMBA), Morocco*

Energy scarcity and natural resource availability are the main challenges facing crop agricultural researchers and scholars worldwide. Consequently, searching for their optimization becomes an essential path to follow to guide policymakers in establishing strong strategies aiming to attain sustainability. Several methods exist in the literature to choose among the practices to apply for energy and resource consumption optimization in the crop agricultural sector. Two essential methods were the subject of an updated and critical review of the crop agricultural research articles contributions to the energy performance evaluation according to their mapping, their functions, their aspect, and the energy variable occupation degree: The Data Envelopment Analysis, and the Stochastic Frontier Analysis. Based on peer-reviewed research recorded from 2019 to 2023, 28 original articles existing in the literature were gathered from the databases Scopus and Web of Science to dig deeply into the energy efficiency, effectiveness, and derivatives evaluation through the DEA and SFA application. The analysis showed that those methods are the basic methods used for energy performance evaluation, and the energy occupies a significant role as a primary variable to be included in the optimization problem solving as an input, output, or influence factor to follow during different ecosystem stages. Thanks to the DEA and SFA multidimensional consideration of different aspects and variables in the optimizing equation, it could be concluded that the energy variable is a primary path among others to follow during the entire stages of the ecosystem evaluation. Such an approach would help policymakers define strategies to obtain more goods while focusing on energy consumption and wastes, economic costs, environmental damages, and social impacts.

6.09.P Almost there? Latest News on Pollinator Risk Assessment in the EU

6.09.P-We508 Bee Risk Assessment in the Real Regulatory World

Jutta Muether*, Aleksandra Zakrys-Zalewska and Kari Moshenberg, GAB Consulting GmbH, Germany*

The EFSA Bee Guidance Document (EFSA Bee GD, 2013) significantly updated the simple approach of the prior guidance (SANCO/10329/2002 rev 2, 2002). In 2023, EFSA published the revised Bee GD. The risk assessment scheme has increased in complexity by integrating various exposure pathways into a comprehensive evaluation of their overall impact on colony health. At the time of abstract submission (November 2024) this guidance is not adopted or implemented for use in the European Union pesticide regulatory procedure. Amongst stakeholders, there is no agreement on whether to follow EFSA s recommendations and several alternative approaches are in place.

All the aforementioned guidance covers only chemical plant protection products (PPPs) and lacks directives for addressing non-chemical PPPs like microbials and natural substances. Such substances play an important role for the target to reduce the use and related risk of chemical pesticides as well as the use of the more hazardous pesticides by 50% by 2030.

Currently, there is no harmonised approach on bee risk assessment. Perspective on a timeline for implementation of the revised EFSA Bee GD is still lacking, leading to a high level of uncertainty for applicants as well as for evaluators who work for national authorities.

During this transition period member states and regulatory zones defined their own strategies. There are several national approaches either following an in-between solution or specific national or zonal approaches, such as the Northern Zone approach including a specific calculator tool for chronic bee risk assessment.

Further challenges are emerging for biopesticides and naturally occurring substances, which often do not fit into the classical risk assessment and testing scheme used for chemical PPPs.

For microbial substances and PPPs, specific data requirements are now in place, but there is still a lack of agreed test guidelines and approaches how to address infectivity/pathogenicity in the different test systems.

To meet the goals set for the reduction of the use of PPPs, application techniques such as spot or precision

application are supported. However, there is no consistent guidance for how to model or reflect these approaches in risk assessment calculations or in the performance of higher Tier bee studies.
The presentation will share the perspective of a regulatory consultant on the current bee risk assessments as evaluated by various member states for different substance types.

6.09.P-We509 First Practical Experiences with Equivalence Testing in Pesticide Risk Assessment for Bees

Silvio Knaebe[1], *Pierre Mack*[2] *and Holger Bargen*[2], *(1)Eurofins Agroscience Services US, Germany, (2)Eurofins Ecotox, Germany*

Equivalence testing was first introduced in the context of pesticide risk assessment in the new draft guidance document for the risk assessment of pollinators (EFSA 2023). The methodology is already used in clinical trials to compare different formulations of the same group. It is a statistical method that aims to prove the safety of a substance by demonstrating that any potential effects are smaller than the predefined acceptable threshold of 10% (?).
Equivalence testing contrasts with traditional difference testing, which aims to detect statistically significant differences between a treatment and a control group, often leading to inconclusive results regarding safety. In contrast the equivalence testing directly addresses the safety of a substance by aiming to prove the absence of relevant effects. Additionally, it allows researchers to directly control the risk of failing to detect a high-risk substance (false-positive rate). This error is of primary concern to risk assessors. The outcome of an equivalence test directly informs the conclusion regarding high or low risk, unlike difference testing which may lead to inconclusive results.
A further key advantage according to EFSA is that the study design can adapt to the level of concern associated with the plant protection products (PPP). No specific replication level is mandated, power analysis can inform the applicant about the likelihood of proving safety given specific effect size assumptions. Studies of high-concern PPPs may require more resources (e.g., replications) than those of low-concern PPPs.
This data explores the application of equivalence testing wit data based on a real study. Using a mock dataset based on real field studies with a low-concern pesticide, we investigated the feasibility of equivalence testing with in vivo data from honeybee colonies. Our analysis included assessing colony strength across various field pair combinations and time points. Results demonstrate the potential of equivalence testing to effectively evaluate pesticide safety, even with the high natural variability observed in bee colonies. Notably, our findings suggest that the required number of field pairs for robust assessment may be lower than current EFSA recommendations, highlighting the potential for resource optimization in risk assessment studies.

6.09.P-We510 Learnings from a Failed Meta-Analysis: Sub-Lethal Effects of Plant Protection Products on Bees - A Case Study

Tobias Pamminger[1], *Magdalena M. Mair*[2] *and Christian Maus*[1], *(1)Bayer AG, Germany, (2) University of Bayreuth, Germany*

Chemical plant protection products are designed to manage pests, weeds and disease in a wide range of crop plants ensuring stable yields. While effective in limiting pest populations they can come in contact with non-target organisms including bees. Such unintended exposure can result in a range of side effects including, among others, sub lethal ones such as altering movement, learning and feeding behavior. While the existence of such effects is well documented in bees, there have only been a handful of attempts to quantitatively assess their occurrence across products and species. In this study we attempted to fill this gap by performing a formal meta-analysis on the occurrence, strength, and potential dose dependency (sequence of effects) of sub lethal effects in adult bees moving beyond a simple analysis of their existence. We find an extensive bias in the existing data both in terms of product x species tested with the majority of studies focusing on insecticides targeting the nicotinic acetylcholine receptor (e g. Imidacloprid and Clothianidin) in the honeybee. In addition, we find that a large proportion of the studies do not adequately report the necessary methodological details and results to reliable extract the statistical information necessary to conduct a formal meta across chemical plant protection and the different types of sub lethal effects. We discuss the cause and consequences of these finding for studying sub lethal effects in bees beyond their existence and provide recommendations to improve the reporting standards of such studies.

Disclaimer/Disclosure: TP and CM work for the Bayer AG a manufacturer of plant protection products.

6.09.P-We511 Effect Models for Higher-Tier Risk Assessments: The Example of SolBeePop_ecotox, a Population Model for Solitary Bees

Amelie Schmolke[1], *Nika Galic*[2], *Vanessa Roeben*[3], *Thomas G. Preuss*[3], *Mark Miles*[4] *and Silvia Hinarejos*[5], *(1)RIFCON GmbH, Germany, (2)Syngenta Crop Protection AG, Switzerland, (3)Bayer AG, Germany, (4)Bayer AG, United Kingdom, (5)Sumitomo Chemical, France*
In the revised bee guidance document released by EFSA (2023), ecological effect models are recognized as useful tools to support higher-tier pesticide risk assessments for bees. Models can be applied to support study data and extrapolate from tested to untested situations, e.g., differing environmental conditions. For solitary bees, models additionally could be used to extrapolate to untested species given the large diversity of species and ecologies. Natural as well as managed populations could be addressed. With the population model for solitary bees, SolBeePopecotox, we demonstrate the application of a model that can be applied in support of higher-tier risk assessments. The model can be used to simulate multiple solitary bee species, using their species-specific ecological traits as parameters. Exposure routes are considered explicitly, including direct spray, residues in pollen and nectar as well as in nesting materials. Effects are implemented in the model using a simplified toxicokinetic-toxicodynamic model, BeeGUTS, adapted specifically for bees. The performance of the model was demonstrated using available data from semi-field studies with the red mason bee, Osmia bicornis L., simulating bees foraging in tunnels over control and insecticide-treated oilseed rape. In addition, we applied the model to simulate hypothetical semi-field studies with untested soil-nesting solitary bees species, the alkali bee, Nomia melanderi COCK., and the hoary squash bee, Eucera pruinosa SAY. With this example of a population model for solitary bees, we demonstrate how models could be evaluated and analysed, and how their applications could support higher-tier risk assessments of bees. Evaluation and applications of ecological models can provide insights into their acceptability for use in pesticide risk assessments, supporting the pathway to become standard tools in risk assessments as envisionend by the EFSA guidance document as well as other regulatory frameworks.

6.09.P-We512 Bumble-BEEHAVEecotox – A Mechanistic Effect Model for Bumblebees
*Dominik Lammers, Thomas G. Preuss and **Vanessa Roeben**, Bayer AG, Germany*
Pollinators, particularly bumblebees, are essential for ecosystem health and agricultural productivity. However, understanding the impacts of various stressors, including pesticides, on bumblebee colonies presents significant challenges for environmental risk assessments. This study aims to develop a framework for Bumble-BEEHAVEecotox, an ecotoxicological module for the Bumble-BEEHAVE model, to predict effects at the colony level based on laboratory data from individual standardized studies.

The Bumble-BEEHAVEecotox framework will be built upon the existing BEEHAVEecotox template and will proceed in two main steps. First, we will implement the capability to simulate tunnel studies, which will involve accurately defining landscape parameters and setting up bumblebee colonies at specific locations with precise timing. This will allow us to judge Bumble-BEEHAVEs ability to simulate bumblebee colony dynamics. The second step will integrate two effect modules: one based on the dose-response relationship used in BEEHAVEecotox and another utilizing the General Unified Threshold model of Survival (GUTS).

Our model will be validated through semi-field studies, starting with control studies to evaluate baseline colony dynamics, followed by studies that incorporate plant protection products to compare predicted effects with empirical data.

Bumble-BEEHAVEecotox represents a significant advancement in understanding the impacts of environmental stressors on bumblebee populations. By enabling comparisons of various stressors, including landscape changes and pesticide applications, this modular modeling framework can inform more effective risk management strategies and contribute to the conservation of pollinator populations in changing landscapes.

6.09.P-We513 Simulations of Population-Level Effects of Pesticides on Abundance and Pollination of Bumble Bees in Landscapes of Different Composition Allow the Identification of Critical Application Levels
Andreas Focks[1], *Leonhard Urs Bürger*[1], *Steven Droge*[2], *Daniel Paredes Llanes*[3], *Jose Paulo Sousa*[3], *Grzegorz Sylwester Sowa*[4], *Louise Wipfler*[2] *and Lorraine Maltby*[4], *(1) Osnabrück University, Germany, (2)Wageningen UR, Netherlands, (3)University of Coimbra, Portugal, (4)University of Sheffield, United Kingdom*
This study aims to enhance the environmental assessment of non-target organisms (NTAs) concerning plant protection products (PPPs) by linking individual impacts to effects on ecosystem functions. Simulation models that analyze the population dynamics of sensitive species, like non-managed

bumblebees in agricultural settings can create such links. Specifically, we examine the effects of a hypothetical pesticide on bumblebee populations and their pollination function across landscapes to establish critical application rates that affect bumblebee populations and pollination services.
Bumble-BEEHAVE is an individual-based model designed to analyze bumblebee foraging behavior based on floral resource availability and environmental factors. Implemented in the BEE-STEWARD software using NetLogo, the model was adapted for this study by incorporating a pesticide module that simulates the pesticide's fate and effects. The model accounts for pesticide emissions, decay, and calculates the increased mortality risk for foraging bumblebees using a log-logistic dose-response function. We simulated Bombus terrestris exposure in a 25 km² agricultural landscape in South England (Fowey) after a hypothetical pesticide application on day 90 with various initial concentrations ranging from 0.1 to 100 ?g/m² and a derived DT50 of 20 days and an LC50 of 2.4 ?g/m².
Simulations illustrated the negative impact of increasing pesticide concentrations on bumblebee abundance and pollination performance. As pesticide concentrations increased, both bumblebee abundance and foraging visits decreased. A dose-response analysis highlighted the possibility to derived critical concentration thresholds necessary to restrict bumblebee population inhibition to under 10%. Furthermore, action at a distance was observed, with pollination in non-exposed natural areas diminishing at intermediate concentrations of the pesticide. This research demonstrates the utility of simulation models in linking individual-level effects of PPPs to broader ecosystem functions, considering ecological traits, chemical properties of pollutants, and landscape dynamics. Through these simulations, critical thresholds for pesticide application levels can be established to protect vital ecosystem services like pollination.

Disclaimer/Disclosure: The authors thank Mathias Becher for support with the Bumble-BEEHAVE model and EFSA for funding the project number OC/EFSA/ED/2021/02.

6.09.P-We514 B-Risk, A Calculator Tool Implementing the Latest EFSA Bee Guidance Document

*Dagmar Bemelmans[1], Rachel Sharp[2], Alessio Ippolito[2], Csaba Szentes[2], Franco Maria Neri[2], **Alberto Linguadoca**[2] and Jose Cortinas Abrahantes[2], (1)Open Analytics, Belgium, (2)European Food Safety Authority (EFSA), Italy*

EFSA has reviewed its guidance document (EFSA, 2013) on the risk assessment of plant protection products and bees (Apis mellifera, Bombus spp. and solitary bees). The reviewed guidance document, published in 2023, outlines a tiered approach for exposure estimation for different scenarios, it includes updated hazard characterisation and provides risk assessment methodology for all bee groups. Performing lower tier risk assessments according to this guidance requires complex exposure estimations for the different scenarios and routes of exposure, fitting dose-response curves for different risk cases and combining the exposure and hazard estimations to predict the colony or population level effects. In addition, several specific aspects covered in the guidance (e.g. time reinforced toxicity, mixture toxicity) require some computations.
In light of these complexities, the creation of a calculator tool was deemed necessary by EFSA. The tool is is available as a Shiny app on the EFSA R4EU platform. It will also be made available in the future for all interested stakeholders in the Knowledge Junction repository as an R package which could be also used locally for knowledgeable R users. A first testing phase of the tool was performed in the first half of 2024 with the involvement of several member state experts and stakeholders representing chemical industry. The tool was published in early November 2024 and is accompanied by a detailed manual.
The poster will explain the main modules of the tool and will illustrate some functionalities.

6.09.P-We515 BeeGUTS R Package, Mechanistic Modelling of Bee Survival for Environmental Risk Assessment Following EFSA guidelines

*Carlo Romoli[1], Benoit Goussen[1], Liubov Zakharova[1], Marie Trijau[1], Erik B Muller[1], **Vanessa Roeben**[2] and Thomas G. Preuss[2], (1)ibacon GmbH, Germany (2)Bayer AG, Germany*

The use of GUTS modelling for the analysis of survival data has been recognized as a powerful tool for environmental risk assessment. Recently, the BeeGUTS model has successfully opened the possibility to analyze all the laboratory tests done on adult bees (acute and chronic) within a single mechanistic TKTD framework, allowing to derive a single set of test-independent GUTS parameters. The BeeGUTS R package implements this method in an open-source, user-friendly tool. The calibration of the model parameters is performed using Bayesian inference through the robust Stan platform. With the package, it is possible to perform all the steps described by EFSA for calibration and validation of a GUTS model. The most recent update of the package introduces the tools for calculations required by the EFSA guidance on bees, such as the time reinforced toxicity test, and it expands the usability for the various steps of the risk assessment process using TKTD modeling.

6.09.P-We516 GUTS for Bee TRT Assessment: A Methodology Comparison

Torben Wittwer, Alexander Singer, Mariana Perez, Oliver Jakoby, Marcus Metz and ***Amelie Schmolke****, Rifcon GmbH, Germany*

The revised EFSA guidance on the risk assessment of pesticides on bees, likely becoming effective in 2025, requires the assessment whether a substance exhibits Time-Reinforced Toxicity (TRT) properties. TRT of a substance is indicated if exposure to low doses over long time periods causes higher effects in organisms than higher exposure over short periods. For this assessment, the reduced versions of the General Unified Threshold Models of Survival (GUTS-RED) are employed. Thereby, two versions of the model, using the assumptions of stochastic deaths (GUTS-RED-SD) or individual tolerance (GUTS-RED-IT), are calibrated to data from an OECD 245 chronic oral toxicity study on adult honey bees, and the LDD50 is estimated for 27 days, i.e., for the life span of summer bees. This calculation step is included in the risk calculator tool under development by EFSA. However, there are multiple other software implementations of GUTS models openly available, including multiple R packages and openGUTS. We used several alternative software options available for GUTS to calibrate to hypothetical chronic study data. We compared the predicted LDD50s and resulting conclusions of the TRT hazard assessment. If similar, the comparison can improve confidence in model outputs. Discrepancies might point to issues with calibration data or software implementations. We think this approach is an important step in the reliable application of GUTS-RED in lower-tier risk assessments of bees.

6.09.P-We517 Introduction of a New Interest Group for Bee Modelling in the Context of ICPPR

Amelie Schmolke[1]*, Jeffrey Minucci*[2]*, Vanessa Roeben*[3] *and Johannes Luckmann*[1]*, (1)RIFCON GmbH, Germany, (2)US EPA Office of Research and Development, United States, (3)Bayer AG, Germany*

Mechanistic effect models have been identified as relevant tools in the context of risk assessments of bees and other pollinators in guidance documents in the EU and North America. Several models have been introduced for the purpose or are under development, spanning the representation of organism-level effects (GUTS), honey bee colony models and population models of non-Apis bees. In the context of the International Commission for Plant-Pollinator Relationships (ICPPR), an interest group for bee modelling was established in October 2024 with the aim of improving the acceptability and usability of effect models in bee risk assessments. The interest group provides a platform for exchange and discussions between stakeholders from different organisations including regulators, industry, CROs and academia as well as different professional backgrounds such as modellers, policy makers and bee experts. The interest group has the goal of identifying important steps that can improve model applications and support acceptability of models for risk assessments. Manageable projects relating to the identified steps will be conducted in the context of the interest group. We are presenting this effort at SETAC to interconnect the two communities and bolster communication.

The views expressed are those of the author only and do not necessarily represent those of the United States or the US EPA. In general, the views expressed in this presentation and by the interest group do not necessarily represent those of the authors' or members' affiliations.

6.09.P-We518 Integrating Landscape-Scale Simulations with TKTD Models for Pollinator Risk Assessment

Florian Schunck[1]*, Andreas Focks*[1]*, Leonhard Urs Bürger*[1]*, Christopher J. Topping*[2] *and Xiaodong Duan*[2]*, (1)Osnabrück University, Germany, (2)Aarhus University, Denmark*

Landscape-scale simulations are gaining prominence in environmental risk assessment as comprehensive tools for evaluating the impacts of chemicals in complex ecosystems. Toxicokinetic-toxicodynamic (TKTD) models, like the general unified threshold model for survival (GUTS), are well-established for assessing toxic effects under realistic exposure scenarios but have limitations when applied to spatially explicit, individual-based models. These challenges include solving differential equations for each agent at every timestep and addressing species-specific adaptations for multiple uptake routes, common in terrestrial organisms.

Here, we present the integration of the "buffer GUTS" model, a generic TKTD framework capable of handling multiple uptake routes without requiring species-specific information. This model is calibrated to parameterize the relative contributions of each uptake route to the overall toxic effect. We achieve a computationally efficient solution by discretizing buffer GUTS into algebraic equations for state variables at each timestep. Additionally, we address the damage threshold problem by introducing an extra timestep when damage crosses the threshold within a single step, ensuring precision equivalence to ODE solutions. Our approach describes the buffer GUTS for oral, topical and contact uptake routes, and we demonstrate its application using the Osmia bicornis model from the Animal Landscape and Man Simulation System (ALMaSS) as a case study. This integration represents a scalable and precise method for coupling TKTD models with landscape-scale simulations, broadening the scope of environmental risk assessments to terrestrial and multi-route exposure scenarios.

6.09.P-We519 Integrating Allometric Scaling in Solitary Bee Risk Assessment: A Mechanistic Approach

Vanessa Roeben[1]*, Zhenglei Gao*[1]*, Mark Miles*[2]*, Tobias Pamminger*[1] *and Thomas G. Preuss*[1]*, (1)Bayer AG, Germany, (2)Bayer AG, United Kingdom*

Solitary bee risk assessment has been a challenge for a decade. Globally there is currently no agreed framework and testing strategy on how to conduct a solitary bee risk assessment. In the recent draft of the revised bee guidance for Europe, EFSA proposed so called Toxicity extrapolation factors (Tefs) to cover solitary bees based on honeybee data for the environmental risk assessment.
In the preparation for the new guidance, EFSA has done a rigorous job to collect data, evidence, and knowledge of solitary bees and have identified allometric scaling as a useful component for the bee risk assessment. With this work we take a logical next step to include allometric scaling in a scalable and flexible mechanistic risk assessment framework, based on the great data and knowledge collection of EFSA.
Our study will showcase that using honey bee as a surrogate for intrinsic sensitivity is protective for other bee species, based on the critical body burden approach. By integrating allometric scaling into the remaining parts of the risk assessment, we are separating sensitivity, exposure and vulnerability which allows us to use the honey bee as a surrogate for sensitivity and include exposure and vulnerability by simple equations or realistic models. Furthermore, we highlight the importance of energetic needs and protein consumption in reproductive health, linking these factors to body size and exposure levels. With the presented framework, we are reducing the complexity of solitary bee risk assessment by simplifying the approach based on sound scientific knowledge without additional experiments and thus enabling tailored risk assessments for locally important species.
Our findings contribute to the ongoing dialogue surrounding the EFSA bee guidance by proposing a structured methodology for risk assessment that is applicable across various geographical contexts.

6.09.P-We520 Realistic Field Exposure - Pilot Study on Refining Bee Exposure Residue Data: Comparative Analysis of Field and Tunnel Studies for Phacelia Crops

Silvio Knaebe[1]*, Pierre Mack*[2] *and Farnaz Faramarzi*[2]*, (1)Eurofins Agroscience Services US, Germany, (2)Eurofins Ecotox, Germany*

Bees are essential pollinators, and it's crucial to ensure that pesticides used in agriculture don't harm them. Currently, pesticide risk assessments for bees often rely on "worst-case scenario" data, which may overestimate the actual risk. To address this, the European Food Safety Authority (EFSA) has proposed new guidelines (EFSA2023) that allow for more realistic exposure estimates.

EFSA2023 outlines two main approaches for conducting bee field studies:
1. Minimum Alternative Forage Studies: These studies aim to create a worst-case exposure scenario by ensuring that less than 10% of the landscape within a 4 km radius of the study fields contains alternative forage resources. This setup ensures bees forage almost exclusively on the treated crop, maximizing residue exposure measurements in pollen and nectar.
2. Randomly Selected Landscape Studies: These studies are designed to represent realistic field conditions by selecting 15 locations across the intended area of pesticide use. Bees are exposed to treated crops within diverse landscapes, including natural forage, to measure residues under typical foraging conditions while maintaining statistical reliability for residue data

Despite this proposal as a refinement option, these approaches have not yet been implemented in practice. To gain some practical aspects and estimate realistic reductions in residues when transitioning from worst-case tunnel data to real-life field conditions we conducted a small Pilot Project
Our study compares residue data in pollen from two distinct settings:
• Field Set-up: Residues were measured at four Phacelia field sites.
• Tunnel Set-up: Residues were measured at two enclosed Phacelia tunnels.

All sites were applied at the same rate of a commercial pesticide and samplings took place at 3 different sampling intervals at 0, 1 and 3 days after the respective application. In total, we generated 10 residue values in the field and 6 values in the tunnels.
Residues in the field were reduced by more than 80% compared to the tunnel.
This comparative analysis aims to provide critical insights into the refinement of residue data for more accurate risk assessments for bees.

6.09.P-We521 A Case Study of Assessing Sublethal Effects to Honey Bees For A New Insecticide Considering the EFSA Revised Bee Guidance

Charlotte Elston*[1] *and Annette Kling*[2]*, (1)Syngenta, United Kingdom, (2)Eurofins, Germany

Due to growing concerns and specific calls for greater consideration of sublethal effects to protect bee populations, the EFSA revised Bee Guidance document (2023) suggests assessing sublethal effects of PPPs as part of the effect-tier assessment. The rationale for this is that large scale behavioural changes may interfere with important tasks, such as foraging, which have the potential to translate to colony level effects and hence the Specific Protection Goal (SPG) of colony strength. Behavioural abnormalities are quantitatively observed according to given categories in the OECD 245 honeybee adult chronic test guideline (moribund, affected, cramps, apathetic, vomiting). Some barriers to developing a more comprehensive assessment of sublethal effects include lack of standardisation, lack of proven link to the SPG of colony strength, subjectiveness of visual assessments and potential for unconscious bias.
We present a 10 day adult honeybee chronic study conducted according to OECD 245 with a new insecticide in development which included blind assessments of sublethal effects and mortality, where the treatment groups were not known to the assessors.
In the control and carrier control, no behavioural abnormalities were observed throughout the test period. In the treatment groups, behavioural abnormalities (affected bees, moribund bees, cramping bees) were observed in all test item treatment groups, at all assessments, throughout the entire observation period but was not dose dependant. Results from the blind assessments correlated well with the range-finder test which was not conducted blind, indicating that the current test methods for assessing sublethal effects are robust within the same laboratory (between different assessors in the same laboratory). However, categories of behavioural effects given in the test guideline are open to interpretation as with any visual assessment, and adding additional assessments could result in lack of standardisation between studies and a deviation from the test guidelines. Results generated in the 10 day laboratory feeding study were compared to higher tier studies with Apis and Non-Apis bees with this new insecticide in development and discussed.

6.09.P-We522 Toxicity Based Classification System for Bees: A Preliminary Study from Anses

*Sebastien Lambin, **Julie Ravat**, Pierre-Francois Chaton, Vanessa Mazerolles and Claire Bosquet, ANSES French Agency for Food, Environmental and Occupational Health & Safety, France*

The environmental classification of active substances, plant protection products and biocides is important information for hazard identification and communication. Whereas harmonised criteria exist for the aquatic environment, such harmonised hazard classification system is not available for other organisms.

For bees, hazard classification approaches are implemented in some European member states (e.g Sweden for Biocidal Products) and in countries outside EU (e.g Canada and USA for Plant Protection Products), sharing some similar criteria. The principle is to consider an acute toxicity endpoint (LD50) greater than 11 µg/bee as a trigger for classification of hazard to bees. This means that below this trigger of 11 µg/bee, a substance or a product containing the substance would be considered toxic for bees and a specific hazard pictogram implemented.

On the basis of data available in the European list of endpoints for active substances in plant protection products and biocidal products, our study aims to identify the type of active substances that could be considered as toxic to bees when considering the above trigger of 11 µg/bee. A focus will be made on acute toxicity data as these are basis of the proposed trigger proposed above for the hazard classification.

6.09.P-We523 Sensitivity Study Using the Imidacloprid Neocotinoid Toxicity Test for Native Bees of the Species Tetragonisca angustula (jatai)

Claudia Penalva[1]*, Michiel Daam*[1]*, Janete Brigante*[2] *and **Eny Maria Vieira***[1]*, (1)IQSC-USP, Brazil, (2)EESC-USP, Brazil*

Native bees play a fundamental role in pollination, contributing to reproducing approximately 90% of flowering plant species and 80% of economically important crops. However, pesticide contamination threatens this species' survival, resulting in reduced biodiversity in ecosystems and food supply. Therefore, it was necessary to determine safe doses of pesticides, such as imidacloprid, to ensure that the bee's function and survival are not compromised. The aim of this study was to determine the lethal concentration of the neocotinoid imidacloprid (commercial product) (LC50) and its lethal dose (LD50) for the jatai bee species (Tetragonisca angustula), To determine sensitivity through the acute toxicity test to exposure to this pesticide, adult bees were collected in the early hours of the morning and taken to the laboratory for the start of the toxicity test. The test which was carried out over a period of 6; 24; 48; 72 and 96 hours. The bees were kept under acclimatization in an incubator at a temperature of 28 °C, with food being replenished at all times during the test. The results of the study showed that imidacloprid has a considerable toxic effect on bees from 24 hours of exposure. During this period, the CL50 (1.0333 mg L-1) and DL50 (1.00271 ng i.a./bee) were determined for the commercial product, imidacloprid. It was observed that for imidacloprid at concentration of 0.8 mg L-1 the mortality rate was 55% in the first 24 hours, reaching 67% mortality during the 96-hour period, and for the highest concentration of 1.6 mg L-1 in the first 24 hours of the test the mortality rate reached 100%.

6.09.P-We524 Developments in the Biocides Risk Assessment for Bees

***Helena Crosland**, Cambridge Environmental Assessments, United Kingdom*

Until recently there has been no quantitative risk assessment of bees when exposed to biocides. This is in contrast to the risk assessment for pesticides, where the assessment of bees is performed in accordance with SANCO (2002). In addition, extensive updates of the pesticide assessment have been proposed in the form of the updated bee guidance EFSA (2013) and EFSA (2023).

In 2019 the European Chemicals Agency (ECHA) was mandated by the European Commission (EC) to develop guidance for assessing the risks to arthropod pollinators (including bees), and to specify the information required to enable a conclusion to be drawn by any evaluating authority. The result of this is new guidance on how to assess biocide risks to bees (ECHA, 2024). The guidance is very closely linked to the EFSA (2023) guidance, though with some notable differences primarily relating to the estimation of exposure from biocidal uses. In March 2024 ECHA hosted a webinar to introduce the guidance and provide a Q&A opportunity. The new guidance will apply to active substance approvals and biocidal product authorisations for which applications are submitted on or after 1 February 2026.

In this poster the key developments in the bee risk assessment for biocides will be summarised. This will cover: which PT types require an assessment for the risk to bees; the Specific Protection Goals (SPG); Data requirements; emission scenarios (exposure assessment); and the risk assessment itself. The implications of this guidance on biocidal product applications will be discussed.

6.10 From Nanomaterials to Advanced Materials: Challenges and Progress in Research, Industrial Application and Regulation

6.10.T-01 Integrated Approaches to Testing and Assessment (IATA) for MXenes MAX Phases and Advanced Carbon Nanomaterials

***Javier Alcodori**, Arantxa Ballesteros Riaza and Carlos Fito, ITENE - Instituto Tecnologico del Embalaje, Transporte y Log stica, Spain*

MXenes are two-dimensional (2D) nanomaterials made of transition metal carbides, nitrides, or carbonitrides, derived from MAX phases, which are layered ceramics with alternating layers of transition metals, carbon or nitrogen, and another element like aluminum or silicon. By selectively etching the 'A' element (typically aluminum) from MAX phases, ultra-thin, flexible MXene nanosheets are created. These sheets have high surface area, excellent electrical conductivity, and tunable surface chemistry, allowing modification through various functional groups.

In the SAFARI project, MXenes are being developed for industrial applications in conductive inks, glucose/lactate biosensors, and EMI shielding paints, all aligned with the European Commission's Safe and Sustainable by Design (SSbD) Framework.

The SAFARI project is developing an Integrated Approach to Testing and Assessment (IATA) to evaluate the risks and hazards of both MXenes and their precursor MAX phases. This approach combines in silico tools, in chemico studies, and in vitro methods, using New Approach Methodologies (NAMs) to assess the safety of these nanomaterials. The goal of the IATA is to create a roadmap for evaluating the potential environmental and health impacts of MXenes, ensuring their safety and sustainability.

The first step of the IATA focuses on defining the problem, assessing the risks, and identifying hazardous properties of MXenes and their production process. The second phase involves gathering existing data on exposure routes, toxicological and ecotoxicological profiles, and physicochemical properties from literature and regulatory reviews. In the third phase, the collected information will be evaluated to identify any gaps. In the fourth phase, toxicological and ecotoxicological tests, workplace monitoring studies, and physicochemical analysis will be conducted. A life cycle analysis will assess the environmental impact of MXenes. If data is insufficient to meet regulatory requirements, further testing will be performed, completing the risk analysis and identification of hazardous properties.

6.10.T-02 Nanomaterials Risk Assessment - A Regulatory Framework for Assessing the Variability of Nanoforms

Virginia Rodriguez Unamuno[1]*, Diana Mestre*[1]*, Laurence Deydier Stephan*[1]*, Radek Bombera*[1]*, Cyril Jacquet*[1]*, Wim De Coen*[1]*, Richard Cross*[2]*, Marianne Matzke*[3] *and Kai Benjamin Paul*[4]*, (1)European Chemicals Agency (ECHA), Finland, (2)UK Centre for Ecology and Hydrology, United Kingdom, (3)Blue Frog Scientific Limited, Finland, (4)Blue Frog Scientific Limited, Edinburgh, United Kingdom*

The assessment of nanomaterials poses challenges due to the variability in nanoforms (NFs), which, despite sharing chemical composition, differ in key characteristics like size, shape, and coating. Traditional chemical-based assessments fall short of addressing these complexities. The ECHA-funded project, "Nanomaterial Risk Assessment: A Regulatory Way Forward for Sameness and Grouping Approaches," seeks to create a regulatory framework that efficiently accounts for NF variability while ensuring comprehensive hazard evaluation and regulatory compliance.

Stage one of this project produced a draft framework for assessing sets of nanoforms using decision trees based on key NanoApp characterisers such as composition, size distribution, surface functionalisation, shape, and crystallinity. This phase included a thorough review of over 1,000 publications, analysis of 10 databases, and assessment of 20 validation techniques focused on REACH's Annex VI characterisers. The study highlighted existing tools, such as DF4nanoGrouping, NanoApp, and GRACIOUS, examining their effectiveness and limitations in defining sameness thresholds. The NanoApp emerged as a critical tool, suggesting that tiered assessments could minimise unnecessary testing when characteriser variations stay within specified limits.

However, further exploration is needed to refine thresholds and integrate environmental factors. The project's next stage will validate the proposed framework through case studies and stakeholder-engaged data collection, ensuring robustness and filling critical data gaps with comprehensive nanoform testing.

6.10.T-03 Occupational Safety and Health Profits from a Safe Design

Rolf Packroff *and Michaela Clever, BAuA - Federal Institute for Occupational Safety and Health, Germany*

The green and digital transformation is accompanied by a profound change in workplaces and working conditions. In line with the UN's global sustainability goals, green workplaces should be designed in a humane way. With this aim, the European Commission's 2022 Joint Research Center has published the concept of safe and sustainable by design of chemicals and materials (SSbD). In this introductory lecture, examples from development of fibrous materials should demonstrate how safe material design has grown historically. Conclusions for future development will be drawn.
It lasted until the seventies to understand that the causes for asbestos related cancers lie within their fibre morphology and biopersistence in the deep lung. This makes clear that other fibrous materials, e. g. mineral wools, ceramic or microglass fibres and whiskers could also pose a cancer risk. But the "fibre principle" also offers the opportunity for a safe design of new fibrous materials, the introduction of biosoluble mineral wools in the late nineties was a breakthrough for the profit of workers health.
Today sustainable development is driving the development and use of fibre materials. Carbon fibres play an important role in lightweight applications, Carbonanotubes are essential for energy storage systems. But for both classes of materials specific types have been identified as a risk to workers health during particle-releasing tasks. But, also criteria for a safe design were derived from this experimental results and physical considerations. It was confirmed, that rigidity of critical fibres plays an important role in frustrated phagocytosis, which was not proven for extremely thin single carbonano fibres with diameters in the range below 30 nanometer. For carbon fibres we observe the phenomenon, that only crystalline types with a high density lead to a significant release of critical fibre dusts at the workplace.
We have underpinned the SSbD concept with an approach for safe-to-use chemicals, materials and

products that includes also low-emission forms and safe processes beyond the "golden standard" of avoiding hazardous properties. In addition, risk research on nanomaterials has clearly shown that the development of new materials and material classes must be accompanied by the development of adapted methods for risk assessment and evaluation. Regulation must keep pace with innovation!

6.10.T-04 Improving the Uncertainty Evaluation for Nanomaterial Worker Exposure Assessment for SSbD

James Hanlon[1]*, Rebecca Nebbia*[2]*, Matthew Boyles*[3]*, Lang Tran*[4]*, Enrico Bergamaschi*[2] *and Davide Lotti*[5]*, (1)Ricardo, United Kingdom, (2)University of Turin, Italy, (3)Edinburgh Napier University, Italy, (4)Institute of Occupational Medicine (IOM), United Kingdom, (5)LATI Industria Termoplastici S.p.A, Italy*

One aspect within Safe and Sustainable by Design (SSbD) frameworks for nanomaterials (NMs) and nano-enabled products (NEPs) that needs to be considered is worker exposure. This is often supported by the use of exposure models or tools. With the use of these tools and models, there can be considerable uncertainty in their outputs. Within control banding (CB) tools for NMs, there are potential improvements and streamlining that could be performed for uncertainty analysis.

We present methodology that has been developed for assessing uncertainty using Theory of Scales of Measurement and the GUM (Guide to the expression of uncertainty in measurement) for worker exposure in NMs CB tools. This methodology consists of five steps. These steps are: 1) Defining the output quantity (i.e. the potential exposure); 2) Identifying the input quantities and their scale (nominal, ordinal, interval, ratio); 3) Defining the allowable basic operations and permissible statistics. At this stage, potential improvements can be added if it is not possible to define the uncertainty contributions; 4) Checking the mathematical model relating output quantity (i.e. the potential exposure) to the input quantities for any mathematical flaw for the scales of the input parameters. At this stage, potential improvements can be added; and 5) Accounting for possible improvements suggested in step 3.

This methodology has been demonstrated using a thermoplastic industrial case study on single-walled carbon nanotubes (SWCNTs) and a polycarbonate (PC) matrix in the CB tool, Stoffenmanager Nano. Within Stoffenmanager Nano there are potential improvements to uncertainty, such as quantifying the overall uncertainty. Using this case study, we have assessed the input parameters (such as handling of NMs) and the probability distribution using the exposure algorithm in Stoffenmanager Nano to identify potential improvements to the uncertainty assessment.

Our developed methodology for assessing uncertainty can also be used to investigate improvements in uncertainty evaluation for other nanomaterial control banding tools.

Disclaimer/Disclosure: The authors thank the SAbyNA project, European Union s Horizon 2020 research and innovation program under grant agreement No 862419 who funded this work.

6.10.T-05 Prospective Material Flow Analysis of Advanced Materials: Building a European Circular Economy?

Luis Mauricio Ortiz-Galvez[1]*, Lora Dameska*[2] *and Bernd Nowack*[1]*, (1)EMPA - Swiss Federal Laboratories for Materials Science and Technology, Switzerland, (2)Empa, Universite de Liège, Switzerland*

Most studies analyzing mass flows of nanomaterials only covered recycling as a sink compartment and do not cover recycling flows because the advanced material under study is not intentionally targeted for this purpose. Thus, this study aims to explore potential flows of advanced materials in future scenarios, focusing on the end-of-life and recycling stages, using graphene in tires, batteries, and concrete to showcase possible consequences of the material circularity approach and exemplify connections in a European circular economy context. We used the dynamic and probabilistic material flow analysis model and three prospective scenarios to explore potential flows and evaluate potential dynamic changes in the system if Europe moves towards a circular economy. According to the model and scenarios, technical sinks and compartments out of the system would be significantly influenced, while environmental compartments are slightly influenced. Finally, using the combined system (tires-batteries-concrete), we observed that concrete might be a final sink for materials in the future that was not considered previously. Therefore, more research is needed to understand the implications of graphene (and other materials) during recycling streams and evaluate the implications of using recycling residues as backfillers in concrete due to the potential challenge of accumulating mixtures, which might have an impact on the recyclability of concrete in the future.

6.10.P From Nanomaterials to Advanced Materials: Challenges and Progress in Research, Industrial Application and Regulation

6.10.P-Th368 Bioaccumulation of Silver Nanoparticles (AgNPs) Induces Autophagic Dysfunction in Adult Intestinal Stem Cells to Accelerate Functional Aging

***Zi-Yu Chen**, Cheng-Han Song, Shian-Jang Yan and Ying-Jan Wang, National Cheng Kung University, Taiwan (Greater China)*

Silver nanoparticles (AgNPs) are widely used in various consumer products due to their potent antibacterial properties. However, exposure to AgNPs presents significant biological and environmental risks. AgNPs induce acute toxicity through the disruption of autophagy. Moreover, our recent findings indicate that AgNPs cause long-term toxicity and impair intestinal function through lifetime bioaccumulation. However, it remains unclear whether, and how, AgNPs dysregulate autophagy in intestinal stem cells (ISCs) to accelerate aging. In this study, we used Drosophila as an in vivo model to investigate the role of autophagy in AgNP-induced adverse effects on longevity. We first demonstrated that early-life exposure to AgNPs leads to developmental lethality and reduces lifespan in a dose-dependent manner, consistent with our previous findings. Furthermore, AgNPs bioaccumulate in the adult intestine, resulting in the loss of intestinal integrity. Mechanistically, AgNPs cause autophagic dysfunction and subsequently reduce the ISC population in the adult posterior midgut as aging progresses. Interestingly, in the larval midgut, AgNPs induce both autophagy and apoptosis. Knockdown of autophagy-related genes in larval ISCs mitigates AgNP-induced toxicity during development, whereas overexpression of these genes in larval ISCs decreases survival following AgNP exposure. Taking together, our results suggest that AgNP-induced autophagic dysfunction in adult ISCs depletes the ISC pool, thereby accelerating aging and associated functional declines. This study provides the first evidence that autophagy in ISCs mediates AgNP-induced adverse effects at the molecular, cellular, and organismal levels.

6.10.P-Th369 Harmonisation of Daphnia sp. Standardised Protocols: Assessment of Nanomaterials's Behaviour

***Fabio Yu Chen**, Ana Lopes, Patrícia Veríssimo Silva and Susana Loureiro, University of Aveiro, Portugal*

The characterisation and behaviour assessment of nanomaterials (NMs) are crucial for harmonising Guidance Documents (GD) and Test Guidelines (TG) for ecotoxicity testing. These guidelines are essential in ensuring compliance with European regulations like REACH and improving risk assessment of NMs. The OECD GD No 317 outlines comprehensive recommendations for modifying existing OECD TGs for aquatic and sediment toxicological assessments of NMs, addressing the unique challenges of unstable NM and focusing on strategies to minimise agglomeration/aggregation and optimise dispersion stability during testing. This study aims to understand the behaviour of ZnO NMs, TiO_2 NMs, bentonite nanoclays and multi-walled carbon nanotubes (MWCNTs) (JRC supply) in stock dispersions and test medium (ISO) of Daphnia magna and the impact of various exposure methods in their stability, to adapt the OECD Acute Immobilisation Test (No. 202) for Daphnia sp. Activities involved 1) assessing the dispersion efficiency of the four NMs in stock dispersions, 2) evaluating the stability of the NMs in the ISO medium over time (48h) and utilising different experimental configurations to determine the influence of container material (plastic versus glass) and depth (plastic tube versus plastic petri dish) on NM behaviour. Results showed that stock dispersions of ZnO, TiO_2, and bentonite NMs exhibited reasonable stability in the stock dispersions (Milli-Q water), with TiO_2 NM demonstrating the highest stability over the 48h (30.23 ± 1.50 mV at 24h; 31.27 ± 11.87 mV at 48h), and bentonite the lowest. The NMs' zeta potential (?P) values fell within the range indicative of unstable colloidal dispersions (-30 mV to +30 mV) in ISO media. TiO_2 and bentonite NMs showed low variation in ?P, with percentages of 2.86% (25.6 mg/L) and 4.55% (256 mg/L) for TiO_2, and -4.95% (25.6 mg/L) and -6.48% (256 mg/L) for bentonite. The hydrodynamic size of the particles was notably variable. TEM results indicate a more efficient dispersion of MWCNTs with NOM. These results will integrate the toxicity assessment results for D. magna exposed to these NMs under the same experimental setup. (ecotoxicity results presented at SETAC Seville). The combination of previous ecotoxicity results with this characterisation data provides important information and recommendations, which are being included in the OECD GD No 317 as annexes to aid in standardising techniques and methodologies for assessing NM hazards in D. magna.

6.10.P-Th370 Effects of Naproxen in Soluble vs. Nanostructured Form on the Zebrafish Danio rerio

Fabiana Vieira, *Diana Isabel Oliveira Carneiro, Maria D Pavlaki, Roberto Martins, João Tedim and Susana Loureiro, University of Aveiro, Portugal*

Inorganic nanoengineered drug delivery systems (NDDS) have been designed and used to release active ingredients in a controlled way, thereby ensuring the optimal drug concentration in the organism. Due to their widespread use, these NDDS may end up in wastewater. Since wastewater treatment plants (WWTP) often cannot adequately remove them, they can reach aquatic organisms and cause undesired effects. The ecotoxicological assessment of such novel pharmaceuticals is, thus, crucial to derive an accurate environmental risk assessment (ERA) by developing and/or adapting standardized testing procedures and improving risk-based regulations. Therefore, the present study aims to evaluate the effects of naproxen, a non-steroidal anti-inflammatory drug, in zebrafish (Danio rerio), in its sodium salt form as well as in a novel nanostructured form. The nanoform was achieved by naproxen intercalation in magnesium and aluminium-layered double hydroxides (LDH), a class of versatile stimuli-responsive anionic clays, used in a wide range of controlled release technologies.

The morphology, chemical composition, structural, textural, and thermal properties were investigated using a large suite of conventional techniques, namely TEM, SEM, ATR-FTIR, XRD, TGA, and N2 adsorption isotherms. The loading content and release profiles were also determined using UV-Vis spectroscopy. For the ecotoxicological assessment, D. rerio embryos were exposed to aqueous solutions of naproxen sodium and dispersions of LDH-Naproxen, according to the OECD 236, and lethality and malformations were assessed after 96 h of exposure. In a sublethal test, biochemical markers of oxidative stress and neurotoxicity and behavioral endpoints were determined after 120 h of exposure.

Briefly, naproxen was successfully intercalated within the LDH galleries. Additionally, results showed distinct toxicity patterns of naproxen in both soluble and nanostructured forms to D. rerio. These findings will reinforce the environmental risk assessment (ERA) of naproxen and offer key data for the future ERA of the novel NDDS, promoting the development of sustainable and safe-by-design pharmaceuticals with reduced ecological impact.

6.10.P-Th371 Holistic Assessment of a Novel Antifouling Nanoadditive Based on a Natural Compound

Maria Margarida Almeida[1], Joana Figueiredo[1], Ana S Gomes[2], Fernando Perina[1], Claudia Rocha[3], Frederico Maia[3], Marta Correia-da-Silva[2] and ***Roberto Martins***[1]*, (1) University of Aveiro, Portugal, (2) Universidade do Porto, Portugal, (3)Smallmatek - Small Materials and Technologies, Lda., Portugal,*

Marine biofouling is a natural process where fouling organisms adhere to immersed surfaces, causing extensive socio-economic and environmental impacts. Traditionally, antifouling biocides have been used in coatings to tackle this issue. However, these biocides pose environmental risks due to their persistence and toxicity. Consequently, there is a growing need for eco-friendly alternatives. Natural or Nature-inspired antifoulants (NIAFs) have emerged as a promising solution due to their lower environmental impact and sustainable synthesis. Researchers from the University of Porto have synthesized a natural compound exhibiting significant anti-macrofouling activity, low bioaccumulation potential, and preliminary low (eco)toxicity. Despite these advantages, a major challenge is expected: the premature release of this active agent from coatings due to its water solubility. Nanotechnology offers a potential solution to this problem. By immobilizing active ingredients in stimuli-responsive engineered nanomaterials (ENMs), it is possible to control their release over time, thereby extending the service life of the coatings and reducing their environmental impact. Thus, to develop long-lasting additives for coatings, this study aims to immobilize this natural antifouling agent into nanostructured materials, characterize the nanostructured forms, and assess their environmental behavior, ecotoxicity, and marine hazard compared to the soluble form.

Several nanoforms were developed with a loading content ranging from 22% to 40%. The toxicity of the soluble and most promising nanostructured forms ranged between non-toxic (EC50>100 mg/L; to the crustacean Artemia salina) to harmful (10>EC50 >100 mg/L) or toxic (1>EC50>10 mg/L) to six species, while causing significant effects in embryo-larval stages of Paracentrotus lividus (at 1 ?g/L). Remarkably, the immobilization process reduced the NIAF toxicity on three tested species compared to the soluble NIAF. One of the developed nanoforms demonstrated its potential as a promising, eco-friendly, and long-lasting antifoulant solution, having the lowest release over time and lower ecotoxicity than the other nanostructured forms. This research represents progress towards sustainable antifouling solutions, demonstrating the potential of nanotechnology to address the limitations of current biocides. Finally, this study highlights the importance of a safer-by-design approach in developing eco-friendly antifouling technologies.

6.10.P-Th372 An Assessment of the Toxicity of Nanogold Containing SARS Cov-2 Rapid Test Kits on Daphnia pulex

Rorisang Malatsi *and Tarryn Lee Botha, University of Johannesburg, South Africa*

The introduction and surge of the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2 virus) has resulted in the development and rise of various new fields of science and technology in efforts to combat it. Nanoscience and nanotechnology have emerged with materials that are essential in the fight against the Coronavirus (COVID-19). The rapid development and deployment of SARS-CoV-2 diagnostic test kits containing colloidal gold nanomaterials (nAu) has raised concerns regarding their environmental impact, particularly in aquatic ecosystems. This study evaluated the acute toxicity of the leached component in these rapid test kits on Daphnia pulex, a widely recognized bioindicator species which is sensitive to pollutants, using two exposure solutions a direct addition of test strips over exposure duration and a stock solution prepared from 138 test strips after 15 minutes of leaching. The solutions were used to expose D. pulex at varying leachate concentrations over 24 and 48 hours, monitoring immobilization as a primary toxicity indicator. Characterization of the nAu via Fourier Transform Infrared Spectroscopy (FTIR) and Dynamic Light Scattering (DLS) revealed an average particle size of 100 nm with a complex mixture of functional groups, including organic stabilizers, surfactants, and preservatives, that potentially influence their stability, reactivity, and toxicity in aquatic environments. Results indicated that nAu exposure led to significant D. pulex immobilization, with LC50 values decreasing over time, indicating heightened toxicity with prolonged exposure. Additionally, CytoViva dark-field hyperspectral microscopy confirmed the uptake and distribution of nAu in D. pulex, particularly in the digestive tract, indicating ingestion as a key exposure pathway. These findings highlight the potential risks posed by nAu-containing diagnostic kits to aquatic ecosystems. The study emphasises the need for careful assessment and regulation of nanomaterials in consumer products to prevent unintended environmental harm. Further research on long-term effects, bioaccumulation, and mitigation strategies is recommended to inform safer nanomaterial use and disposal practices.

6.10.P-Th373 Health and Environmental Issues Related To Advanced Materials: Implementation of Safe and Sustainable by Design Framework from SUNSHINE to SUNRISE Project

Andrea Brunelli[1]*, Sara Trabucco*[1]*, Elisa Giubilato*[1]*, Elena Semenzin*[1]*, Alberto Katsumiti*[2]*, Isabel Rodriguez-Llopis*[2]*, Blanca Suarez Merino*[3]*, Vicenc Pomar-Portillo*[4]*, Hubert Rauscher*[5]*, Irantzu Garmendia Aguirree*[5]*, Lisa Pizzol*[6]*, Stefano Manfredini*[7]*, Cristina Salazar Castro*[8]*, Mariajose Lopez Tendero*[9]*, Antonio Marcomini*[1]*, Danail Hristozov*[10] *and Elena Badetti*[1]*, (1)Ca' Foscari University of Venice, Italy, (2) Basque Research and Technology Alliance (BRTA), Spain, (3)TEMAS Solutions GmbH, Switzerland, (4)EMPA - Swiss Federal Laboratories for Materials Science and Technology, Switzerland, (5)European Commission, Joint Research Centre (JRC), Belgium, (6)GreenDecision S.r.l., Italy, (7)AmbrosiaLab srl, Ferrara, Italy, (8)Lurederra, Spain, (9)Laurentia Technologies sll, Spain, (10)Emerge Ltd, Bulgaria*

The safety and sustainability performances of advanced materials (AdMa) should be critically assessed throughout their lifecycle, from development to end-of-life. As engineered nanomaterials (NMs), AdMa are intentionally produced to possess unique properties that enable innovation across various industries, such as electronics, healthcare, construction, and energy. However, like NMs, the innovative nature of AdMa implies that their risk assessment is still challenging. Thus, a valuable approach to guide the development of AdMa throughout the entire value chain, minimizing their potential risks to human health and the environment could be the European Commission s Safe and Sustainable by Design (SSbD) framework for chemicals and materials. The first three (out of five) SSbD steps address different safety aspects: I) hazard assessment based on intrinsic properties; II) occupational health and safety (including exposure) during the production and processing phases; III) exposure during the final application phase. Therefore, this approach, recently adapted to multi-component nanomaterials (MCNMs) within the H2020 SUNSHINE project, could allow us to obtain useful information for AdMa safety assessment at very early stages of the innovation process. Within the recently started SUNRISE project, first efforts to assess safety of AdMa selected as case studies in SUNRISE will be devoted to extrapolate as much as possible information already available in the literature on similar materials and/or their individual components. The three case-study AdMa are designed for different industrial applications, such as offshore installations, cosmetic products and agricultural sector. This work will therefore present the selection of tools and procedures, possibly borrowed from SUNSHINE project and other recent/ongoing Horizon Europe projects, specifically designed for early-stage innovation, which will allow a preliminary assessment of AdMa safety and the identification of first recommendations for process redesign. These outcomes are expected to be integrated in the overarching Integrated Impact Assessment Framework (IIAF) to be developed in SUNRISE to support SSbD decision making for products enabled by AdMa.

Disclaimer/Disclosure: This work has received funding from the European Union s Horizon Europe Research and Innovation Programme under Grant Agreement No. 10113732 (SUNRISE project)

6.10.P-Th374 A Foresight Process To Identify Upcoming And Emerging Advanced Materials And Chemicals To Support Regulatory Preparedness

*Jamea Baker[1], **Cyrille Durand**[1], Hubert Rauscher[2], Neil Hunt[3], Amalia Munoz Pineiro[4], Lya G. Soeteman-Hernandez[5], Cornelle Noorlander[5] and Danail Hristozov[6], (1)TEMAS Solutions GmbH, Switzerland, (2)DG Joint Research Centre, Italy, (3)Yordas, United Kingdom, (4)JRC GEEL, Belgium, (5)National Institute for Public Health and the Environment (RIVM), Netherlands, (6)Emerge, Bulgaria*

The pace at which new advanced materials (AdMa) and Chemicals are being developed and brought to market continues to increase, with regulators often not being able to keep up with the pace of knowledge generation and innovation of AdMa. A Foresight Process has been developed in the Horizon 2020 SUNSHINE project (h2020sunshine.eu) as a tool to help identify upcoming and emerging AdMa and chemicals at an early stage in their development, enabling regulators to evaluate whether current regulation covers the emerging AdMa, and by extension chemicals, or if action is needed to update or modify existing regulations.

The Foresight Framework comprises two stages:

Using the TIM search engine developed by JRC (https://www.timanalytics.eu), text mining of selected literature sources such as SCOPUS, patent databases, Cordis and others is done utilizing selected search terms and strings. A targeted search brings up keywords (weak signals) which indicate possible emerging and innovative AdMa. The search can be repeated as often as needed using a more targeted set of selected search terms.

The second stage is refining and evaluation of these keywords or signals, done by a team of experts from the regulatory community, industry and others, working within a Trusted Environment, delivering a final short list of the signals corresponding to the most trending, upcoming and emerging AdMa.

A pilot study of the Foresight Process has now been completed as proof of concept, where the initial 20,000 results from the TIM search were reduced to a manageable number and refined by an expert team into five most promising signals of new and emerging AdMa.

The results of the Foresight Process can be fed into tools such as Early4AdMa, a pre-regulatory and anticipatory risk governance approach for AdMa helping regulators identify potential issues of an AdMa, related to their safety, sustainability and/ or regulatory needs, at the early stages of their development or use.

The creation of standardised, harmonised search procedures established in the SUNSHINE Foresight process, including a dedicated Trusted Environment, will enable regulators to be informed at an early stage whether innovations are sufficiently covered by existing regulatory frameworks.

The development of the Foresight Process is being continued in the Horizon Europe SUNRISE project.

Disclaimer/Disclosure: The SUNSHINE project received funding from the European Union s Horizon 2020 research and innovation programme under grant agreement No 952924

6.10.P-Th376 Design, Tiered Assessment, Benchmarking and Re-design of Advanced Materials: Two HARMLESS Case Studies

***Wendel Wohlleben**[1], Veronica Di Battista[2], Veronique Adam[3], Blanca Suarez Merino[3], Eugene van Someren[4] and Susan Dekkers[4], (1)BASF SE, Germany, (2)Arcadis, Germany, (3)TEMAS Solutions GmbH, Switzerland, (4)TNO, Netherlands*

Advanced materials are novel by their very nature. The assessment of their positive and negative impacts on sustainability, environmental safety and human safety, is more uncertain than with conventional materials, and should start at the earliest phases of innovation. Here we utilize structured guidance for the design and assessment of advanced materials, supported by categorizations and comparative screening approaches, e.g. known sustainability issues of the sector of intended use or known safety issues of specific material classes. The used tools were tiered according to the StageGate innovation process. We report on two case studies of advanced materials that replace conventional materials in different industry sectors and induce positive or negative impacts on different sustainable development goal (SDG) targets: Automotive exhaust catalyst with doped oxide-perovskites (La, Co, Ni, Pd, Pt):

- trade-offs between SDG targets 12.2 and 11.6.
- screening by prioritized NAMs: systematic trend with metal composition
- performance benefit by oxidative storage capacity, but the primary property of catalytic conversion is below benchmark.
- preferred SSbD candidate identified, but project likely to be stopped.
  Façade insulation with aerogel-fibre.mats
- trade-offs between SDG targets 11.1 and 3.9. Ambiguous on SDG 12.2 (conflicting impacts during production vs during use phase).
- screening by prioritized NAMs: similarity of released dust to known silica.
- performance benefit over conventional material.
- preferred SSbD candidate identified, recommended for pilot with exposure management for the professionals installing the panels on façades.

We strongly differentiated the depth of consideration and testing between the ideation and business case phase and laboratory phase. We performed benchmarking of performance to the conventional material, and comparative assessment by NAMs for the prioritized safety concerns (or hazard and exposure). The used tools are available at https://diamonds.tno.nl/projects/harmlesspublic. The rationale to the first of three tools is already published (DOI: 10.1039/d3en00831b). None of the screening approaches targets the level of certainty of regulatory assessment, which remains reserved for the few materials that reach market introduction.

Disclaimer/Disclosure: VDB and WW are employees of BASF SE, a company marketing conventional and advanced material. The research for this work has received funding from the European Union s Horizon 2020 research and innovation program under grant agreement No 953183 (HARMLESS).

6.10.P-Th377 Advanced Materials (nanoagrochemicals) in the Triple Planetary Crisis Perspective: Impact of Temperature Change and Pollution on Common Soil Invertebrates

*Sekerani B Chidiamassamba[1], Susana I.L. Gomes[1], Janeck J Scott-Fordsmand[2] and **Monica Amorim**[1], (1)University of Aveiro, Portugal, (2)Aarhus University, Denmark*

Agricultural practices are under pressure to deliver food in more sustainable methods, less polluting, and at the same time climate change create further challenges. Advanced materials (AdMa) like nanopesticides can provide safer and more environmentally sustainable alternatives to conventional pesticides, due to their increased effectiveness, reliance on less harmful substances, and more targeted delivery. There is an absence of environmental risk assessment regarding the impact of AdMa pollution and climate changes, in particular on important groups of soil-dwelling organisms.

Karate Zeon®, a commercial insecticide with reported nanofeatures was investigated, using the soil model invertebrate Enchytraeus crypticus (Oligochaeta) using LUFA 2.2 soil. This was compared to the active substance lambda-cyhalothrin. Temperature variations were tested beyond the standard 20ºC: 16ºC, 20ºC and 26ºC. Testing covered a long range of endpoints and life-stages that are beyond the standard endpoints, from short- to long(er)-term exposures, including: avoidance behaviour(2 days), OECD standard reproduction test (28days): survival, reproduction, plus adults' size, and its extension (56 days): total number organisms:, and Full Life Cycle (FLC): hatching and juveniles' size (13 days), survival, reproduction and adults' size (46 days). Toxicity of Karate Zeon® changed with the different temperatures. In terms of avoidance response, unlike at 20ºC (for which no avoidance response was observed), enchytraeids tend to avoid the spiked soil at both 16 and 26ºC, with highest avoidance at 26ºC. Regarding survival and reproduction (OECD standard and its extension, and FLC test), there was an overall increase in toxicity with temperature drop from 20 to 16ºC, and a decrease in toxicity with heat, from 20 to 26ºC. Here we observed that temperature changes altered the toxicity of Karate Zeon®, as assessed based on the standard test conditions. Both the temperature increase and decrease affected the environmental toxicity of AdMa in unpredictable ways; hence there is an urgent need to narrow the current information gap concerning the interplay between the three interlinked issues constituting the Triple Planetary Crisis.

Educação e Ciência (MEC) through national funds, and the co-funding by the FEDER, within the PT2020 Partnership Agreement and Compete 2020, and received further supported from the European Commission within SUNRISE (Horizon Europe, GA No. 101137324). S.B. Chidiamassamba is funded by FCT, I.P. by a PhD grant ref. 2021.06753.BD, and S. Gomes via a research contract under the Scientific Employment Stimulus - Individual Call (CEEC Individual) - 2021.02867.CEECIND/CP1659/CT0004.

6.10.P-Th378 Sustainable Nano Strategies for Water Remediation – Estarreja as a Case Study

Ana Lopes[1], Ana Rita R. Silva[1], Fabio Yu Chen[1], Sara Cristiana Lopes Peixoto[1], Carlos Pinheiro[2], Roberto Martins[1], João Tedim[1], Susana Loureiro[1] and ***Patrícia Veríssimo Silva****[1], (1) University of Aveiro, Portugal, (2)CIIMAR, Portugal*

Seawater intrusion, eutrophication and metal contamination seriously impact coastal regions due to their location and higher industrialisation. Nanotechnology-based tools, such as layered double hydroxides (LDHs), may be remediation alternatives with higher eco-friendly potential than current options on the market. These anionic nanoclays have the capacity to exchange the stabiliser anion in their interlayers with anions in the surrounding media, such as chlorides or phosphates, constituting promise remediation solutions for waters at risk of salinisation or eutrophication. This work investigated the potential of LDHs as an environmentally safe alternative to remediate waters. Freshwaters from the Estarreja municipality (Aveiro, northern Portugal) were used as a case study due to the low-lying coastal lagoon location and historically contaminated waters from this region's intense industrial and agricultural practices. Activities involved 1) sampling water from several sites in Estarreja, 2) analysing anion and metal concentrations, 3) performing water remediation tests from three selected sites, 4) chemical analysis and ecotoxicity assessment of the remediated waters with four freshwater species: Raphidocelis subcapitata (microalgae; OECD 201), Lemna minor (macrophyte; OECD 221), Daphnia magna (OECD 202), Danio rerio (zebrafish; OECD 236). Magnesium-Aluminium LDHs stabilised by nitrates (MgAl-NO3 LDHs) in slurry or calcined form were used. Remediated samples showed similar chloride levels from the non-treated ones, while phosphate, sulphate and metal (Zn, Al, As, Fe and Mn) concentrations were generally significantly lower in the treated waters than in non-treated. Overall, daphnids survival, zebrafish survival and hatching success and the growth rate of the microalgae and the macrophyte were significantly lower in exposures to non-treated samples than in those treated with LDHs. Results show the eco-friendly potential of these LDHs to remediate waters impacted by eutrophication and metal contamination. However, more studies are needed to better understand their efficacy in remediating waters affected by salinisation. These data are important to support LDHs as an eco-friendly alternative for water remediation and their industrial application. Furthermore, these results can aid in the regulation and risk assessment of these emerging nanoforms.

6.11.P Flame Retardants Regulatory and Circular Economy Challenges

6.11.P-Tu492 An Industry Perspective - How are the Producers of Phosphorus, Inorganic and Nitrogen Flame Retardants (Pinfa) Reacting to the Regulatory and Circular Economy Challenges?

Adrian Beard*[1] and Francesca Filippini[2], (1)Clariant, Germany, (2)Cefic, Belgium*

Flame retardants (FRs) have been under scientific and regulatory scrutiny since the 1990s, following the widespread detection of certain brominated FRs in the environment and the discovery of their problematic environmental and health effects. This led to regulatory restrictions on several substances under national and regional regulations. To replace these "legacy" FRs, new products were developed, often based on non-halogenated phosphorus, nitrogen, or inorganic chemistries. However, some of these alternatives, phosphate esters and nitrogen compounds, have also been found in the environment and living organisms.

In 2009, the industry group for phosphorus, inorganic and nitrogen flame retardants (pinfa.org) was established with the mission to develop and promote sustainable flame retardants. This presentation will discuss how pinfa has responded to the European Chemicals Strategy for Sustainability by creating a roadmap with specific actions. pinfa has engaged with the European Chemicals Agency (ECHA) on their Flame Retardants Regulatory Strategy, providing input on substance grouping of phosphorus-based FRs and discussing additional data needs. Besides generating new data, pinfa emphasizes the importance of communicating existing data and contextualizing analytical findings with risk evaluation. pinfa member companies have conducted case studies on Safe and Sustainable-by-Design FRs, with some support from the Joint Research Centre (JRC). One key lesson learned is that this new approach requires practical implementation tools.

The circular economy presents challenges for plastics in general, as the wide variety of additives, fillers, and pigments complicates recycling. However, simply eliminating additives (including FRs) is not a viable solution, as they serve important purposes. pinfa has undertaken projects on mechanical recycling involving FRs and advocates for increased collaboration along the value chain and improved design for recycling to address these issues effectively.

pinfa members believe that FRs contribute to making products safer for everyone, particularly in terms of fire safety, and that their risks are very low making them safe for both the environment and humans. Nevertheless, they acknowledge the need to proactively address concerns and support appropriate regulation of FRs with critical findings.

6.11.P-Tu493 Safe and Sustainable by Design, Scoping, and Simplified Assessment of 30 Alternative Flame Retardants for Use in Polymer Insulation Foams

Ayse Ay[1]*, Susan Dekkers*[2]*, Neeraj Shandilya*[2]*, Maximilian Bernard*[3]*, Herbert Scharnagl*[3]*, Leonhard Ritter*[3]*, Tobias Moss*[4]*, Roberto Chinchilla*[4]*, Sabrina Zambotti*[5]*, Davide Lecchi*[5]*, Micaela Lorenzi*[5]*, Carl-Christoph Hohne*[6] *and Wendel Wohlleben*[1]*, (1)BASF SE, Germany, (2)TNO, Netherlands, (3)Steinbacher Dammstoff GmbH, Austria, (4)Chemische Fabrik Budenheim KG, Germany, (5)Greenchemicals Srl, Italy, (6)Fraunhofer Institute for Chemical Technology, Germany*

The European Green Deal underscores the need for a Safe and Sustainable by Design (SSbD) strategy for chemicals and innovative materials. This initiative, along with the Ecodesign for Sustainable Products Regulation, marks a significant step toward promoting environmentally friendly practices in product design and manufacturing, facilitating the transition to a more sustainable economy in Europe. To implement this strategy effectively, the Joint Research Centre (JRC), the World Business Council for Sustainable Development (WBCSD), and the European Chemical Industry Council have developed guidelines outlining criteria for SSbD and providing data-driven recommendations. However, few cases have successfully implemented SSbD in research and development projects.

The PLANETS project addresses this gap by promoting the development and implementation of straightforward, effective, and cost-efficient SSbD strategies for materials and products through a tiered approach. This begins with scoping and simplified assessments in Tier 1, followed by risk screenings combined with life-cycle assessments (LCA) using existing data in Tier 2, and culminating in experimental methods alongside comprehensive LCA in Tier 3. In this work, we focused on applying Tier 1 assessments to identify alternatives to brominated polymeric flame retardants. Halogenated flame retardants containing bromine or chlorine release free radicals that disrupt combustion but face regulatory scrutiny. Phosphorus-based flame retardants promote char formation while producing non-flammable gases. Nitrogen-based flame retardants release nitrogen gas during decomposition, helping dilute flammable gases, while inorganic flame retardants, such as aluminum hydroxide, release water vapor when heated, providing cooling effects.

We assessed over 30 SSbD alternatives to brominated flame retardants, including polyFR and HBCD, comparing alternatives such as s-triazine phosphonate, ammonium polyphosphate, organic phosphate, DOPO-P-S polymer, and styrene-organophosphorus-sulfur copolymer. The target use is in insulation foams made from polyurethane, polyethylene, and polystyrene. Alternatives were evaluated based on hazard profiles and categorized by performance, compatibility, cost, degradation products, and recyclability. By utilizing the ECOTOX and ECHA databases, along with Safety Data Sheets and the HARMLESS Decision Support System tool, we identified the most suitable alternative flame retardants.

Disclaimer/Disclosure: The research for this work has received funding from the European Union’s Horizon Europe research and innovation program under grant agreement No 101177608 (PLANETS).

6.11.P-Tu494 Quantifying Efficiency of Managing POPs Waste in the UK

Richard McKinlay*, Water Research Centre Ltd, United Kingdom*

Substances such as brominated flame retardants (BFRs), which are now restricted in use and classified as POPs, were previously added to a range of products at the point of manufacture. These legacy products are now being disposed of alongside products made after restrictions were introduced, so it is vital to determine which waste streams should be classified as POPs, to ensure they are correctly managed.

WRc has carried out several studies with support and funding from the Department for Environment, Food, and Rural Affairs (Defra), the Environment Agency and industry trade associations. Sampling and analysis of a variety of waste electrical and electronic equipment (WEEE) and waste domestic seating was conducted to quantify polybrominated diphenyl ethers (PBDEs) and hexabromocyclododecane (HBCDD).The separation efficiency of WEEE recyclers to concentrate POPs into a heavy plastic fraction to minimise the quantity of POPs waste requiring destruction was studied. The destruction efficiency of energy from waste (EfW) incineration processes, the primary disposal route for POPs waste was also calculated.

It was concluded that a number of categories of WEEE, including display equipment and small mixed WEEE (SMW) contained items with PBDEs over 1000 mg/kg and therefore should be classified as POPs waste. Similarly a number of soft furnishings samples showed elevated PBDE and HBCDD levels in textile and faux leather coverings, leading to their classification as a POPs waste.

A mass balance study demonstrated that WEEE plastic recyclers could concentrate 85 95% of POPs into a dense plastic fraction, allowing for the production of a light fraction with <100 mg/kg PBDEs to be recycled. Using a mass balance approach, it was calculated that EfWs could be used to destroy PBDEs in WEEE waste with a destruction efficiency of 99.927% to 99.952%.

The combination of studies demonstrates how the UK has identified and classified two waste streams as POPs, as well as demonstrating the efficiency of the downstream separation and ultimate destruction in existing infrastructure. Analytical challenges remain in quantifying POPs in waste, and with the expansion of substances classified as POPs and the requirement to evaluate more waste streams this will remain a highly active area of research

6.11.P-Tu495 The Emergence of Alternatives to Restricted Brominated Flame Retardants in the Irish and UK Waste Streams

Stuart Harrad Prof[1]*, Martin Sharkey*[2]*, William A. Stubbings Dr*[1]*, Daniel Drage Dr*[1] *and Marie Coggins*[2]*, (1)University of Birmingham, United Kingdom, (2)University of Galway, Ireland*

The presence of restricted brominated flame retardants (BFRs) such as hexabromocyclododecane (HBCDD) and polybrominated diphenyl ethers (PBDEs) is well-established in building insulation foam, waste electrical and electronic equipment (WEEE), end-of-life vehicle (ELV) waste, and waste furniture fabrics and foams. Given these restrictions, this paper tests the hypothesis that alternative flame retardants are increasingly to be found in such waste streams. In mixed engineering plastic from a UK WEEE recycling plant, maximum concentrations of decabromodiphenyl ethane (DBDPE) and 1,2-bis(2,4,6-tribromophenoxy) ethane (BTBPE) were 4,200 and 27,000 mg kg-1 respectively. By comparison, while trace concentrations (?1.1 mg kg-1) of pentabromobenzene (PBBz) and hexabromobenzene (HBBz) were observed, no other alternative FRs were detected. In UK waste furniture fabric covers and foams, DBDPE was detected at concentrations up to 11,200 mg kg-1. In samples of WEEE, ELV, building insulation, and soft furnishing waste from Ireland, anti-dechlorane plus and DBDPE were the only alternative FRs detected in at least one waste category at a detection frequency >20%, at maximum concentrations of 96 and 1100 mg kg-1 respectively. However, 2,4,6-tris(2,4,6-tribromophenoxy)-1,3,5- triazine (TTBP-TAZ) was detected in 3 WEEE samples at between 14,000 and 32,000 mg kg-1. Moreover, a TV contained 1,100 mg/kg DBDPE, while maximum concentrations of tris(1-chloro-2-propyl) phosphate (TCIPP), and tris(1,3-dichloro-2-propyl) phosphate (TDCIPP) in ELV foams, furniture and mattress foams, and building insulation foams were 100,000 and 340,000 mg kg-1 respectively. Finally, in foams and fabrics from waste childcare articles (e.g. car seats) collected in Ireland, there were very substantial levels of TCIPP and TDCIPP (up to 170,000 and 390,000 mg kg-1) as well as of: 2-ethylhexyl tetrabromobenzoate (EH-TBB) (100,000 mg kg-1), DBDPE (9,600 mg kg-1), and bis(2-ethylhexyl)tetrabromophthalate (BEH-TEBP) (39,000 mg kg-1). Overall, the evidence suggests a very discernible presence of HBCDD and PBDE alternatives in waste polymeric goods in Ireland and the UK. Aside of the potential environmental impacts of such alternative FRs, their presence impedes the use of screening tools such as XRF that measure Br as an indicator of whether waste complies with regulatory limits on restricted BFRs. Further studies are required to establish whether this presence is increasing over time.

6.11.P-Tu496 PBDEs in Recycled Fertilizers – Implications for the Circular Economy

Martin Sharkey[1]*, Shijie Wang*[2]*, Stuart Harrad Prof*[2]*, William A. Stubbings*[2]*, Mark Healy*[1]*, Jinxi Jin*[2] *and Marie Coggins*[1]*, (1)University of Galway, Ireland, (2)University of Birmingham, United Kingdom*

A baseline assessment of PBDEs was performed in biosolids emanating from a selection of wastewater treatment plants (WWTPs) in Ireland. 21 biosolid samples, intended for use as agricultural fertilizer, were collected from 7 WWTPs over 4-month intervals in January, May, and September 2023. Highest concentrations of BDE-209 were detected in biosolid samples penta-/octa-BDEs were comparatively low. In biosolid samples, levels of BDE-209 were on the higher end of figures reported worldwide. As legacy PBDEs have been listed as persistent organic pollutants (POPs) though no legislation currently requires monitoring for their presence in wastewater, an investigation of potential contamination of the food chain through land-spreading of biosolids on agricultural lands would be warranted. PBDEs have a propensity

for partitioning into the solid fraction of waste, though it is unclear how these chemicals partition into different fractions/matrices after the application of biosolids to land. In the transition to a circular economy, the reuse of wastewater and resulting biosolids as nutrient-rich fertilizer is highly meritorious. Further research is therefore needed to determine the environmental fate of these chemicals following the use of biosolids on agricultural lands. The relevant regulations and guidance on reuse of WWTP-derived biosolids should furthermore be updated to consider a broader suite of contaminants such as PBDEs.

Disclaimer/Disclosure: This project is funded under the EPA Research Programme 2021-2030 (2021-HE-1056) and co-funded by the Department of Agriculture, Food and the Marine. The EPA Research Programme is a Government of Ireland Initiative funded by the Department of Environment, Climate, and Communications.

6.11.P-Tu497 Questionable Safety vs. Known Risks: Reevaluating Flame Retardants in Lithium-Ion Battery Enclosures Amid New Safety Standards and Regulations

*Lydia G. Jahl[1], Jolie M. Miller[2], **Anna Shalin**[2], Anna G Soehl[1], Ariana Spentzos[1], Miriam L. Diamond[2] and Arlene Blum[1], (1)Green Science Policy Institute, United States, (2)University of Toronto, Canada*

Lithium-ion batteries are increasingly being adopted in a range of products, with forecasts suggesting that their market value will surpass $400 billion by 2030. Although lithium-ion batteries contribute to net-zero emission goals, their use can cause dangerous fires. In light of this, new safety standards and regulations are emerging that could result in the unnecessary use of flame retardants without proven fire-safety advantages. In contrast, human and environmental harms from flame retardant use are well-established. Standards do not directly mandate flame retardants; however, adding them to plastics remains a simple and cost-effective method to comply with open-flame testing requirements. Plastics that meet UL94 V-0 ratings often contain 10-20% flame retardants by weight. Major uncertainties prevail regarding the actual fire-safety efficacy of these flame-retarded enclosures, including whether they effectively stop thermal runaway or potentially contribute to increased gas and particle emissions. Publicly available data does not substantiate the fire-safety benefits, while the hazards of flame retardants are well-documented.
Many flame retardants present risks throughout the lifecycle of lithium-ion batteries, from production to disposal. Occupational exposure during manufacturing and contamination of nearby communities pose severe health and environmental threats. Flame retardants migrate from plastics over time, accumulating in buildings and ecosystems. Fires involving such chemicals yield toxic byproducts such as dioxins and furans, increasing the incidence of fire fatalities and injuries due to smoke. Furthermore, end-of-life challenges, such as impaired recycling, are exacerbated by these chemicals, and can lead to continuous exposure.
This poster will highlight concerns about the use of flame retardants in lithium-ion battery enclosures, drawing from evidence that such chemicals, while intended to meet flammability standards, may cause significant health issues without clear safety benefits. We will also present potential alternatives to the use of flame retardants. Ultimately, we aim to highlight that scientific evaluation is needed to assess the safest and most effective ways to meet fire safety standards and regulations, given the increasing use of rechargeable batteries.

6.11.P-Tu498 Legacy Flame Retardants: A Key Challenge for the Transition to a Circular Economy for Plastics in Building and Infrastructure

*Sarah Schmidt[1], Thomas Gibon[2] and **David Laner**[1], (1)University of Kassel, Germany, (2)SUSTAIN research unit, Luxembourg Institute of Science and Technology (LIST), Luxembourg*

Recycling schemes for plastics in long-lived products are challenged by the presence of legacy contaminants that have been phased out in virgin materials and are restricted in new products. An example is the brominated flame retardant hexabromocyclododecane (HBCD), which was used in insulation materials made of expanded polystyrene (EPS) and extruded polystyrene (XPS).
As part of the research project IMMEC, funded by the Luxembourg National Research Fund (FNR) and the German Research Foundation (DFG), trade-offs between the phase-out of legacy contaminants and the establishment of a circular economy are assessed for plastics in buildings and infrastructure. A high-resolution dynamic material flow model has been developed to quantify historical and potential future stocks and flows of plastics in the building and infrastructure sector in Germany, accounting for legacy contaminants. The dynamic material flow model is coupled with prospective life cycle assessment to evaluate different management strategies from a contaminant as well as from a life cycle impact perspective. HBCD in EPS and XPS insulation serves as a case example within this model.
The dynamic material flow analysis shows that, in 2023, Germany's stock of insulation materials made of EPS and XPS reached approximately 9.3 million tons, with 70% contaminated by HBCD. Although HBCD was phased out of EPS and XPS production in 2015, and recycling of HBCD-contaminated

plastics is avoided to prevent reintroducing legacy contaminants, the model indicates it will take another 35 years from now for contaminant-free waste volumes to surpass contaminated waste. While this poses a challenge to circular material management strategies, refined waste management concepts may offer pathways to phase out HBCD and simultaneously enable enhanced material recovery resulting in lower life cycle impacts.
Particularly for long-lived products like plastics in the building and infrastructure sector, the phase-out of legacy contaminants challenges the transition towards more circular material systems. As demonstrated for HBCD in insulation materials, legacy additives may contaminate waste flows for many decades. Although restrictions can accelerate the phase-out of harmful substances, they counteract efforts to close material cycles and reduce climate impacts. Therefore, comprehensive analyses are needed to identify environmentally optimal waste management approaches and to support robust decision-making.

Track 7. Moving Beyond - Cross Cutting Themes, Emerging and Transdisciplinary Topics

7.01.P Framework for Post-Conflict Environmental Damage Assessment

7.01.P-Mo474 Applying the US Natural Resource Damage Assessment Framework to Post-Conflict Damage Assessment

Richard J Wenning[1] *and Ted Tomasi*[2]*, (1)Wenning Environmental LLC, (2)Integral, Inc., USA*
Military conflicts in Ukraine and other regions worldwide highlight the social, economic, and environmental impacts on local communities, raising the question of how to quantify the damage to natural resources caused by armed conflict and implement restoration efforts. Applying a Natural Resource Damage Assessment (NRDA), similar to the method used in the US to evaluate industrial accidents, can enhance procedures implemented elsewhere. Several notable examples exist where similar principles and frameworks have been applied in arbitration and law courts to resolve international disputes, including determining post-conflict reparations. Various governments and international organizations have utilized NRDA-like approaches to assess damage to natural resources, estimate the costs of repairing, restoring, or replacing the damages, and prioritize recovery efforts. A well-informed damage and recovery assessment framework should (i) address the needs of the affected people and regions, (ii) foresee potential outcomes different from pre-conflict conditions that reflect new or evolving social needs, and (iii) guide the prioritization of reconstruction efforts based on environmental risks. The latter is especially crucial as financial and public resources may be limited. This presentation outlines an NRDA-type framework applicable to environmental assessment and recovery following armed conflict. This framework stresses the necessity of being fact-based, scientifically sound, and transparent to the extent possible. It emphasizes collaboration with international recovery efforts to rebuild critical infrastructure and restore essential environmental services (such as land safe for farming and accessible potable water) and social well-being. The goal is to provide a method to optimize available financial resources, accelerate resource recovery, and restore local communities stability and safety.

7.01.P-Mo475 Assessment of Environmental Impacts Due to the War in Ukraine

Fuyuki Hayashi[1]*, Asahi Sakuma*[2]*, Runya Liu*[1] *and Norihiro Itsubo*[1]*, (1)Waseda University, Japan, (2)National Institute of Technology, Kisarazu College, Japan*
Since the Russian invasion of Ukraine in April 2022, concerns have been raised not only about the severe humanitarian impact but also about the environmental damage caused by harm to Ukraine's biodiversity and infrastructure. Particularly regarding biodiversity, international efforts to enhance conservation have been promoted since the adoption of the Kunming-Montreal Global Biodiversity Framework as a global biodiversity target at the 15th Conference of the Parties to the Convention on Biological Diversity (COP15) held in December 2022. There are concerns that achieving the "30 by 30 target" established in this framework may be delayed due to the war.
This study focuses on the natural wildfires and infrastructure damage caused by the war to quantitatively assess its environmental impact. First, geospatial data analysis was used to identify the extent of the fires and infrastructure damage, as well as the amount of stock loss in building materials. Subsequently, Life Cycle Impact Assessment (LCIA) methodologies were employed to quantify the environmental impacts resulting from these factors.
In the regional assessment, it was found that, despite the northern and eastern regions of Ukraine being dominated by farmland, wildfires had a significant impact on grasslands and forests. This is believed to be

due to ground battles being concentrated in areas consisting of grasslands and forests, avoiding the open farmland. Additionally, the high density of vegetation in forests and grasslands likely facilitated the spread of fires.
In contrast, the southern region experienced the most significant wildfire damage in wetlands. This is thought to be the result of frequent attacks on port facilities and grain storage facilities along the Black Sea. Many wetlands in the southern region are designated as ecological reserves, raising concerns about the greater impact on these areas compared to other natural environments.
In assessing infrastructure damage, it was shown that a substantial amount of stock was lost. The reconstruction of these damaged infrastructures will require the production and transportation of additional construction materials, raising concerns about the environmental impacts associated with recovery efforts.

7.01.P-Mo476 Environmental Resilience during Prolonged Armed Conflict

*Igor LInkov[1] and **Tatiana Biloborodova**[2], (1)US Army Corps of Engineers, United States, (2)Academia, Ukraine*

The war in Ukraine has caused unprecedented damage to civilian infrastructure over extended periods. Russian artillery, drone, and missile strikes on Ukraine's energy generation and transmission systems have significantly reduced the available power supply. These prolonged attacks pose new challenges for infrastructure and environmental recovery. Developing prioritization methods for recovery is critical to building resilient systems under the pressures faced in prolonged peer and near-peer conflicts. In this presentation, we discuss two projects aimed at improving resilience to prolonged attacks. First, we describe an examination of the patterns and impacts of Russian attacks on the Ukrainian energy grid and determining which aspects of the energy infrastructure are most critical to restore in order to stabilize the overall system. Second, we explore the use of machine learning methods from drone and satellite data to prioritize environmental remediation interventions in fire-damaged areas. Specifically, this methodology attempts to use drone data to identify areas which are least likely to environmentally recover without human intervention, especially in environments where data collection would be operationally challenging. Overall, this work introduces new methods to understand the implications of a wide body of prolonged extreme events, including warfare and recurring climate extreme events such as wildfires, hurricanes, and floods.

7.02 Next Generation of Environmental Risk Assessment - From Data to Design

7.02.T-01 Development of a New Framework Advancing the Integration of New Approach Methodologies in Environmental Risk Assessment

*Bruno Campos, **Claudia Rivetti**, Geoff Hodges, Iris Muller, Predrag Kukic and Jade Houghton, Unilever, United Kingdom*

Conventional regulatory frameworks for assessing the environmental safety of chemicals are centred around the evaluation of in vivo data for standard ecologically representative species. This traditional approach is mostly based on apical effects studies performed on whole organisms. However, currently we witness a regulatory and ethical drive towards non animal approaches, incorporating New Approach Methodologies embedding greater mechanistic understanding of toxicological responses across species. Mechanistic-based approaches allow the generation of points of departure alongside the identification of the mechanisms of action across a variety of biological responses. However, there are still few examples of their implementation in Environmental Risk Assessment.
We present and discuss a conceptual framework for conducting safety assessments using a wealth of mechanistic data sources to inform safety and support the applicability of NAMS in ERA without the need for generating new animal data. We then validate the approach with a benchmarking exercise, exemplified with three case studies, including 17R-Ethinyl Estradiol, Chlorpyrifos, and Tebufenozide. The overall strategy involves the collection and integration of all available effect data across human health and the environment (including historical in vivo, in vitro, and in silico endpoints) to demonstrate the suitability of mechanistic-based information to support and strengthen current practices. The results show this process represent a valuable step forward for robust environmental safety without additional animal testing, emphasizing the need for scientific consensus and further demonstration of NAMs' biological relevance and applicability with safety decision making processes.

7.02.T-02 Leveraging Cell Painting for Cytotoxicity and Mode-Of-Action Analysis of 1085 Diverse Compounds

***Jessica Ewald**[1], Katherine Titterton[2], Alex Bauerle[2], Alex Beatson[2], Daniil Boiko[2], Ángel Alexander Cabrera[2], Jaime Cheah[3], Chrissy Crute[4], Constance Mitchell[4], Beth Cimini[3], Bram Gorissen[3], Joshua*

Austell Harrill[5], Thouis Jones[3], Konrad Karczewski[3], David Rouquie[6], Srijit Seal[3], Erin Weisbart[3], Brandon White[2], Anne Carpenter[3] and Shantanu Singh[3], (1)EMBL-EBI, Broad Institute of MIT and Harvard, United Kingdom, (2)Axiom, United States, (3)Broad Institute of MIT and Harvard, United States, (4)Health and Environmental Sciences Institute (HESI), United States, (5)US EPA, United States, (6)Bayer AG, France
There is evidence that molecular profiling techniques, applied to cell models of varying complexity, may effectively detect adverse outcomes at the cell, tissue, or even organism level. Cell Painting is an image-based profiling assay using six fluorescent dyes to measure thousands of features for eight different cell components, including intensity, shape, texture, etc. In this study, we evaluate the potential for Cell Painting to provide cytotoxicity and mode-of-action information on pharmaceutical, agrochemical, and industrial compound exposures by predicting diverse in vitro assay readouts using Cell Painting data from primary human hepatocytes exposed to 1,085 compounds (8 concentrations ranging from 0.01 to 100 µM). The in vitro assays included MTT and LDH assays that we measured, as well as publicly available ToxCast assays. We additionally investigate how different cell representations (traditional and deep learning-based) and exposure concentrations impact predictive performance. We found that Cell Painting was more sensitive than cytotoxicity assays - as judged by the number of active compounds and the relative activity concentration - suggesting that it captures rich mode-of-action signals. On average, image-based PODs were 2.5-fold lower than MTT, 7.9-fold lower than cell counts, and 15.8-fold lower than LDH. The choice of cell representation and profile summary method impacted image-based PODs, with DINO and CellProfiler able to detect activity for more compounds and at lower concentrations than CP-CNN. We evaluated the ability of Cell Painting profiles to predict the paired MTT and LDH assay readouts and found that models based on Cell Painting greatly outperformed simple models based on cell count, and that performance was similar across cell representations. For the ToxCast assays, we found that the predictive performance depended on experimental factors, with cell-based assays easier to predict than cell-free assays and liver-based assays easier to predict than assays derived from other tissues. Finally, we used the trained ToxCast assay models to predict molecular targets and modes-of-action for data-poor compounds that were not screened by ToxCast. This work will inform the future analysis of a large, multi-omics dose-response dataset generated by the OASIS Consortium consisting of Cell Painting, transcriptomics, and targeted protein data for ~1500 compounds in multiple biological contexts. This abstract does not reflect US EPA policy.

Disclaimer/Disclosure: We appreciate funding to support data analysis and interpretation from members of the OASIS Consortium (https://oasisconsortium.org/), CIHR Banting and SOT Syngenta postdoctoral fellowships to JE, and a National Institutes of Health grant (R35 GM122547) to AEC.

7.02.T-03 Combination and Interpretation of Datasets with Mechanistic Models for Informed Decision Making and Increased Certainty in Regulatory Risk Assessment

***Thomas G. Preuss** and Vanessa Roeben, Bayer AG, Germany*
The environmental risk assessment of pesticides relies on endpoints for exposure and hazard which are used to receive risk quotients. For the hazard assessment the dataset submitted by the applicant is evaluated by the risk assessor study by study, species by species and as a result a single endpoint from one study is used to derive the risk assessment.. Studies which are not meeting the reliability and relevance criteria are excluded from the analysis, which often occurs in the case of older studies. Therefore, valuable information about variability and uncertainty in the datasets for compounds is neglected or even lost. Consequently, the current regulatory system ignores a significant amount of available knowledge and information. A different approach is needed shifting to next generation environmental risk assessment, which will be accompanied by complex sets of non-animal data needing to be integrated into the regulatory system.
With this presentation we propose a different approach for the evaluation of large datasets using mechanistic effect models. With this approach, the complete dataset is used to inform the model which provides then an indication of the consistency of the data. Therefore, the model is able to investigate the full data package. If this analysis reveals a consistent pattern and the dataset is large enough, there is no need for the regulator to deep dive into the details of all underlying studies. If some of the data were incorrect or not consistent, the model would identify those as they would not fit in the overall picture. In case an inconsistency is discovered, more investigations are needed.
We will present examples of how we used this kind of approach in the registration process for our actives. Examples will cover aquatic invertebrates and bees, different models (GUTS, BeeGUTS and DEB) as well as different active ingredients.
Our study underlines the power of mechanistic modelling by integrating datasets which differ in exposure, biological level, or species. Following this approach opens the regulatory system for the next generation

risk assessment. Through the use of additional knowledge and mechanistic understanding, this approach allows to make a more robust and certain risk assessment and to integrate standard and non-standard test systems. In addition, following this approach potentially reduces resources to evaluate large datasets and makes risk assessment less complex.

7.02.T-04 Spot the Differences: Does Biotransformation Explain Sensitivity Variations in Non-Target Aquatic Arthropods to a Plant Protection Product?

***Giulia Cafiero**[1], Sanne van den Berg[1], Nick van Sabben[1], Jan Baas[1], Ivo Roessink[1], Paul van den Brink[1], Tobias Pamminger,[2] and Nico van den Brink[1], (1)Wageningen University and Research (WUR), Netherlands, (2)Bayer AG, Germany*

A major challenge in ecotoxicology is understanding why certain species are more sensitive to a given chemical than others. Typically, the effects of plant protection products (PPPs) on non-target aquatic arthropods are assessed through summary statistical metrics (e.g., NOEC, LCx). These are used either in isolation per species or combined in sensitivity distributions to inform regulatory decisions in environmental risk assessment. The impact of a chemical on different species can vary considerably and carbamates, for instance, can produce effects across aquatic invertebrate classes varying by up to four orders of magnitude between the most and least sensitive tested species. Attempts to explain and predict such sensitivity differences have traditionally relied on trait-based approaches that use morphological and ecological characteristics, while physiologically-related differences (such as biotransformation potential) have been poorly explored. Physiological traits, including a species' ability to modify or detoxify a chemical, have been shown to play a significant role in explaining toxicokinetic-related differences in sensitivity. In this study, we present the results of the exposure of six aquatic arthropod species (G. pulex, L. benedenii, H. azteca, D. magna, C. riparius, C. dipterum) to a carbamate PPP and identify the most and least sensitive species, in order to have a distribution of sensitivity. We then analyze the lethal effects with a reduced GUTS model (from the General Unified Threshold models of Survival framework) and doing so compare time-independent toxicity. In the next step, we aim to elucidate the mechanisms underlying the GUTS parameters obtained for two test species of interest. In a short-term exposure to carbaryl, we will assess following endpoints: i) uptake and elimination of the parent compound, measured through internal and external concentrations; ii) identification and internal concentrations of primary carbaryl metabolites; iii) biotransformation rates determined through in vitro and/or in vivo enzymatic assays. This methodological framework can be applied further to other species and eventually aid cross-species extrapolation, including predict toxicity in untested species. Identifying the key mechanistic determinants of toxicity, such as key elements of an adverse outcome pathway, aids cross-species extrapolation and ultimately provides a useful tool for development and regulation of safer PPPs.

7.02.T-05 Joining Structural and Genetic Similarity Modelling: Advancing QSAR for Cross-Species Toxicity Predictions

***Mirko Forastiere**, Martina G. Vijver and Marco Visser, Institute of Environmental Sciences (CML), Leiden University, Netherlands*

In silico models are a valuable resource to current ecotoxicology because of the growing interest in the principles of the 3Rs for environmental risk assessment (replacement, reduction, refinement). Within nature, a vast number of species can potentially be affected by pesticide emissions. Consequently, there is a strong and growing societal need for assessing the effects of existing and novel pesticides.
Quantitative Structure-Activity Relationship (QSAR) models use chemical features to predict the toxicity of a compound based on its structural information. These models generally make use of the features extracted from the chemical structure and some biologically relevant features.
Here we present a QSAR model that also includes a species similarity metric so that the model can output fine-tuned predicted toxicity endpoints for a given species-chemical interaction. We incorporated genetic similarity as a proxy for common physiological responses and integrated chemical and genetic features into a QSAR feedforward neural network model.
We limited our predictions to LC50 data for a wide range of species and pesticides. The feature set of this QSAR model includes chemical structural features, exposure time, and species similarity. We thoroughly validated our model with repeated cross-validation over 100 independent iterations. We tested the prediction inside our defined applicability domain (interpolation). Our model demonstrates an average R2 of 0.71 ± 10 and an RMSE of 0.82 ± 0.15 when predicting LC50 endpoints for species and chemicals in the applicability domain (interpolation). We also evaluated its potential to extrapolate an LC50 value for species outside the initial species set, or chemicals outside the initial chemical set, or for species and chemicals simultaneously outside the respective training sets.

7.02.P Next Generation of Environmental Risk Assessment - From Data to Design

7.02.P-We525 How FAIR is Ecotoxicology in the Era of Open Science?

***Eric Bollinger**, Alexander Feckler and Mirco Bundschuh, University of Kaiserslautern-Landau (RPTU), Germany*

Environmental risk assessment of tomorrow requires a reliable and accessible knowledge base today. Despite the growing recognition of this need, studies indicate that most experiments are not reproducible, partially not even by the authors of the original studies. Factors that contribute to this circumstance are plenty and go beyond experimental aspects (e.g., low replication, imprecise methods, and random variation) toward the domain of data analysis. Availability of raw data and code for data analysis are essential for transparency allowing for the identification of potential errors, evaluation of uncertainties, and integration of past with present and future scientific outcomes. In this light, the FAIR guiding principles (i.e., findable, accessible, interoperable, and reusable) were postulated in 2016. These principles aim to stimulate data availability and transparency in science. However, scientific assessments of the status quo of data and code sharing are scarce and to best of our knowledge not existing in the field of ecotoxicology. To assess (1) how frequently raw data and code of original research publications are available in ecotoxicological studies and (2) whether the FAIR principles caused a paradigm shift over the last years, we conduct a comprehensive literature review focusing on environmental studies over a period of 20 years. Since the number of publications in this time frame is in the millions, we analyze a random and representative subsample (i.e., >2000 publications). Furthermore, in case raw data and code are available, we aim to rerun the analyses to evaluate reproducibility. Our contribution will not only assess the current situation in ecotoxicology but also animate peers to share their data and code in a reproducible way by informing about the methods (e.g., version management and control) and scientific incentives to do so.

7.02.P-We526 Digital Patterns for the Detection and Prediction of Chemically Induced Endocrine Disruption (ED) in Zebrafish Embryos (DiMEP)

***Yana Streltsova**[1], Hannes Armin Reinwald[1], Paul Michaelis[2], Steve Uwa Ayobahan[3], Henner Hollert[4], Elke Eilebrecht[3], Sebastian Eilebrecht[3], Tobias Pamminger,[1] and Wibke Busch[2], (1)Bayer AG, Germany, (2)Helmholtz Center for Environmental Research (UFZ), Germany, (3) Fraunhofer Institute for Molecular Biology and Applied Ecology (IME), Germany, (4) Goethe University Frankfurt, Germany,*

Endocrine-disrupting chemicals pose a significant threat to human and environmental health, by interacting with key physiological processes such as development and reproduction. However, the current evaluation of endocrine disruption is time-consuming, costly, and heavily reliant on animal-intensive in vivo studies. However, current evaluation of endocrine impairments requires the use of large amounts of animals through experimental testing. Zebrafish embryos present a promising model for reducing traditional in vivo vertebrate studies, as they are usually not protected by the EU animal welfare regulations until they first feed independently. Recent research has demonstrated that biomarkers of endocrine activity for some modes of action can be reliably detected in fish embryos.

In this project, we build upon these initial findings to investigate whether zebrafish embryos can be used to reliably detect endocrine activity across a range of known endocrine disrupting compounds that encompass a broad spectrum of endocrine modalities. The zebrafish embryos will be exposed to endocrine-disruptive chemicals with known estrogenic, androgenic, and steroidal modalities at sub-lethal concentrations until 96 hours post-fertilization and their toxicogenomic responses (i.e., RNA-seq fingerprints) will be assessed. Our analysis will focus on identifying expression signatures that are robust and specific to endocrine activity for the investigated modalities.

If such reliable signatures exist, toxicogenomic information could provide mechanistically informed insights into the endocrine activity of the tested chemicals, optimizing the testing strategy for endocrine disruption and reducing the need for unnecessary in vivo testing in accordance with the 3R principles.

7.02.P-We527 From Regulatory Decisions to Environmental Protection. Scientific Challenges for Informative Environmental Risk-Impact Paradigms

***Jose V. Tarazona**, Ana Fernandez Agudo, Noelia Dominguez Morueco and Maria del Carmen Gonzalez Caballero, Spanish National Environmental Health Centre. Instituto de Salud Carlos III, Spain*

Our methodological capacity for conducting science-based environmental risk assessments (ERA) has significantly evolved in recent decades. In parallel, jurisdictions such as the European Union have strengthened the legislation, and environmental assessments are nowadays required for most chemicals. Nevertheless, these developments have not reverted the trend of environmental deterioration and biodiversity losses. This deterioration trend is the result of different factors including habitat loss, landscape intervention, climate change and other human interventions. Chemical pollution is identified among these factors, but due to the current ERA paradigm and despite the scientific developments we cannot quantify the actual contribution of industrial chemicals, pesticides, biocides, pharmaceuticals,

personal care products, etc. to environmental deterioration.
Our analysis suggests that the main limitation is that the current paradigm focuses on the short-term regulatory decision, e.g. authorization or use restriction, but does not allow to identify the residual risks and to integrate the risk characterizations into expected environmental impacts and their consequences. Based on this analysis, we propose the following key elements to be considered for developing a 21st century paradigm for ERA, focused on the identification of risk drivers, integration of environmental impacts at landscape levels, and the use of system-based approaches for moving from the quantification of risk to the identification of main environmental impacts and the expected short- and long-term consequences.
Key elements of the derivation of a new paradigm are the focus on New Approach Methodologies (NAMs), the consideration that in most cases the emissions and environmental effects are linked to human modified ecosystems, such as agricultural bio-systems and managed water bodies, and the integration of the environmental exposure of human subpopulations in the identification of environmental risk drivers.

Disclaimer/Disclosure: This work has been partially funded by the EU Horizon project NAMWISE Project 101191595

7.02.P-We528 FXMATE: Statistical Evaluation of Ecotoxicity Effects Made Totally Easy
***Eric Bollinger**, Dominic Englert, Felix Koenig and Jochen Zubrod, Palinera GmbH, Germany*
Chemical registration requires numerous toxicity tests, creating a significant demand for time and specialized expertise across involved institutions. Despite the guidance provided, for instance by OECD, flawed statistical analyses remain a persistent challenge, potentially compromising the accuracy of toxicity estimates and jeopardizing the protectiveness of environmental risk assessments. Current practices often rely on custom code or proprietary software, which may lack transparency and introduce errors. FXMATE is designed to address these issues as an open-source tool that offers a structured approach to guiding users toward accurate, tailored analyses by making the latest R functionality available via a dockerized interactive Shiny app. Unlike a one-size-fits-all solution, FXMATE incorporates high-quality data validation, state-of-the-art dose-response modeling, and fail-safe hypothesis testing for NOEC/LOEC estimation. By automating guideline-specific data preprocessing steps (e.g., for OECD guidelines 201 and 211) and providing a user-friendly interface, FXMATE significantly improves both the quality and efficiency of statistical analyses. Beyond these core functions, the modular structure of FXMATE ensures extendibility for evolving risk assessment needs, while already providing unique features like bootstrapping, model averaging, and containerization to enable high reproducibility. FXMATE hence updates statistical analysis of ecotoxicity data to current methodological and software standards and supports academia, regulatory agencies, and industry in guaranteeing reliable future risk assessments.

7.02.P-We529 cleanventory: Harmonized Global Chemical Inventory Data for Assessing Persistence and Mobility Hazards
***Raoul Wolf**[1], Sivani Baskaran[1], Hans Peter H. Arp[1], Emma Schymanski[2], Zhanyun Wang[3] and Sarah Hale[4], (1)Norwegian Geotechnical Institute (NGI), Norway, (2)University of Luxembourg, Luxembourg, (3)Swiss Federal Laboratories for Materials Science and Technology (EMPA), Switzerland, (4)TZW: DVGW-Technologiezentrum Wasser, Germany*
Understanding the chemical diversity regulated across global trade markets is essential for informed decision-making and advancing regulatory frameworks. However, challenges such as limited public access to official documentation and diverse data formats hinder progress. With the growing number of regulated chemicals, a harmonized system aligned with the "one substance one assessment" principle is urgently needed.

Under the newly adopted CLP hazard classes for PMT and vPvM, persistence and mobility are central to chemical risk assessment. Persistence under CLP refers to a chemical s resistance to biodegradation, while mobility describes its potential to spread in the environment, particularly to water sources like groundwater and drinking water.

The H2020 ZeroPM project addresses these challenges through the development of the "cleanventory," an open-source global chemical inventory. Following FAIR principles (Findable, Accessible, Interoperable, Reproducible), the cleanventory features a user-friendly interface (https://database.zeropm.eu), regular updates on Zenodo, and open-source code on GitHub. This database integrates harmonized data from literature, QSAR models, and regulatory sources, offering advanced analyses on persistence and mobility. It provides stakeholders with access to curated data and tools for independent replication.

The cleanventory incorporates data from 38 files representing 25 inventories across 13 trade markets, encompassing over 990,000 entries, including 225,000 unique CAS Registry Numbers. Data cleaning and harmonization were critical for compatibility and quality. Structural information was inferred using CAS numbers and names via APIs (PubChem, CAS Common Chemistry, CCTE CompTox, and NCI/CADD), returning InChI strings ranked for probability using a weighted consensus approach. Persistence and mobility data were curated from scientific literature, QSAR models, and REACH dossiers and analysed using probabilistic Bayesian models to quantify uncertainties.

The cleanventory includes over 344,000 unique InChI strings, with 126,000 identified as "most probable" structures. Initial assessments suggest that approximately 50% and 75% of entries exhibit persistence and mobility potential, respectively. The cleanventory aligns with the EU Chemical Strategy for Sustainability, supporting regulatory processes with transparent, high-quality data.

Disclaimer/Disclosure: This work is part of the project "ZeroPM: Zero pollution of persistent, mobile substances" which has received funding from the European Union s Horizon 2020 research and innovation programme under grant agreement No 101036756.

7.02.P-We530 Inter-Species Extrapolation of Toxicokinetic Data via Mechanistic Models: Benchmarking in Small Mammals

David Heckmann[1]*, Diane Lefaudeux*[2]*, Leonie Lautz*[2]*, Marco Siccardi*[2]*, Stephan Schaller*[2] *and Laura Villain*[2]*, (1)Bayer AG, Crop Science Division, Germany, (2)esqLABS GmbH, Germany*

Environmental risk assessment necessitates the evaluation of numerous species that cannot be directly tested due to ethical and resource limitations. At the same time, the efforts under the 3R (reduce, replace, refine) principle emphasize reducing in vivo tests with the help of in vitro and in silico methods. In addition to the 3R goals, such approaches have the potential to allow a more mechanistically informed (next generation) risk assessment. Such mechanistic approaches will require mechanistic computational models to allow extrapolations from in vitro to in vivo, from lab to field, and between species. One tool to perform such extrapolations are physiologically-based kinetic (PBK) models. PBK models are complex toxicokinetic (TK) models that describe the body as a multitude of interacting organs. PBK models allow for the integration of in vitro data to predict the TK profile and to put in vitro effect data into a realistic exposure context.

This study aimed to assess the data requirements and performance of PBK models in extrapolating TK data among small mammals. We parameterized PBK models for three mammal species (Rattus norvegicus, Mus musculus, Oryctolagus cuniculus) and performed cross-species extrapolations for six compounds, all six possible reference-target species combinations, and systematically omitting available (in vitro) data.
The results demonstrate a significant improvement in prediction performance over a body-weight scaled model across all data sources, with clearance data contributing most to performance. A limited in vitro dataset can yield successful extrapolation, comparable to direct fitting of target data. The analysis also indicated that performance can be reduced when extrapolating beyond the dose range of the reference data set or when saturation effects are apparent.

We established a benchmarking framework for evaluating the species-extrapolation performance and data requirements of PBK models. The findings indicate that effective extrapolation is achievable with limited in vitro data. This framework can be expanded to include additional compounds, species, and administration routes.

7.02.P-We531 Mapping Contaminated Sites and Potential Sources to Understand the Extent of Known and Potential Contamination in the EU

Juliane Gluge[1]*, Martin Scheringer*[1]*, Nathalie Briels*[2]*, Veronika Spirova*[3]*, Hans Peter H. Arp*[4]*, Silke Gabbert*[5]*, Hana Horvathova*[3]*, Anela Kaurin*[6]*, Simon Gluhar*[6]*, Grega E. Volgar*[6]*,* ***Naila Sumreen Hina***[7] *and Ali Kanso*[8]*, (1)ETH Zurich, Switzerland, (2)ARCHE Consulting, Ghent (Wondelgem), Belgium, (3)Comenius University in Bratislava, Slovakia, (4)Norwegian Geotechnical Institute (NGI), Norway, (5)Dutch National Institute for Public Health and the Environment (RIVM), Netherlands, (6)Envit Ltd., Slovenia, (7)Eidgenossische Technische Hochschule (ETH), Switzerland, (8)Microhumus, Nancy, France*

The EU faces a critical challenge with an estimated 2.8 million contaminated sites requiring environmental action. Despite this, there are still significant gaps in data on key issues such as soil pollution. To address this issue, an EU-wide harmonized database is required to effectively identify contaminated sites and plan remediation and restoration.

In this project, data from national inventories, the scientific literature, reports from national authorities, and other literature on pollution activities and associated contaminants are collected to map contaminated sites for per- and polyfluoroalkyl substances (PFASs), petroleum and coal based (PETCO) substances, metals, and organochlorine and -bromine compounds. The collected information includes key descriptors of the sites, such as contaminant identity, concentration, and nearby sources. Additional descriptors associated with the contamination such as soil properties, land use, depth of the contamination, and size of the contaminated area are also collected. To locate the source of the contamination, information from the European Pollutant Release and Transfer Register (E-PRTR) is used. The E-PRTR contains information on activities and reported emission volumes. However, it cannot be concluded from the available emission data that the activity always leads to emissions of certain substances. The extracted data show that from all facilities that report a certain activity, only a very low percentage (mostly < 5%) report emissions of the same substance. However, the emission data from the E-PRTR are still used in the project to identify potentially contaminated sites.
The final produced maps and the collected data can be used for spatial planning, risk assessment and socio-economic analysis for evaluating and prioritizing soil remediation strategies. These maps will therefore be an important tool to achieve healthy soils in the future. In the poster we will show the data collected thus far, address challenges in obtaining the data and present contaminated hot spots in Europe.

7.02.P-We532 Enhancing Environmental Exposure Assessments: A Tiered Approach for Downstream Users in the REACH Context, a Case Study with the Cosmetic Industry
***Harald Streicher**, Diego Robles and Lale Carstensen, Beiersdorf AG, Germany*
Given that REACH is a chemicals regulation, it is well understood that environmental exposure assessment was predominantly designed for chemical manufacturers, employing a total tonnage approach that aggregates data across diverse sectors. While essential for regulatory compliance, this method often fails to provide actionable insights for downstream users, such as cosmetic manufacturers, who need specific exposure data relevant to their products. For instance, UV filters used in cosmetics may also be found in coatings and plastics, each with distinct exposure routes. This highlights the inadequacy of a one-size-fits-all tonnage approach, particularly for substances washed down the drain after use.
To address these limitations, we propose a tiered framework for environmental exposure assessment tailored to the cosmetic industry. The first tier focuses on an industry sector approach, concentrating on realistic volumes of down-the-drain exposure specific to cosmetics. However, obtaining accurate tonnage data can be challenging. Therefore, we recommend a company-specific tier, allowing individual companies to assess their actual usage tonnages. This enables precise calculations of respective environmental impact and facilitates tracking changes in ingredient use over time, serving as a basis for estimating industry sector volumes based on market share.
Moreover, the REACH total tonnage approach yields average exposure predictions for Europe, which may not reflect local realities. The diversity of river catchments complicates the correlation between predicted environmental concentrations (PEC) and actual measured concentrations (MEC). To enhance accuracy, we advocate integrating data from human safety assessments, such as the SCCS Notes of Guidance, which provide average usage values for cosmetic categories. By combining these values with default effluent data and environmental fate models like SIMPLETREAT, we can achieve a more accurate picture of environmental concentrations, further refined by incorporating country-specific dilution factors and wastewater treatment facility percentages.
In conclusion, we advocate for a comprehensive exposure assessment strategy that incorporates total tonnage, industry sector, and company-specific approaches. This multilevel approach enables downstream users to make ingredient decisions that align with environmental safety goals.

7.02.P-We533 Croplife Europe: Problem Formulation Approach for Environmental Testing Strategy of Biochemical Plant Protection Products
*Sian Ellis[1], **James Robert Wheeler**[2] and Seamus Taylor[3], (1)Corteva Agriscience, United States, (2)Shell International, United Kingdom, (3)Adama, Israel*
Biochemicals such as plant extracts, RNA, peptides and microbial metabolites have been gaining importance for their use as crop protection products. They are recognized to provide a sustainable alternative to synthetic pesticides and provide farmers with valuable options for pest management strategies.

However, there are concerns that the approval of biochemicals in the EU has been limited, the main challenges include the extensive data requirements and use of 1107/2009 which was not specifically designed for biochemical products. Croplife Europe have therefore developed a proposal for the environmental risk assessments of biochemicals, based on a problem formulation approach which allows for a more targeted and adaptable testing strategy. Instead of establishing minimum risk in all possible aspects of environmental risk the scope is to use all available information on the biochemical to characterize the product e.g. natural occurrence, mode of action, stability etc to identify potential hazards to non-target species, and to determine if there is a viable exposure pathway to those species based on its intended application method.

Using a tiered approach to the assessment, with data added to address any uncertainty for non-target effects or to refine the exposure assessment, the aim of this assessment is to ensure safe use can be confirmed using a targeted and efficient data set. This method provides a transparent approach using dependable scientific assessment. CLE aims to promote the innovation of novel biopesticides is encouraged with an adaptable yet robust regulatory process.

7.02.P-We534 Promises and Challenges on the Way to the Next Generation of Environmental Risk Assessment for Pesticides

*Nina Hallmark and **Tobias Pamminger**, Environmental Safety, Bayer AG, Germany*

Globally, environmental risk assessment (ERA) methodology is deeply rooted in the long-standing societal concern about the hazards of manmade chemicals and their potential risks to the environment.

Traditional ERA frameworks are based on laboratory-based hazard characterization data, typically combined with worst-case environmental exposure estimates. The methods used to develop these data have continuously evolved e.g., in vitro toxicity testing, ecological modelling, environmental fate modelling, satellite supported landscape mapping, and many others. Therefore, as we progress into the 21st century and further information types and quantity become available it becomes clear that combined with changes in societal expectations linked to broader information access e.g., via on-line sources, an updated risk assessment paradigm is needed.

his new ERA framework must be fit for contemporary challenges and expectations as the underlying societal drive for minimal unintended impact on human or environmental health and safety is increasing too.

The paradigm of risk assessment applied to chemical safety is changing. A next generation risk assessment paradigm is emerging, led by the cosmetics sector and focused on human safety. For environmental safety assessment application of NGRA (NGeRA), the human safety approach cannot be copied as the level of data and subsequent assessment for individual organisms in needs to be extrapolated across vastly different and numerous species. Instead, the focus will be on creating models and frameworks that can be adapted and applied across various species and scenarios. This approach allows for a more scalable and efficient assessment process, ensuring that environmental safety standards are met without the need for exhaustive individual-level data for every species.

This is an opportune time for discission within the safety science and research communities to design and implement the tools to enable the use of the best science available in chemical safety assessments. And then convince the regulating authorities.

Disclaimer/Disclosure: NH and TP work for Bayer AG a manufacturer of plant protection products.

7.02.P-We535 Next Generation Risk Assessment Case Study on Biocides Regulated under K-BPR: A Role of NAMs Data in Regulatory Decision-Making

***Donghyeon Kim** and Jinhee Choi, University of Seoul, Korea, Republic of*

New Approach Methodologies (NAMs) include a variety of non-animal testing techniques such as in silico, in chemico, and in vitro methods. Despite their potential, NAMs data are often underutilized in regulatory decisions due to concerns about reliability. This study investigates the role of NAMs in assessing the hazard potential of biocides regulated under the Consumer Chemical Products and Biocides Safety Act (K-BPR). A systematic analysis was conducted using ToxCast/Tox21 bioactivity data and non-standardized data from literature focusing on human toxicity endpoints relevant to K-BPR regulations. By comparing hazard assessment outcomes from the EU-BPR report, where biocides had been previously evaluated, with NAMs data from ToxCast/Tox21 and the non-standardized data, several inconsistencies were identified. For instance, while the EU-BPR classified azole fungicides as non-carcinogenic and non-genotoxic, multiple in vitro studies indicated evidence of DNA damage. Similarly, developmental toxicity concerns highlighted by the EU-BPR were corroborated by findings of cytotoxicity in human placental cells. Moreover, although rat studies reported no neurotoxicity, NAMs data revealed positive cytotoxicity in human neuroblastoma cells. This case study underscores the importance of integrating NAMs data into chemical hazard assessments to avoid underestimating risks. It highlights the potential of NAMs to enhance the accuracy of chemical risk assessments and advocates for their broader acceptance in regulatory frameworks.

7.02.P-We536 EMBL AgriData Platform - Delivering Safe Food And Environmental Health

Matthew Hall[1]*, Birgit Birgit Kerber*[2]*, Sarah Dyer*[1]*, Emily Pomeroy*[1]*, Laurene Ramos Martins*[2] *and Effie Mutasa-Gottgens*[1]*, (1)EMBL-EBI, United Kingdom, (2)EMBLEM, Germany*

Introduction: Feeding a growing global population amidst climate change is a critical challenge. Climate resilient crops are increasingly required, together with environmentally benign pest and disease control strategies that are in synergy with the agricultural ecosystem. The European Bioinformatics Institute s (EMBL-EBI) AgriData Platform aims to optimize agricultural research and development (R&D) through effective management of agricultural biodata.

AgriData Platform Features: With EMBL-EBI data resources at its foundation, the ADP will boast several core features essential to its success. Firstly, it will integrate diverse data types beyond genetics, including environmental factors like climate, soil quality (type, ecological diversity at the microbial level, its nutritional potential for growing crops etc), farming practices and safety of pesticides. This holistic approach ensures a comprehensive understanding of the challenges and opportunities for plant breeding, crop protection and agronomy. Secondly, it will provide user-friendly computational tools to analyse and interpret integrated data, catering to users with varying levels of expertise. Thirdly, the platform will be designed to be sustainable and scalable, accommodating the incorporation of proprietary data from commercial organisations. Lastly, it will engender collaboration between industry (across agri-tech R&D sectors) and academia, leveraging EMBL-EBI s expertise of building data platforms in the biomedical sector for Open Targets.

Conclusions: EMBL-EBI s AgriData Platform aims to address global food security challenges through optimised agricultural research and data-driven innovation. ADP aims to create sustainable, high-quality data resources and computational tools, fostering cross-industry collaboration and driving impactful solutions in agricultural R&D.

7.03.P Health and Well-Being Effects of Blue Spaces: The Ocean-Human Health Nexus in an Ocean Under Stress

7.03.P-Tu499 From the Blue Gym to Blue Health, Blue Communities and Blue Prescriptions: 15 Years of Promoting the Oceans for Human Health

Mathew White[1] *and Lora Fleming*[2]*, (1)University of Vienna, Austria, (2)University of Exeter, United Kingdom*

Much of the focus of the field of Oceans and Human Health (OHH) has been on the risks and threats to public health including a wide array of chemical and microbial pollution, invasive species, harmful algal blooms, sea level rise, flooding etc. But our seas and oceans also have numerous benefits for human health and well-being; there are reasons why coastal regions are the most visited holiday destinations globally, and why house prices on the coast are often higher than inland. While fully recognising the risks, it is also important not to lose sight of the benefits, not least because one the main drivers of environmental protection is the desire to avoid benefit loss. This talk will present highlights from a 15yr research programme focusing on these benefits, especially the relatively intangible benefits to mental health and well-being. It will begin by detailing the Blue Gym project which was the first to show that living near the coast was associated with better health across several countries in the world and to identify the main four pathways why this might be: a) greater levels of physical exercise; b) better social and community relations; c) lower levels of stress and mental distress; and d) better biopsychosocial resilience. It will then introduce three multi-country, multi-disciplinary, European Union funded (H2020/Horizon Europe) research projects: BlueHealth, SOPHIE (Seas Oceans and Public Health in Europe), and RESONATE (Building individual and community RESilience thrOugh NATurE-based therapies); and one UK Govt. funded project working with coastal communities in South East Asia (Blue Communities). In all four projects attempts are made to understand the benefits to public health from interactions with our seas and oceans, alongside the more widely discussed risks. For instance, while a traditional approach may look at the number of hospital admissions from exposure to marine pollutants, we balance this with estimates of health care savings arising from population levels of physical activity at the coast. As well as providing systematic multi-method evidence of the various benefits of living near and interacting with the sea, the talk will also cover a range of individual, local and societal level interventions to improve access and exposure to (safe) marine settings to support and improve population health especially among more vulnerable communities.

Disclaimer/Disclosure: The research presented was supported by the European Union's Horizon 2020 research and innovation programme Grant Agreement Nos.: 666773 (BlueHealth) & 774567 (Seas Oceans and Public Health in Europe (SOPHIE), the European Union's Horizon Europe research and innovation programme grant agreement No.:101081420 (RESONATE: Building individual and community RESilience through NATurE-based therapies), and the Global Challenges Research Fund (GCRF) programme, United Kingdom Research and Innovation (UKRI) under grant agreement NE/P021107/1 (Blue Communities).

7.03.P-Tu500 The Coastal Exposome: Investigating the Link Between Sea Spray Aerosols and Human Health Benefits

***Silke Lambert**, Jan G. Bourgois, Greet Cardon, Colin Janssen and Jana Asselman, Ghent University, Belgium*

Oceans produce sea spray aerosols (SSAs) by bursting bubbles from breaking waves. SSAs are a complex mixture of inorganic salts, marine microbiota and bioactive molecules. Inhalation of low concentrations of these marine microbiota and bioactive molecules by acute and/or chronic exposure to coastal environments can potentially interact with cell signaling pathways, leading to positive health effects. Our research group previously demonstrated potential beneficial health effects of SSAs in vitro through inhibition of the Mammalian Target of Rapamycin (mTOR) pathway. mTOR is a key cell signaling pathway, regulating cell proliferation, autophagy and apoptosis. It has been associated with cancer, arthritis, insuline resistance and osteoporosis. At present, it remains unclear however which marine microbiota and bioactive molecules have an effect on the mTOR pathway and to what extent they are able to interact with the mTOR pathway in vivo.

7.03.P-Tu501 The Social Structuring of Coastal Visitation Behavior

***Alexander Hooyberg**[1], Stefaan De Henauw[1], Gert Everaert[2], Nathalie Michels[1] and Henk Roose[1], (1)Ghent University, Belgium, (2)Flanders Marine Institute (VLIZ), Belgium*

Half of all recreational tourism involves a coastal destination, and increasing evidence shows that coastal nature provides various benefits for health and well-being. Yet, the diverse behaviors at the coast have remained poorly mapped. Following Bourdieu s distinction theory, we hypothesized the existence of key structuring patterns in visitors' activities and social interactions at the coast and clear associations with visitors demographic, socio-economic, and health characteristics. Using data collected in Belgium from 2022 (N=1302), we found four structuring dimensions based on visit frequency, preference for beaches vs. built environments, visits with family vs. friends/alone, and socialization vs. exploration. We also segmented five types of visitors: Salty Socializers, Family Trippers, Singles In The City, Senior Foodies, and Lone Roamers. Visitors behavior varied with age, household situation, and level of social support. Our findings illuminate the pivotal role of citizens social capital in understanding visitors' exposome at the coast and repercussions for health.

7.03.P-Tu502 Assessing the Emotional Impact of Landscape Features on Well-being: An Online Video Experiment Across Flanders

***Yangyang Shi**, Filip Raes and Ben Somers, KU Leuven, Belgium*

Both green and blue spaces play crucial roles in supporting emotional well-being. However, the specific landscape features that contribute to these benefits remain unclear, with most research relying on site-specific experiments. To bridge these gaps, our study employs an online video experiment across Flanders to investigate how the proportion of green-blue spaces and soundscapes shape individual s emotional health. Participants (n=571) are recruited through online platforms, social networks, and offline posters. Each participant is randomly assigned to watch one of the designed videos, assess their emotional states both before and after viewing, and complete a follow-up questionnaire. We address two primary research questions: (1) How do visual and auditory characteristics independently and interactively influence individual s emotional states in urban and natural environments? (2) Does combining blue and green spaces provide greater emotional benefits than a single type of space? We have registered this study on OSF (https://osf.io/d4fzu) and are currently in the data collection phase. Our data analysis will examine the following hypotheses:

H1: Participants exposed to a natural environment with natural sounds will experience significantly greatest emotional benefits, including an increase in positive affect, a decrease in negative affect, and a reduction in worry, compared to all other conditions (i.e. natural environments with urban noise or no sound, urban or office environments with urban noise, natural sounds, or no sound).
H2: In urban environments, exposure to natural sounds will result in significantly greater emotional benefits (as defined in H1) compared to exposure to urban noise or no sound.
H3: Natural sounds in an urban environment will result in significantly greater emotional benefits (as defined in H1) than urban sounds in a natural environment.
H4: Participants exposed to environments with a combination of blue and green spaces will report significantly greater emotional benefits (as defined in H1) compared to those exposed to environments with only blue or only green spaces.

This study aims to deepen scientific understanding of how specific landscape features impact emotional health, which contributes valuable insights for urban planning. The results may help shape city planning guidelines to optimize urban spaces and therefore enhance the mental health benefits associated with green and blue spaces.

7.03.P-Tu503 Ocean and Health: A Paradigm to Face the Challenge of Sustainable Development Goals (SDGs) at Plentzia Marine Station (PiE-UPV/EHU)

Manu Soto, *Oihane Diaz de Cerio, Ibon Cancio, Nestor Etxebarria and Ionan Marigomez, University of the Basque Country (UPV/EHU), Spain*

Plentzia Marine Station (PiE-UPV/EHU) is integrated in the European Research Infrastructure European Marine Biological Resource Centre (EMBRC, www.embrc.eu), established in 2018 with a missión to provide research services to foster fundamental and applied marine biology and ecology research and to promote blue biotechnologies. The motto of PiE-UPV/EHU Ocean and health is related to the holistic concept of One health , globally and recently adopted by scientific and political communities. It implies that connections between human and living organisms and their shared environment are essential for well-being. Health must be understood comprehensively in order to protect the environment and humans. For instance, health means healthy food and aquaculture is relevant in the European Farm to Fork strategy. One of the fields with most potential for improving sustainability of aquaculture is the research of innovative feeds based on alternative ingredients and on non-carnivorous target species. PiE-UPV/EHU together with other entities in the Basque Country is conducting research towards on the intensive culturing of the omnivorous mugilid thicklip grey mullet Chelon labrosus (AKURA project) since 2017. In addition, SLOW ALGA Project initiated in 2021 explots the characteristics of algae from the Basque Coast to explore the possibility of creating km 0 products to support the Basque gastronomic ecosystem and generate healthy food with high nutritional value. In addition, research groups from the Basque Science &Technology Network (Neiker, BC3, UPV/EHU, PiE-UPV/EHU) are integrated in the Joint Research Laboratory "Environmental Antibiotic Resistance" developing joint activities on the underlying One Health paradigm. Within the EMBRC and UN Ocean´s Decade endorsed activity EMO-BON PiE-UPV/EHU is also involved on pan-european marine biodiversity monitoring program based on omics techniques. Within these activities, the aim is to share experience and scientific interests and protocols to offer holistic solutions to problems that affect the one-health context. The main contribution comes from the European project BlueAdapt, led by BC3, and the Spanish project HOBE, led by both PiE-UPV/EHU and BC3, working together to establish Plentzia Bay as One Health Observatory (or Living Lab) where the land-sea transition can be studied with special attention to aspects such as the horizontal gene transfer of antibiotic resistance genes between land and marine microorganisms.

Disclaimer/Disclosure: Fundings: AKURA and Slow Alga projects by Basque Government; HOBE project "One Health Observatory Lighthouse" by Spanish Ministry; Bluedadpt ("Reducing climate based health risks in blue environments: Adapting to the climate change impacts on coastal pathogens) by EU.

7.03.P-Tu504 Using Wearable Technology to Assess Physiological and Cognitive Health Effects of Coastal Walking Exposure in Older Adults: A Field Experiment

Julia Kinet[1], Sara Vandamme[1], Colin Janssen[1], Greet Cardon[1], Mirko Petrovic[2], ***Gert Everaert[3]*** *and Jana Asselman[1], (1) Ghent University, Belgium, (2) Ghent University Hospital, Belgium, (3)Ocean & human health, Flanders Marine Institute (VLIZ), Belgium*

With global life expectancy rising, the incidence of chronic health conditions, such as cardiovascular disease and Alzheimer s disease, is increasing, creating a significant healthcare burden. Exposure to natural environments as a preventive health strategy shows promise for positive health effects, particularly in reducing stress and improving cognitive function. While the health effects of green spaces are well-documented, the physiological effects of coastal environments for older adults remain underexplored. This issue is especially relevant in Belgium, where a large proportion of the coastal population exceeds the age of 65. This study addresses these knowledge gaps by examining the physiological and cognitive effects of coastal walking in older adults using wearable technology. In a randomized cross-over design, 60 participants, aged 60 and older, each complete two 30-minute walks, one in a coastal environment and one in an urban environment in Ostend, with a one-week interval between sessions. Each walk is preceded by 15 minutes of sedentary exposure. Continuous measurements of heart rate variability (HRV) and electrodermal activity (EDA) are collected using the EmbracePlus wristband and the Polar H10 chestband, and GPS coordinates and movements are recorded during the walks. Salivary cortisol levels are assessed at four time points, and cognitive performance is evaluated before and after each exposure using the d2 Test of Attention and the Symbol Digit Modalities Test. Furthermore, self-reported mental health data is gathered pre- and post-exposure. In the first phase of this study, a pilot experiment with 15 participants (ages 21 56, 53% female) was conducted to test and refine the protocol. The pilot study revealed a possible familiarity bias: the urban walk had a more pronounced stress-reducing effect than the coastal walk, potentially due to participants' greater familiarity with the urban environment. Building on these findings, the current study controls for this familiarity bias, while also increasing the sample size and employing more suitable outdoor wearables. It is hypothesized that exposure to the coastal natural environment will have a more pronounced positive effect on (physiological) stress and cognitive function in older adults compared to the urban environment. This study will contribute to the growing body of research on nature-based interventions, offering potential strategies to improve health outcomes in ageing populations.

7.03.P-Tu505 The Effect of Coastal Exposure and the Role of Activation on Emotions and Emotion Regulation: an Innovative Experimental Design

*Elias De Craene[1], **Gert Everaert**[2], Ann Buysse[3] and Filip Raes[4], (1)Flanders Marine Institute (VLIZ); Ghent University; KU Leuven, Belgium, (2)Flanders Marine Institute (VLIZ), Belgium, (3)Ghent University, Belgium, (4)KU Leuven, Belgium*

Coastal environments form a unique natural landscape associated with mental health benefits, where people often report greater happiness by the coast compared to other environments. Furthermore, emotions, emotion regulation strategies (ERSs), and activation, are all linked to changes in mental health outcomes. Emotions and ERSs are an important component to the recent nature-based biopsychosocial resilience theory, a fundamental framework describing how nature exposure can promote well-being. Therefore, to gain a better understanding of the link between mental health and the coast, a significant step forward lies in examining the role of experienced emotions, ERSs, and activation in this context, an area that remains underexplored. This study aims to address this research gap through an experimental design using virtual exposure. Four conditions will be compared by combining the following elements: exposure to either a coastal or urban environment, with or without activation (resulting in a 2x2 design). Exposure will take place in a controlled setting within an immersive projection room featuring 360° videos and accompanying audio of a coastal (or urban) environment, providing an innovative solution to the limitations of picture experiments or virtual reality biases. This method should allow controlling for random, real-life disturbances, while maintaining a higher level of ecological validity compared to less immersive methods. The activation manipulation will also align with real-life contexts. Prior to exposure, a sadness induction will be conducted for standardization, and, post-exposure, emotions and ERSs will be assessed to compare outcomes across conditions. It is hypothesized that participants will experience more positive emotions and use more adaptive ERSs in the coastal exposure and activation conditions (main effects) and that this effect will be even stronger for coastal exposure and activation together (interaction effect). Ethical approval will be sought from the local ethics committee, and the study will be pre-registered to ensure transparency. Based on power calculations, the target sample size will be set. It is anticipated this study will contribute to the understanding of how exposure to a coastal environment influences emotional responses and ERSs. As such, findings may inform policymakers in designing environments that support mental well-being and may increase awareness of the potential health benefits of the coast.

Track 8. Special Sessions

8.01 - Biodiversity and Chemical Hazard/Risk Assessment: Regulatory Frameworks, Integrative Approaches and Research for a Sustainable Future

8.01.T-01 Introductory Remarks
***Romana Hornek-Gausterer**, Environment Agency Austria, Austria*

8.01.T-02 Panellist group 1: flash presentations

8.01.T-03 Discussion with Panellists group 1 and Audience
***Romana Hornek-Gausterer**, Environment Agency Austria, Austria*
1. What is the current state of ERA and biodiversity?
Discussion on the current state of chemical ERA methodologies and whether they adequately address biodiversity.
2. To which extent do we understand biodiversity and its interrelated threats?
Discussion on the conceptual understanding of threats and the extent of our knowledge about them.

8.01.T-04 Panellist group 2: flash presentations

8.01.T-05 Discussion with Panellists group 2 and Audience
***Romana Hornek-Gausterer**, Environment Agency Austria, Austria*
1.What knowledge gaps and barriers hinder effective ERA and management of biodiversity loss?
Discussion on key knowledge gaps and gaps in ERA methodologies and biodiversity management, including availability/knowledge of tools to be applied when assessing the effects on biodiversity, limited understanding of cumulative effects of chemical mixtures, challenges to extrapolate effects from laboratory to field and across species, and interactions between species and non-chemical and emerging pollutants. Challenges in predicting and mitigating biodiversity loss will also be discussed.
2. What new, innovative methodologies exist to enhance biodiversity conservation?
Discussion on biodiversity research and methodologies tailored to the evaluation of the impact on biodiversity status in ERA (prospective, retrospective or their integration, dependent on the regulatory need). Special emphasis is put on innovative solutions and methodologies, such as New Approach Methodologies (NAMs). Exploring the vision for next-generation ERA (NG-ERA) to enhance biodiversity conservation.

8.01.T-06 Concluding Remarks

8.02 - Bridging the Scientific and Regulatory Gap Towards Effective Chemical Safety Assessment

8.02.T-01 Introductory Remarks
***Marlene Ågerstrand**, Stockholm University, Stockholm, Sweden*

8.02.T-02 Metabolic disruptors: achievements and challenges
***Juliette Legler**, Institute for Risk Assessment Sciences, Utrecht University, Netherlands*
Overview of methodological challenges and achievements in characterising emerging hazards, and the subsequent regulatory challenges such as method validation and uptake of new methods into chemicals legislation.

8.02.T-03 Managing risks posed by legacy pharmaceuticals under the Water Framework Directive
***Lina Gunnarsson Kearney**, Swedish Agency for Marine and Water Management, Sweden*
Challenges for an efficient and effective assessment process, focusing on the difficulties of filling data gaps with academic data. This includes the reliability and relevance of studies, including the population relevance of study endpoints.

8.02.T-04 Panel discussion
***Jane Muncke**, Food Packaging Forum Foundation, Switzerland*
Main discussion questions:

- What structural way forward is needed to make the most of the tri-lateral (Academia-Industry-Regulators) interaction and to fill the "regulatory gap" with scientific innovation/scientific state of art?
- How to allow and facilitate the use of new methodology and non-standard endpoints in the regulatory setting?

Sub - topic 1: How to address the main hurdles, seen from the tri-lateral perspective?

- How to address hurdles on regulatory acceptance and the fit into the current regulatory landscape (i.e. regulatory perspective)?
- What hurdles to take from an academic perspective: funding, structural sustainability?
- What challenges to overcome from an industry perspective: legal certainty and technological preparedness?

Sub - topic 2: How to best integrate new scientific evidence into regulatory frameworks?

- How to use non-standard endpoints and studies in a regulatory setting?
- How to capture relevant population effects: realism in terms of methodological challenges, cost-effectiveness and feasibility?

Questions from the audience

8.02.T-05 Concluding Remarks
***Simone Rizzuto**, European Food Safety Authority (EFSA), Parma, Italy*

8.03 - European Commission Roadmap Towards Phasing Out Animal Testing for Chemical Safety Assessments: State of the Process and How Can SETAC Community Contribute

8.03.T-01 Introductory Remarks
***Georg Streck**, European Commission, Belgium*

8.03.T-02 EC commission road map process and EPAA ESA work
***Georg Streck**, European Commission, Belgium*

8.03.T-03 EPAA ESA structure and work
***Jose V. Tarazona**[1] and Bruno Campos[2], (1)Institute of Health Carlos III (ISCIII), Spain, (2)Unilever, Bedford, United Kingdom*

8.03.T-04 Discussion with Audience: Recommendations for the EC Roadmap
***Georg Streck**, European Commission - DG GROW, Belgium*
Discussion with audience: recommendations for the EC roadmap focussing on seven relevant categories: Fish acute, Bioaccumulation, Fish Chronic, Endocrine disruption, Birds and Mammals (wildlife), Validation, New Environmental Safety Paradigm
Each category will start with leading expert very briefly presenting the recommendations and asking the audience to score each category on following criteria:
*Recommendation relevance
*Recommendation priority
*Any other recommendation missing

8.03.T-05 Concluding Remarks
***Georg Streck**, European Commission, Brussels, Belgium*

8.04 - Next-Gen Environmental Science: Collaborative Networks for a Sustainable Future

8.04.T-01 Introductory Remarks
***Markus Schmitz**, Evolutionary Ecology & Environmental Toxicology, Goethe University Frankfurt, Frankfurt, Germany*

8.04.T-02 Introduction to SETAC SAC
***Markus Schmitz**[1] and Micha Wehrli[2], (1)Evolutionary Ecology & Environmental Toxicology, Goethe University Frankfurt, Frankfurt, Germany, (2)Swiss Federal Institute of Aquatic Science and Technology (Eawag), Switzerland*

8.04.T-03 Introduction to ASPIS Academy
Shaleen Glasgow

8.04.T-04 Introduction to PARC Junior Community
***Maria Tannous**, Daei, ANSES, French Agency for Food, Environmental and Occupational Health & Safety, France*

8.04.T-05 PARC II: Tissue-specific responses to a binary mixture of bisphenol A substitutes in zebrafish embryos: a focus on two estrogenic and metabolic bioassays
***Florian Geffroy**, INERIS, Ecotoxicology of Substances and Environment (ESMI) Unitt / Universite Paris Cite, Inserm UMR-S 1124, France*
Mixtures of chemicals, notably endocrine-disrupting chemicals (EDCs), represent a major issue as current regulations often underestimate their risks by assessing individual substances only. Most approaches for evaluating EDCs mixtures rely on cellular models, thereby precluding to take into account the complexity of whole-organism systems and capture potential tissue-specific interactions. In this study, we aimed to address this gap by using transgenic zebrafish embryo models to assess the effects of a binary mixture of bisphenol A substitutes, bisphenol B (BPB) and bisphenol C (BPC), on estrogenic and metabolic pathways in two distinct target organs, the brain and the intestine. Through in vivo fluorescence imaging, we observed that both BPB and BPC induced the expression of the estrogen-regulated aromatase B gene (cyp19a1b) in the brain, as well as the intestinal expression of cyp3a65, each in a concentration-dependent manner. For each substance and target gene, EC50 values were derived and used to set-up an experimental ray design for binary mixtures (5 mixture ratios chosen by considering relative potency and 5 exposure levels around the EC50. The observed tissue-specific effects of these mixtures will be compared with predictions from the commonly used “concentration addition” model for our two differentially regulated target genes. These findings could reveal new insights on mixture interactions in whole-organism systems, across differentially regulated genes expressed in two distinct organs, supporting a better hazard assessment of EDCs mixtures.

8.04.T-06 PARC I: Integrated Risk Assessment for Pyrethroids: A “Proof of Concept” approach for toxicokinetics’ supported NAM-based toxicodynamics
***Ana Fernandez Agudo**, Institute of Health Carlos III (ISCIII), Spain*
Pyrethroids are synthetic insecticides widely used in agriculture and households, raising health concerns from potential ingestion, inhalation, and skin exposure. While intended to target insect nervous systems, pyrethroids may also present neurotoxic and bioaccumulative risks to human organs such as the liver, kidneys, brain, and lungs. Traditional risk assessments often apply Paracelsus’s 16th-century principle, "the dose makes the poison," using a deterministic threshold model to determine safe exposure limits. However, emerging research challenges this paradigm, revealing that the single-substance assessment and the lack of accountability of the individual variabilities are not realistic scenarios, suggesting a need for more nuanced assessments that account for bioaccumulation and complex exposure scenarios.
This study integrates toxicokinetics and toxicodynamics using PKSim software and ToxCast data to assess six pyrethroids by organ-specific bioactivity and pathway categorization, comparing results with in vivo NOAEL benchmarks. This approach includes in vitro-in vivo comparisons to improve predictions of tissue-specific toxicity and reflects a paradigm shift toward NGRA, which incorporates probabilistic, mechanism-based models.
Combining toxicokinetics and toxicodynamics, the study identified organ-specific toxicity patterns, with simulations showing bioaccumulation risks within cells despite safe interstitial levels. PKSim and Tox21 model comparisons validated the reliability of in vitro methods in NGRA.
NGRA’s integrated, probabilistic framework refines traditional models by moving beyond fixed

thresholds, supporting more precise, organ-specific assessments and addressing limitations of Paracelsus's principle. This approach, incorporating both aggregate and mechanistic insights, offers a robust basis for chemical safety evaluations that align with real-world exposure complexities.

8.04.T-07 APSIS Academy: Advancing NAMs-based DNT risk assessment through refined biokinetic models

***Susana Proenca**, esqLABS GmbH, Netherlands*

New approach methods (NAMs) are crucial for addressing the challenges in developmental neurotoxicity (DNT) risk assessment posed by species differences and knowledge gaps. While the OECD is currently evaluating their application for DNT, there is a lack of detailed recommendations for developing and evaluating the necessary kinetic models.
The ONTOX project aims to improve in silico biokinetic models for DNT to advance the predictive potential of NAMs-based DNT risk assessment. For in vitro kinetics, an in silico model was adapted from Armitage et al. (2021) and Fischer et al. (2017), incorporating both logKow-based and polyparameter linear free energy relationships-based quantitative structure-activity relationships (QSARs) and allowing simulation of repeated exposure. Simulations of approximately 100 DNT chemicals in a typical DNT in vitro system, using this model, revealed 10-fold lower free concentration than nominal concentration for 15 % of the chemicals, highlighting the need for accurate dosimetry.
Further, comparisons of pregnancy and neonates physiologically-based kinetic (PBK) models across PK-Sim, httk, and Simulation Plus platforms revealed similarities (Cmax within 10-fold) for most chemicals but specific differences particularly for very polar and highly lipophilic chemicals, where PK-Sim exhibited relatively lower Cmax predictions. For these chemical domains, kinetic predictions are being compared to available human in vivo data, and where mispredictions are identified, the PBK model or parameterization are being adjusted accordingly.
The final aim of this study is to integrate DNT effect data with the adjusted in vitro kinetic and PBK models and evaluate different quantitative in vitro in vivo extrapolation strategies.

8.04.T-08 Closing the Circle: How SETAC and Early Career Networks Shape Environmental Science

***Markus Brinkmann**, Toxicology Centre, University of Saskatchewan, Saskatoon, Canada*

As the final speaker of this session, Dr. Markus Brinkmann, Director of the Toxicology Centre at the University of Saskatchewan, Canada, will reflect on his experiences with SETAC and its Student Advisory Council. As current co-chair of the Bioaccumulation Science Interest Group (BSIG)and as a former SAC Chair and co-host of the second Young Environmental Scientists (YES) Meeting in Landau, Dr. Brinkmann will share anecdotes and personal insights into the role of early career networks in supporting professional growth and fostering collaboration.

His talk will explore the opportunities and challenges of engaging with such networks and highlight how these experiences have influenced his own career. Dr. Brinkmann will also discuss how SETAC and its affiliated groups can continue to promote connections and provide valuable support for early career scientists navigating their paths in environmental science.

As an independent contribution to the session, this talk will set the stage for the concluding discussion. It offers a perspective on how established SETAC structures and emerging early career networks can build on their strengths to empower the next generation of researchers.

8.04.T-09 Panel discussion: SETAC ESR and other ESR associations: networking & cooperation

***Markus Schmitz**, Evolutionary Ecology & Environmental Toxicology, Goethe University Frankfurt, Frankfurt, Germany*

8.04.T-10 Concluding Remarks

8.05 - The European Green Deal (Chemicals Strategy for Sustainability): Leveraging the AI Power to Advance Biodiversity Protection

8.05.T-01 Introductory Remarks

***Michelle Bloor**, Scotlands Rural College, United Kingdom*

8.05.T-02 Anthropogenic chemicals as underestimated drivers of biodiversity loss

Ksenia J Groh, *Environmental Toxicology, Swiss Federal Institute of Aquatic Science and Technology (Eawag), Dübendorf, Switzerland*

Anthropogenic chemicals as underestimated drivers of biodiversity loss

8.05.T-04 Chemicals management and IPBES biodiversity assessment from the prospective of the business-lead author.

Marie-Helene Enrici, *Sustainability, Solvay, France*

8.05.T-06 Possible roles of mechanistic modelling in assessing chemicals as a causal factor in biodiversity loss.

Andreas Focks, *Institute of Mathematics, University of Osnabrueck, Osnabrück, Germany*

8.05.T-08 Ranking questions and moderated panel discussion

Michelle Bloor, *Scotlands Rural College, United Kingdom*

8.05.T-09 Concluding Remarks

8.06 - The Planetary Boundaries for Biodiversity in the Context of Safe and Sustainable by Design

8.06.T-01 Introductory Remarks

Annegaaike Leopold, *Calidris Environment BV, Netherlands*

8.06.T-02 Introduction to the cross-cutting issues with regard to Carrying Capacity, SSbD, Governance, Planetary Boundaries for biodiversity

Leo Posthuma, *Centre DMG, National Institute for Public Health and the Environment (RIVM), Bilthoven, Netherlands*

8.06.T-03 Pitch talks: What is essential and innovative? - A few expert perspectives

8.06.T-04 Discussion with Panellists and Audience

Annegaaike Leopold, *Calidris Environment BV, Netherlands*

Key questions to be addressed:
- What is the most urgent innovation and connection between SSbD and Planetary Boundaries that we need to make.
- What is needed to improve current regulations

8.06.T-05 Concluding Remarks
